The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked* subject immediate delivery.

	Min.	Max.
Antimony ore, 45 to 55%, per ton	*$65.00	$90.00
Arsenic, white, refined, per lb	0.04	0.05
Arsenic, red, refined, per lb	0.12	0.15
Asbestos, chrysotile	100.00	350.00
Asbestos, amphibole	5.00	7.50
Asphaltum, refined, per ton	11.50	20.00
Barium chloride, commercial, per ton	50.00	60.00
Barium sulphate (barytes), prepared, per ton	20.00	30.00
Bismuth ore, 15%, per ton	*250.00	upward
China clay, English, levigated, per ton	15.00	20.00
Chrome ore, according to quality, per ton	7.50	10.00
Cobalt metal, refined, f.o.b. London, per lb	1.90	....
Coke, foundry, per 2240 lb	12.00	15.00
Diamonds (according to size and quality):		
Borts, per carat	2.00	15.00
Carbons, per carat	55.00	80.00
Feldspar, per ton	5.00	25.00
Firebrick:		
Silica, per M	50.00	55.00
Snowball, per M	40.00	45.00
Flint pebbles for tube-mills, Danish, per 2240 lb	21.00	24.00
Fluorspar, per ton	10.00	15.00
Fuller's earth, according to quality, per ton	20.00	30.00
Gilsonite, per ton	35.00	40.00
Graphite:		
Amorphous, per lb	0.01	0.02½
Crystalline, per lb	0.04	0.13
Gypsum, per ton	5.00	7.50
Infusorial earth, per ton	10.00	15.00
Iridium	55.00	....
Magnesite, crude, per ton	5.00	7.50
Magnesite, dead calcined, per ton	20.00	25.00
Manganese ore, oxide, crude, per ton	10.00	15.00
Manganese, prepared, according to quality, per ton	50.00	75.00
Mica, according to size and quality, per lb	$0.05	$1.00
Molybdenite, 95% MoS_2, per ton	1000.00	1500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per 100 lb	2.00	3.00
Osmiridium, per oz	30.00	40.00
Platinum, native, crude, per oz	30.00	45.00
Silex lining for tube-mills, per 2240 lb	35.00	45.00
Sulphur, crude, per ton	25.00	30.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, 60%, per ton	450.00	600.00
Tungsten ore, 65%	*450.00	540.00
Uranium ore, 10% min	25.00 per unit	
Vanadium ore, 15% V_2O_5, per ton	150.00	180.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	subject negotiation	

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are f.o.b. San Francisco and subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.
Acid, sulphuric, com'l, 66°, drums, per 100 lb.	$ 0.80	$ 1.10
Acid, sulphuric, com'l, 66°, carboy, per 100 lb.	1.25	2.00
Acid, sulphuric, C. P., 9-lb. bottle, bbl., per lb.	0.13	0.18
Acid, sulphuric, C. P., bulk, carboy, per lb.	0.09½	0.12
Acid, muriatic, com'l, carboy, per 100 lb.	1.60	3.00
Acid, muriatic, C. P., 6-lb. bottle, bbl., per lb.	0.15	0.20
Acid, muriatic, C. P., bulk, carboy, per lb.	0.10½	0.15
Acid, nitric, com'l, carboy, per 100 lb.	6.00	6.50
Acid, nitric, C. P., 7-lb. bottle, bbl., per lb.	0.16	0.22
Acid, nitric, C. P., bulk, carboy, per lb*	0.12½	0.15
Argols, ground, bbl., per lb	0.10	0.20
Borax, cryst. and conc., bags, per 100 lb.	4.75	5.63
Borax, powdered, bbl., per 100 lb.	5.25	6.10
Borax glass, gd. 30 mesh, cases, tin lined, per 100 lb.	11.50	14.50
Bone ash, 60 to 80 mesh, bbl., per 100 lb.	0.50	6.50
Bromine, 1-lb. bottle, per lb.	0.55	0.65
Clay, domestic fire, sack, per 100 lb.	1.50	2.00
Cyanide, 98 to 100%, 100-lb. case, per lb.	No quotes	
Cyanide, 98 to 100%, 200-lb. case, per lb.	"	"
Cyanide, 129%, 100-lb. case, per lb.	"	"
Cyanide, 129%, 200-lb. case, per lb.	"	"
Lead acetate, brown broken, casks, per 100 lb.	9.75	12.50
Lead acetate, white broken, casks, per 100 lb.	10.87	13.50
Lead acetate, white, crystals, per 100 lb.	12.50	13.25
Lead, C. P., test., gran., per 100 lb.	13.00	15.00
Lead, C. P., sheet, per 100 lb.	15.00	18.00
Litharge, com'l, per 100 lb.	8.75	9.25
Litharge, C. P., silver free, per 100 lb.	13.00	15.00
Manganese ox., blk., dom. in bags, per ton	20.00	25.00
Manganese ox., blk., Caucasian, in casks, per ton (85% MnO_2—¾% Fe)	90.00	115.00
Nitre, double ref'd., small cryst., bbl., per 100 lb.	15.00	16.00
Nitre, double ref'd., granular, bbl., per 100 lb.	16.00	17.00
Nitre, double ref'd., powdered, bbl., per 100 lb.	16.00	17.00
Potassium bicarbonate, cryst., per 100 lb.	22.00	25.00
Potassium carbonate, calcined, per 100 lb.	30.00	40.00
Potassium permanganate, drum, per lb.	1.10	1.25
Silica, powdered, bags, per lb.	0.03	0.05
Soda, carbonate (ash), bbl., per 100 lb.	1.45	1.75
Soda, bicarbonate, bbl., per 100 lb.	2.00	2.50
Soda, caustic, ground, 98%, bbl., per 100 lb.	5.25	....
Soda, caustic, solid, 98%, drums, per 100 lb.	5.00	....
Zinc shavings, 850 fine, bbl., per 100 lb.	34.00	....
Zinc sheet, No. 9—18 by 84, drum, per 100 lb.	No quotes	

*Extra charge for packing nitric acid for shipment to conform to regulations.

In its circular of August 12, the Roessler & Hasslacher Chemical Co. of New York states that there has been no change in the general situation and market conditions continue to grow firmer. Owing to further scarcity of some chemicals, or higher prices of their raw materials, there have been advances in prices. No quotations are given in the list for cresol, manganese compounds, oxalic acid, peroxide of hydrogen, platinum products, potassium compounds, or zinc-dust. Sodium cyanide, 51-52% cyanogen, is 26c. per pound, and cyanide mixtures, 39.5% cyanogen, is 29c. per pound.

Fuming sulphuric acid has advanced about 100% in price recently. There is a great demand for it, especially from Europe.

COMPANY REPORTS

MT. MORGAN GOLD MINING COMPANY, LTD.

Report No. 58 of this Australian company covers the year ended May 30, 1915, although the acting general manager's (A. A. Boyd) report deals with the second half. In the six months the following resulted:

Development, feet	1,999
Ore reserves, tons	2,847,197
Ore smelted, tons (2.73% copper, $8.07 gold)	119,478
Ore concentrated, tons (2.14% copper, $4.92 gold)	57,974
All products smelted, tons (including Many Peaks pyrite)	154,737
Copper production, pounds	12,503,680
Gold production, ounces	69,280
For the year:	
Ore smelted and concentrated, etc., tons	423,924
Copper production, pounds	20,278,500
Gold production, ounces	116,505
Total income	$4,802,500
Net profit	802,000
Dividends	480,000
Surplus (including amount brought forward from 1913)	893,000
Excess of assets	$2,210,000

BUTTE & SUPERIOR COPPER COMPANY

The Butte & Superior Copper Co. reports as follows for the second quarter of the current year:

	Second quarter.	First quarter.
Ore milled, dry tons	124,080	117,860
Average zinc-content, per cent	17.003	17.3560
Average silver-content, ounces per ton.	8.067	7.9502
Zinc concentrate produced, tons	35,840	35,317
Average zinc in concentrate, per cent.	52.706	52.9246
Zinc in concentrate, pounds	37,780,020	37,382,742
Silver in concentrate, ounces per ton.	22.714	22.6488
Mill recovery, per cent	89.536	91.3190
Mining cost per ton	$3.3816	$3.0005
Milling cost per ton	1.8108	1.8659
Total cost per ton	$5.1924	$4.8664
Net value of zinc concentrate at mill	$2,509,229	$1,792,434
Net value of lead concentrate at mill, and of residue	230,293	212,357
Miscellaneous income	11,899	6,719
Total net value	$2,751,423	$2,011,510
Operating charge	644,270	848,354
Profits	$2,107,153	$1,163,156

Operating costs in the first quarter include freight on concentrates and residues, which in the second quarter are deducted from value of these products.

The stated profits for the second quarter were calculated on a basis of spelter prices of 10.364c. per pound for April, 12.106c. for May, and 15.961c. for June, an average of 12.683c. for the three months, this price being somewhat lower than the average actually received for zinc sold during the quarter.

Ore treated was the largest in any previous quarter. The grade was below normal, the idea being to mine some lower-grade material when prices are high. The lower recovery is partly due to this, and partly to the new flotation plant. Development at the mine continued to open as much ore as that extracted. The report also dealt briefly with the smelting contract.

INTERSTATE-CALLAHAN CONSOLIDATED MINES COMPANY

During the second quarter of 1915 the Interstate-Callahan Consolidated Mines Co., Idaho, made the following production:

Ore mined, tons	30,595
Ore shipped to smelters, tons (44.6% lead, 21.05 oz. silver)	68
Ore shipped to smelters, tons (49.74% zinc)	2,834
Ore milled, tons (27.8% zinc)	27,235
Concentrate produced:	
Lead, tons (59.49% lead, 26.72 oz. silver)	851
Zinc, tons (48.24% zinc)	11,399
Mill recovery, per cent	78.28
Cost per ton:	
Mining	$3.070
Milling	0.672
Transport, etc.	1.267
Total	$5.009
Profit	$1,126,114

Up to August 2, dividends for the year total $1,610,000. Including the next two quarters the amount will be $1,840,000, while an extra of $2 per share will make a total of $2,760,000.

MINING DECISIONS

Severance of Minerals—Injury to Surface

Where the land owner has granted the surface by deed and reserved the minerals without any covenant for surface support, the surface owner cannot recover for injury to the surface on the theory of an implied covenant for surface support, but must show negligence in mining methods employed by the owners of the mineral rights in order to recover damages.

Kirwin *v.* Delaware L. & W. R. Co. (Pennsylvania), 94 Atlantic, 468. April 12, 1915.

Oil and Gas Lease—Suit to Forfeit—Parties—Rentals

In a suit by an assignee of any ordinary oil and gas lease, brought to quiet his title and enjoin the lessors from executing a second lease on the same land, it is not necessary to make the assignor a party, if it appears that the assignment is absolute and unconditional. A clause in said lease providing for forfeiture without notice upon "failure to complete a well upon the premises within the time herein specified or to pay the rentals at the time and in the manner herein provided." Held, to relate only to rentals provided to be paid for delay in drilling, and not to rentals or royalties to be paid a producing gas well.

Castle Brook Carbon Black Co. *v.* Ferrell (West Virginia), 85 Southeastern, 544. May 25, 1915.

Patent Improvements—Surveyor's Certificate

The certificate of a surveyor-general as to the requisite improvements upon or for the benefit of a lode-mining claim, made by the applicant or his grantors, is required whether the applicant be one who is relying upon an application under Section 2325, Revised Statutes, or one who seeks patent as a successful litigant in an adverse suit. Paragraph 49, of the mining regulations of March 29, 1909, is amended so as to authorize surveyors-general to accept corroborated affidavits as the basis for certificates that the improvements returned by mineral surveyors were made by the mining claimants or their grantors for the benefit of the claims surveyed, it being manifestly impracticable in many cases for the mineral surveyors to determine by inspection who made the improvements.

Archie McCormick (Land Department), 43 Land Decisions, 499. December 16, 1914.

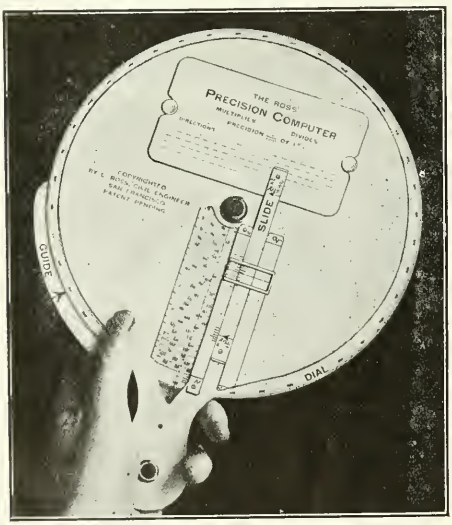
New Machines and Devices

Information based on letters and catalogues from manufacturers.

New 5-Place Computer

A new instrument, called the Precision computer, has recently been devised and placed on the market. It is compact, simple, inexpensive, and gives an accuracy equivalent to that of a slide-rule 100 ft. long. It is claimed that it combines the accuracy of 5-place, interpolated logarithms with the speed and convenience of a slide-rule, without the drawbacks of either. It solves expressions like $879.65 + 74.769 \times 72.638 = 854.58$, with an ultimate accuracy of 1/1000 of 1%, or 1 in 100,000.

The variable graduations of the ordinary slide-rule have been dropped completely. In this computer the system of graduations is absolutely uniform throughout, and is as simple as that of a 10 to the inch scale. The length of scale is 120 times



THE ROSS PRECISION COMPUTER.

as great as that of the A and B scales in the ordinary 10-in. slide-rule, although the computer is but 8-in. diameter. The accuracy of engineering data seldom exceeds 5 figures, and precise engineering computations are therefore ordinarily carried logarithmically to 5 places. The computer has been devised to give this accuracy and to combine in the same instrument means for obtaining instant, approximate results, where desired.

The computer, invented by Louis Ross, 268 Market street, San Francisco, consists of a graduated dial rotating under a slotted cover, a floating guide, and a slide mounted at the right of the slot. The dial carries a scale of numbers reading to 5 significant figures throughout, like 24364, 67342, 99893. The slide carries a miniature of the dial-scale, reading to 3 figures, and co-operates with the dial, checks and points out the precise answer, and locates its decimal point. For instant approximate results the slide alone may be used, much more directly and simply than the ordinary slide-rule.

To multiply and divide any series of numbers, it is only necessary to turn the dial so as to set each number in succession under the reading line in the slot; the answer will then appear also under the slot-line. Each turn of dial alone multiplies; of guide and dial together, divides. When data is now set on slide, one of its arrows points to the precise answer under the slot-line, gives its approximate value for a check, and by its marking, "sum, sum-1," etc., locates the decimal point in the answer.

At the left of the slot is a scale of equal parts; it co-operates with a similar scale at the rim of dial to give directly 5-place logarithms and anti-logarithms, much faster than logarithmic tables. This obviates fingering pages of tables, mental interpolations, errors, and forms, in fact, a complete table of 5-place interpolated logarithms. Powers, roots, and other complex operations may be carried out either approximately by the use of the slide alone, or to a high degree of precision by using the dial. Trigonometric calculations made by the computer give an accuracy of from 3 to 5 seconds of arc.

The computer is made of metal throughout; the graduations are engraved on silvered-metal surfaces, like a surveyor's compass or transit. It is slightly over 8-in. diameter, and weighs less than a pound. The instrument is packed securely in a flexible case, and forms a permanent, portable, and inexpensive precision computer. It is made by the Computer Manufacturing Co., 25 California street, San Francisco.

Scientific Instruments at the Exposition

Three grand prizes have been awarded the Keuffel & Esser Co. of New York and San Francisco, by the Panama-Pacific Exposition, for drawing materials and slide-rules, surveying instruments, and telescopic sights and periscopes. The exhibit in the Palace of Liberal Arts includes every requirement of the engineer for field or office work, among which are the following: the K. & E. stadia-circle, new types of slide-rules (including the chemists' duplex, Allen friction head, surveyors', Roylance electrical, K. & E. power computing, and merchants'), a display of drafting-room furniture, naval and nautical instruments, and a testing laboratory in which are shown tests necessary to insure the quality and accuracy of K. & E. products. The firm states that most of the engineering instruments used during construction of the Panama Canal were supplied by it.

Hydraulic Giants at the Exposition

At the model gravel mine in the California State Mining Bureau exhibit, in the Palace of Mines and Machinery, are several miniature giants in operation. Nearby is a full-size Joshua Hendy Iron Works, San Francisco, No. 5 latest improved, double-jointed, ball-bearing, hydraulic giant, fitted with patented Smith-LaGrange deflectors, such as are in use at the LaGrange mine in Trinity county, California. The giant has a 13-in. inlet, and is capable of taking any size nozzle up to 8-in. diameter. The giant is fitted with guide-vanes, which prevent the scattering of the water after it has issued from the nozzle, and cause it to be discharged in a more direct line. This is the type of giant which is in use in all of the hydraulic mines in the West and in Alaska, and is the same as was used at the Panama Canal.

The August issue of *Western Electric News*, of the Western Electric Co., New York, contains full particulars of the death of 468 of its Hawthorne employees, caused by the overturning of the steamer *Eastland* at Chicago on July 24.

EDITORIAL

T. A. RICKARD - Editor

THE American Institute of Mining Engineers meets in San Francisco from Thursday, the 16th inst. to Saturday, the 18th, inclusive. The American Mining Congress is called for the week following.

OUR friend, *The Mining News*, in London, states that the men working on tungsten mines in Cornwall are exempt from military service, the demand for the metal being urgent for the making of tool-steel.

UNDOUBTEDLY the War is causing hidden stores of gold to be brought into circulation. The peasantry of Europe has not learned to use safe deposits, the old stocking or its equivalent is still a receptacle for the hoard set aside for a rainy day, and now that their country is in danger, the patriotic people are bringing their gold to the bank to invest it in war loans.

HOLMES is to be commemorated fittingly by the creation of a professorship of Safety and Efficiency Engineering in the Colorado School of Mines. The professorship will bear his name and the purpose of it will be to train the students in the use of life-saving apparatus, the prevention of accidents, sanitation, ventilation, over-winding, defective wiring, the mitigation of gas and dust, and kindred subjects. The appointment has not been made as yet.

ACCORDING to *The Mining Magazine*, the rights to the Elmore flotation patents have been sold to the group of copper companies that refuses to pay royalty to the Minerals Separation company. It will be recalled that while the last decision, in March 1914, was against the Elmores as regards their bulk-oil patents of 1898 and 1901, it did not refer to their vacuum process of 1904, which antedated the basic patent (U. S. 835,120, May 29, 1905) of Minerals Separation. Presumably the purchase of the Elmore rights is to serve as munition in the campaign of litigation, by connecting the generation of air-bubbles with the production of froth, but as to this we are not informed.

CABLE dispatches state that a British syndicate has acquired control of the Swansea Vale zinc smelter, in South Wales, with the intention of increasing its capacity from 5000 to 25,000 tons of spelter per annum. This plant heretofore has been controlled by Aron Hirsch & Sohn of Halberstadt, Germany; we presume therefore that the transfer was made by consent of the British government, possibly with a guarantee of indemnity to the German owners at the close of the War, for actual payment at the present time would be prohibited by statute. We note that the new owners expect to obtain their crude ore from Burma, from which it is safe to infer that the Burma Corporation, with big zinc-lead-silver mines in the Northern Shan States, and the Zinc Corporation, controlling the South Blocks and Barrier South mines at Broken Hill, are behind the enterprise. That means Messrs. H. C. Hoover, F. A. Govett, and their associates.

WE publish a press item giving a list of increases in domestic spelter production. It is proper to add that Mr. E. V. Lanyon, of Pittsburg, Kansas, writes to say that he is adding 448 retorts only, not 1200; that the Pittsburg Zinc Co. is working to full capacity, namely 910 retorts; the Cherokee Smelting Co. is adding 224 retorts to the 672 now in operation; the Nevada Zinc Co. is building three blocks of furnaces containing 672 retorts in all, of which only one block of 224 retorts is likely to be put in operation within the next 30 to 60 days. Mr. Lanyon considers the estimate of future production much too high, mentioning unsettled labor conditions as a deterrent factor.

VAN H. MANNING has been appointed Director of the U. S. Bureau of Mines in succession to his late chief, J. A. Holmes, whom he had supported so loyally and efficiently during the latter's year of fatal illness. This appointment, by the President, will give general satisfaction, for it ensures continuity of policy and the minimum of disarrangement in the administration of the Bureau. It has been said, quite properly, that Mr. Manning is not a specialist in technology, only a capable executive. As to that, he is better equipped in one respect than in the other, but he is also a man of particular modesty, and we feel sure therefore that he will see that in his assistants he has the men that will supplement his own knowledge and experience.

ANTIMONY is in demand by the belligerents for giving brittleness, and therefore high explosive power, to the bullets in shrapnel. Hence a great scramble for the ore in the localities where it is known to occur. The old San Emidio mine in Kern county has been re-opened by San Francisco capitalists. A new mine of antimony sulphide, stibnite, has been developed in Wild Rose canyon, in the Ballarat district of San Bernardino county, and the ore is being transported on motor-trucks, of 3-ton capacity, over the 32 miles to the smelter at San Pedro, the port of Los Angeles. As much as 20 tons of high-grade ore is being taken daily out of two mines that are being worked under lease. Some of this ore is said

to run as high as 80% metal, suggesting that some of it is in oxidized form. The old Chapman smelter on Seventh and Hooper streets, in this city, is now busy, twenty small furnaces being at work. Mr. C. Solomon, Jr., a dealer in Japanese goods and hardware, is the controlling owner of this useful little smelter. He brought a large shipment of antimonial ore from Alaska and from Atlin, British Columbia, and he is getting ore from the mine at Lovelock, Nevada. He is also buying custom ore at $5 per unit, which suggests a good market somewhere in Europe.

DEMORALIZATION of foreign exchange has gone to a stage causing serious anxiety. The explanation is due to the fact that Europe's holding of gold has been hypotheeated against a disproportionate amount of paper currency and credit, while the store of gold in this country has not only grown but against it there has been issued a disproportionately small amount of currency and credit. At the beginning of the War the pound sterling was worth $7 because an exodus of gold was threatened; now the tide has turned to a disconcerting degree, the pound being worth, at the time of this writing, only $4.50. In order to restore exchange it is necessary either to import goods from Europe or buy European stocks and bonds. The continued payment for munitions and food supplies in drafts will intensify the disparity and the abnormality of exchange.

REPRESENTATIVES of the four principal engineering societies have been in conference with a view to mobilizing the engineering profession as a reserve for the engineer corps of the regular army. The chairman of the special committee appointed for this purpose is Mr. William Barclay Parsons, representing the American Society of Civil Engineers; he is co-operating with Dr. Henry S. Drinker, the president of Lehigh University, representing the American Institute of Mining Engineers, Mr. W. H. Riley of the American Society of Mechanical Engineers, Mr. Bion J. Arnold of the American Institute of Electrical Engineers, and Mr. Ralph D. Mershon of the Institute of Consulting Engineers. It is estimated that 30,000 men can be rendered available for this useful service, the details of which are being worked out in the War Department, previous to introducing a bill before Congress authorizing the formation of this engineer reserve corps.

FIVE HUNDRED million dollars, it is reported, is to be added to this country's swelling store of gold by further shipments of bullion from London to New York. Last year the world's production was $460,000,000. Of this, 63% was produced in the British dominions, 21% in the United States, and 6% in Russia. The Austro-German territories contributed 1% only. The world's stock of gold, in banks, public treasuries, and in circulation at the outbreak of the European war was estimated at $8,800,000,000, of which 80% was held within the belligerent countries, their colonies, and the United States. The Teutonic allies possessed $1,280,000,000, the British empire $1,500,000,000, the United States $1,871,000,000, while France and Russia were credited with a little over $1,000,000,000 each. Including Italy, the Allies held $3,941,000,000. During the year of war the visible supply of gold in Great Britain has increased $256,000,000, which is no more than the actual output of the mines tributary to the London market. It has been stated by *The Annalist*, for example, to which we are indebted for most of our figures, that the premium on gold has stimulated production, notably in South Africa; but this is incorrect, for no sign of increased productivity is to be observed. In 1914 the Transvaal yielded $172,602,160, as against $181,258,800 in 1913. During the first six months of 1915 the output has been $90,812,370. In July, it is true, the yield rose to $15,870,450, which is the largest since May 1913, but the increase is attributable not to the effect of any premium on gold but to the larger supply of labor, due to the idleness of the diamond mines. On the contrary, the absence of marked change in the world's gold output is the most notable fact. Owing to the geographic distribution of the principal districts, all of which are outside the war area, and the reduction of the ore at the mines or near them, together with the availability of the necessary supplies, this fundamental industry has suffered but little, except in Mexico. It is quite probable that in the wreck of international credit and the adjustment of debts at the close of the War, the production of gold will prove of immense importance.

Air-Blasts

Earth-tremors in the deep mines have again been the subject of discussion at Johannesburg, on the initiative of that free-lance, Mr. E. J. Moynihan. These sudden subsidences are due to the increasing weight of unsupported rock overhanging the mine-workings along the lode, or to the fact that, as Mr. Moynihan put it picturesquely, "the mining houses have made a tunnel in the earth, roughly speaking, thirty miles long and a few feet high. They have been widening this tunnel for over twenty years, until, on the average, it is something like a mile wide. The tunnel is also inclined in the direction of its width. Well, the roof is falling in. That is all." The diagnosis is correct: a large area of lode, dipping flatly, has been excavated, leaving a block of rock inadequately supported. At intervals and in places the pressure accumulates so as to cause a sudden collapse. That means a fall of ground, a sudden concussion of air, and the passage of vibrations that perturb those resident on the adjoining surface. Sand, the discard from the stamp-mills, has been used for filling the voids made by stoping, but this has mitigated, not stopped, the tremors or the caving that causes them. Apparently the compressibility of sand under pressure has been under-estimated, so that the filling has proved less effective than had been expected. Mr. Moynihan suggests filling the stopes with coarse rock, leaving large interstices, and

then introducing coarse-grained material, finally injecting sand to make the filling compact. In the Modderfontein B mine packs of waste-rock occupy 18% of the ground stoped; these packs are carefully built and are highly commended by the Government Mining Engineer. They, like the sand-filling, allow of a slow settling of the weight and are better therefore than pillars of unworked ground, which, as the pressure increases, eventually yield with a suddenness that is catastrophic, producing all the undesirable effects associated with tremors. The subject is one of general interest, for it concerns all deep and inclined mine-workings. In the Lake Superior copper region 'air-blasts' are as common as earthquakes in Japan; also in the deep mines of the Kolar goldfield, in India, where the sudden relief of pressure causes the detachment of pieces of rock with explosive violence. Obviously, a comparison of notes would be of service. Perhaps the principal companies operating in the three districts mentioned could come together for the purpose of appointing a commission, to which each would appoint one member, for the study of the subject and the obtaining of guidance as to the best way of meeting the difficulties inherent in the deep mining of inclined lodes.

Flotation at Broken Hill

In this issue we reproduce the major portion of an interesting paper contributed nearly two years ago to the Australasian Institute of Mining Engineers by Mr. James Hebbard, the manager of the Central Mine at Broken Hill. In this paper we are told how the zinc-lead slime obtained in the course of ordinary water concentration was treated, at first experimentally and then on a big scale, by flotation. This would be interesting in itself as coming from an engineer of high repute and long experience, but the more significant part of the paper is the information concerning the development of the process in the mill and the radical change from one phase of flotation to another. In the course of ordinary water concentration, it had been noticed that a 'froth' was formed wherever rotation, splashing, or agitation caused an entrainment or entanglement of air in the liquid pulp. This was before 1901; in that year a series of experiments was started for the purpose of "reproducing and accentuating" the conditions favorable to this froth-formation and float-concentration. Spitzkasten constituted the type of apparatus and compressed air the agent chiefly used. In this way Mr. Hebbard and his staff produced a mineral-bearing froth that was recovered as a low-grade concentrate. This is interesting because it was in 1901. Other experiments followed, including the use, in 1903, of sulphuric acid and salt-cake, after the manner of the Delprat process, which had been patented in 1902. Probably these experiments were based on information of work being done elsewhere in the Broken Hill district. Most people appear to consider that patents, like customs duties, can be disregarded without imperiling their hopes of heaven. These experiments were influenced by the large proportion of carbonates—those of lime, manganese, and lead—in the ore, which, by addition of acid, gave a plentiful liberation of carbonic acid gas. The generation of gas was hastened by the further application of direct heat under the pan in which the operation was conducted or by the introduction of live steam into the storage-tank. No agitation was used in these experiments, for a still surface was found most favorable to the maximum play of surface tension. Mr. Hebbard says that the surface tension was increased by the salts introduced, but, we venture to suggest that the opposite was the fact. However, the general result was unsatisfactory, especially as regards the separation of the finer particles of gangue from those of the metallic constituents of the ore. Apparently just at the time when this conclusion had been reached by the gentlemen at the Central mine, they received information that an important discovery had been made in London, so they awaited particulars of the new development in flotation. This discovery proved to be the so-called Cattermole or granulation or coagulation process, involving the use of soap as an emulsifying agent and the agglomeration of the flocculent oily masses that resulted therefrom. These collected the metallic particles, not to float them, but to sink them, while the gangue ascended in an up-current of water. In short, flotation was reversed. A model plant was erected at the Central mine early in 1904, and, good experimental results ensuing, a large mill was built during 1905. The details given by Mr. Hebbard are interesting, both as to the design of the plant and the method of procedure. Oleic acid, or 'red oil,' was found best and the cost of it was gradually decreased by diminishing the quantity employed from 3.5 to 0.75%. When using the smaller quantity, plus aeration, the results were excellent, "with all float concentrate, no granular material being formed." But this was no longer the Cattermole process; Mr. Hebbard was making the concentrate float, not sink; and he was not 'granulating.' We look in vain for the word 'froth' to appear. He made 'froth' in the water-concentration mill when treating the same pulp, why does not the addition of an oily emulsion, together with agitation and aeration, give him a froth that will do the work of concentration? We repeat, he got a "float concentrate" without "granular material." The temperature was raised, by the use of steam jets, in September 1905. But the official recognition of the frothing process was delayed until another 'discovery' was made, "strangely enough," says Mr. Hebbard, "at the same time both here [Broken Hill] and in the Patent Co.'s [Minerals Separation Ltd.] laboratory in London." Indeed it is strange, for Mr. Hebbard's description indicates that he had been reducing the percentage of oil, agitating, aerating, and warming his pulp-liquor until a froth was inevitable. However, we are informed that a report from Mr. A. H. Higgins was received at Broken Hill; this described the discovery made in March 1905, indicating that a decrease in oil tended to increase the float-concentrate to a point where it became advisable to reverse the Cattermole process and go back to earlier

methods of flotation, that is, buoying the metallic particles upward while encouraging the earthy particles to sink. The reduction in oil now yielded not 'granules' but a 'mineral froth.' Thus the latest phase of flotation was developed or discovered concurrently at Broken Hill and London. The result was the celebrated patent (U. S. No. 835,120, May 29, 1905) of Messrs. Sulman, Picard, and Ballot, on which the property rights of Minerals Separation are mainly based. As regards the Central mine and Mr. Hebbard, the frothing method was introduced into the mill in July 1905 and the plant was gradually adapted to the new change of procedure, so that in October flotation with simple spitz-boxes was fully established. The amount of acid apparently was so decreased that, after the second agitation, the liquor in circuit became neutral, allowing the use of iron apparatus wherever desired. Grinding-pans were found to give a product better than that from ball-mills. It would be interesting to learn whether later experience has confirmed this conclusion. Two froth-flotation plants were built. Mr. Hebbard says that during the operation of the first it was recognized that aeration was "the chief factor in flotation." This conclusion is entirely in accord with evidence obtainable elsewhere. So is his inference that the air used in making froth must be finely divided. In October 1912 Mr. Hebbard himself obtained a patent for an apparatus of staggered spitzkasten. Finally, he had the satisfaction of achieving a high extraction, namely, over 90% of the three metals: silver, lead, and zinc. Apart from the record of the steps by which he reached this result, the article is highly interesting as a record of the manner in which froth became recognized as a prime metallurgical agent.

Dull Advertisements

We believe our readers like to read articles based upon unconventional opinions; that is why we publish an occasional contribution sent to use with a 'dare,' such as that on advertising appearing on another page of this issue. However, as we give publicity to the article, we must also disavow anything like an agreement with all the views expressed by our versatile correspondent. We agree with him that a discussion of the subject needs no apology. Advertising is a matter of general interest to our readers, of course; that is what supports our periodical; it is a medium of publicity to the manufacturer of machinery and supplies; the latter finds it an effective medium because it is read by the very people whom he wants to reach, namely, the men who have the say in the purchase of machinery and supplies. By reason of this fact, the editorial department is able to furnish a lot of useful reading matter at a price far below the actual cost. So much for that. Yes, "articles on advertising are intolerably dull," mainly because they are insincere. They appear to be written for the delectation of advertising agents and solicitors instead of being prepared to arouse the interest of the consumer. Undoubtedly the bald statement that an article or machine is the best of its kind and the only pebble on the beach does not impress a thoughtful man. Mere assertions, even if shouted loudly, as by a street-peddler, do not carry conviction. For that reason we wonder sometimes why manufacturers do not give a clear description of their machine in one advertisement, following it, for example, with a letter from the manager of a mine stating that he had found the machine efficient. It is not always easy to get permission to publish such letters, but certainly they are more convincing than the manufacturers' opinion of his own product, and we may suggest that managers should be willing to do this, not as a favor to the manufacturer only but as a service to the public, particularly other managers of mines, to whom the opinion of an independent engineer is of more value than a dozen unsupported claims. As to where and how "the average mining man" first hears of a tool or machine, we venture to suggest that while our nomadic correspondent may get such information by word of mouth, it is not possible for those less migratory to keep in touch with the progress of the art except by reading the technical papers, the particular function of which is to give this kind of information, first, by the advertisement of the maker of the tool or machine and, second, by the record of its use and usefulness in writings describing current technical practice, written by superintendents, engineers, and others able and willing to give disinterested and reliable information on the subject. The "average mining man" may rise very early and remain unusually wide-awake for a period far in excess of union hours without hearing of the successful introduction of a new tool at Dan or a new machine at Beersheba. Yes, "mining men read the advertising pages" of this journal, otherwise it would cease to exist. It may be true—we think it is—that some advertising matter is so trite as to lose in effectiveness. More effort should be made to give information on the particular points that present themselves to the user of a machine; we know that some of our advertisers appreciate this requirement, for they give the data demanded; but, on the whole, we second our correspondent's 'kick' and venture to suggest that it would be well for the manufacturer to keep in mind the kind of man he is aiming to impress—a man as keen as himself. That applies also to the writers of technical papers. It is well to imagine oneself addressing an individual, typical of the class of man whose interest it is expected to awaken. Advertisements, like articles, should be written not for the people whom the sophomore that mixed his Greek and Latin called the 'hoi populoi,' but they should be written, like a letter, to a real thing of flesh and blood, brains and memory. If any of our readers care to send us comments on the advertising pages, we shall be glad to have them, in order to transmit judicious suggestions to our business supporters, the manufacturers that advertise with us. In short, we want to make the paper useful to the maker and to the user of machinery. If we do that, we shall have ample scope for discussing conduct, ethics, and the higher mathematics.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Carat

The Editor:

Sir—I noticed in your issue of March 27, page 488, that you state the weight of a carat as being equal to 3.166 grains. This was the equivalent of the English carat, but an international convention has adopted the metric carat of 200 mg. on account of the diversity of carats previously employed. I understand that the equivalent in Holland was 3 grains, in England 3.166, in France 3.18, and U. S. A. 3.2, but even greater diversity existed in the past and it is now practically impossible to ascertain what was the original weight of many of the historical gems.

The standardizing of the carat was a much-needed reform. The new unit only varies from the older ones by a small percentage, being almost exactly 2.5% more than the Dutch and the same amount less than the English standards, while at the same time it is instantly convertible to the metric system (5 carats = 1 gram). No doubt the abolition of the carat would have been a greater reform, but standardization is the next best thing.

FRANK ROWLEY.

Rosebery, Tasmania, July 10.

[The British standard was 205.304 milligrams or 3.1683 grains, that is, 151½ carats to the ounce troy. It is supposed that the 'carat' was derived from the weight of a hard leguminous seed. The Greek name was *keration* and the Latin *siliqua*. The seed of the locust-bean or *ceratonia siliqua* was found, by L. J. Spencer, to weigh 0.197 grams or 3.04 grains.—EDITOR.]

Efficiency Engineering in Mines

The Editor:

Sir—It is with considerable hesitation that I reply to the letter of R. E. Cranston and W. H. Shockley in the PRESS of August 7. The analysis of efficiency engineering in its effect on miners, with any attempt to generalize, is liable to be not only invidous and insipid, but nonsensical. In the same issue of the PRESS, A. E. Jacobs, of Kalgoorlie, Western Australia, demurs to the practice of comparing operating costs of different mines on the assumption that the factors relating to cost at various properties are standardized. To a still greater degree is there objection to generalize as to what miners are liable to do when efficiency rules are imposed upon them. All workmen, but particularly miners, are 'queer.' They act as much according to unreason as reason; they are suspicious, short-sighted, conservative, unjust, paradoxical, and yet they will work hard and long and cheap for a superintendent who handles them in a way they understand and admire. In a certain mining district in New York state the men worked for years with great satisfaction to all concerned under the supervision of a general manager who appealed to them by what he *didn't* do. When the company changed managers it found no end of trouble. The manager who got the excellent results didn't paternalize, efficiencyize, or any other kind of 'ize, nor did he meddle with prohibition or mushy 'reforms.' What he did was to set the men an example of working and minding his own business, getting results consistently. A certain amount of inarticulate admiration of the 'old man,' particularly as to his know-how ability in times of stress when things looked dark, was not entirely absent among the workers; and sentimental as this consideration may appear, it meant dividends and success to the company. The men would work for the manager they liked, in water, over-time, and with a supreme disregard for discomforts, where they wouldn't work at all for anyone else. Now, under what rule of Taylorism is this case classified?

I can imagine the snort some American mine-superintendents would give if confronted with the custom prevalent among the thousand iron miners on Bell Island, Newfoundland, of stopping work at quarter-shift to boil and drink a 'mug-up' of tea. And I can imagine the thousands of dollars they would undoubtedly lose the company when they attempted to do away with 'mug-up.' Owing to local peculiarities, the character of scattered underground workings, the general contrariness of human nature, and some things impossible to classify, there is usually a certain way of handling any particular community of workmen in which to get the most out of them with a minimum of bad results such as strikes, disorganization, and 'soldiering.'

It is a typically modern fallacy to believe that raising a workman's pay will invariably insure more energy put in the work, better loyalty, and greater efficiency. Sometimes it will; other times it has the opposite effect. It is also a trend of the times, more especially by kind-hearted but muddle-headed busybodies, to suppose that workmen appreciate 'welfare work' and such rot. Naturally, opinions on labor questions are only opinions, since much difference of outlook exists, but it appears to me that any interest miners seem to manifest in the introduction of systems under a bureaucracy, or existing in 'model towns,' is only due to the novelty of the thing.

At one mine in Michigan where attempts at Taylorism were made, the superintendent lost some very able foremen, shift-bosses, and miners, by his activities at 'spying' on the men. He listened over the mine-telephone, appeared underground at 3 o'clock in the morning, and generally sneaked around the place. The men said there was no satisfaction in working for him, and an unprejudiced outsider would probably agree with them.

I remember a mechanic at an exploration in the swamps of Minnesota who went down under hot water in a mine-sump to repair a drowned pump where steam had been leaking but pumping had stopped. He worked in the hot water and mud for hours because the engineer-in-charge called him 'master-mechanic.' There was an excellent miner working at an exploration near Iron River, Michigan, who quit the job because the superintendent told him to shovel instead of drill (practice on the Michigan iron ranges is to have the trammers do the shoveling, unlike the Mesabi custom where miners do their own shoveling). These are examples of queer twists in the point-of-view of miners; the two cases are exceptions, but queer twists of one kind or another are not exceptions.

I believe miners give best results over a long period of time when they are left alone. They like personality in a superintendent; they do not like bureaucracies, officiousness, flub-dub, welfare, nor Taylorism.

P. B. McDonald.

Boston, August 14.

Wet Method of Mercury Extraction

The Editor:

Sir—I have read Mr. Thornhill's interesting article in your esteemed journal of June 5 in which he refers to some experimental work in the wet treatment of mercury ores described by me in the *Australian Mining Standard* of June 8, 1911. As far as Australia is concerned, Mr. Thornhill is right in saying that the method there described has not been taken up or tried on a commercial scale. In his article he gives certain chemical formulae that might possibly be assumed to have been contained in my original paper. None, however, were given, hence I ask the favor of a little of your space to supplement Mr. Thornhill's formulae descriptive of my method with those that I conceive to be more representative, perhaps, of the method mentioned.

I may premise that HgS in going into solutions, under the circumstances considered, forms a thiosalt with the alkali metal, so that instead of a mercuric cation and a sulphide anion, there is formed HgS_2—mercuric disulphanion—with disodium cation $Na_2.HgS_2''$— soluble in certain conditions of concentration, but hydrolyzed on dilution with water into NaSH, HgS, and NaOH. This is an important point in working the method, a proper concentration of sodium sulphide and alkaline hydrate being necessary to the complete dissolution of HgS: the reaction outlined may be thus represented:

(1) $2Na_2S + HgS + H_2O \leftrightharpoons Na_2HgS_2 + NaSH + NaOH$

Under varying conditions of dilution and temperature the reaction is reversible; hence the necessity for carefully determining these points by actual tests on the ore to be treated.

Assuming that these conditions have been settled, the rest of the process is as follows: Zinc hydrate is added to completely decompose the mercury thiosalt and the excess of sodium sulphide thus:

(2) $Na_2HgS_2 + Na_2S + 2Zn(OH)_2 = HgS + 2ZnS + 4NaOH$

If now the precipitate of mixed sulphides be acted upon by H_2SO_4 or HCl, the latter preferably, if we are going to regenerate the $Zn(OH)_2$ cheaply, we produce H_2S, which can be passed into the NaOH solution in (2) partly regenerating solvent. Some mechanical loss is inevitable. These two reactions may be written thus:

(3) $HgS + 2ZnS + \begin{cases} 2H_2SO_4 \\ 4HCl \end{cases} = HgS + 2Zn \begin{cases} SO_4 \\ Cl_2 \end{cases} + 2H_2S$

(4) $2H_2S + 4NaOH = 2Na_2S + 4H_2O$

If metallic zinc be added to equation (3), mercury is reduced, an extra molecule of acid being needed and an extra molecule of H_2S liberated.

(5) $HgS + Zn + 2HCl = Hg + ZnCl_2 + H_2S$

Zinc hydrate may be regenerated from $ZnCl_2$ by milk of lime, thus:

$$ZnCl_2 + Ca(OH)_2 = Zn(OH)_2 + CaCl_2$$

This is perhaps better than the method suggested in the paper quoted, which proposed using the alkaline solvent solution to regenerate $Zn(OH)_2$. In operating the process as just described, there will therefore be an excess of $Zn(OH)_2$ and H_2S and a loss of HCl, should it be desired to reduce the HgS by the method proposed instead of distilling HgS at stage (3) as proposed in the original paper.

Charles A. Mulholland.

Sydney, Australia, July 21.

The waters of mineral springs have usually been studied by chemical analysis alone. Jacques Bardet, a French scientist, thinking that spectroscopic analysis would enable him to find traces of metals that had escaped analytical chemists has examined the waters of 54 springs from 34 health-resorts in France. He found that the waters always contained lead, that silver and tin were usually present, and that molybdenum and copper were frequent. He also found bismuth, zinc, and glucinium, and two metals that are considered extremely rare, namely, germanium and gallium. He also detected, but less commonly, antimony, cobalt, chromium, mercury, nickel, gold, thallium, titanium, vanadium, and tungsten. These results may account for the healing power of various mineral springs and may form a basis for theories of ore deposition. They certainly prove that some rare metals are more widely spread than has hitherto been supposed.

Flotation at the Central Mine, Broken Hill

By JAMES HEBBARD*

†Early Attempts at Frothing. While concentrating the galena in the lead ore produced from the Central mine, a valuable by-product was obtained in the form of slime assaying 18% lead, 20% zinc, and 16 oz. silver per ton. This came from an ore in which quartz and rhodonite were the chief gangue-minerals. In the course of ordinary operations, it had long been observed that a froth was formed containing high metallic values, in silver and lead particularly, whenever conditions were favorable, as, for instance, where the rotation of trommels, or the splash of the elevators or raff-wheels, or the motion of the jig-plungers, produced a violent agitation of the mill-water containing slime. Early in 1901 a series of experiments was carried out for the purpose of reproducing and accentuating the conditions responsible for this valuable float-concentrate. Experiments and tests, extending over several months, were made on slimes of varying degrees of fineness. Among the appliances tried was a series of funnel-shaped vessels with the small ends downward, each fitted with an overflow-lip. The bottom end of the funnel or cone-shaped vessel was fitted with a tap or plug discharging the contents into the next vessel in the series, and so on. To each vessel was attached, near the bottom, a water-pipe, as well as a pipe carrying compressed air. The object of the water was to provide an upward current for the contents of the vessel, while the object of the compressed air was to produce agitation, and enhance the agitation effect of the up-current of water, in the expectation of reproducing the conditions causing the 'float' or metallic froth. Speaking generally, these experiments were on the lines of a spitzkasten, with a strong up-current to produce an agitation of the slime-water, assisted by jets of compressed air. It was thus early recognized that the bubbles of froth noticed in the wet-concentration operations were due to the aeration produced by violent agitation, resulting from mechanical implements moving rapidly in water. In these experiments a metallic froth or scum could be produced and recovered assaying 26 oz. silver, 30% lead, and 22% zinc. The appliance employed is illustrated in Fig. 1.

[Up to that time the lead concentrate was the only marketable product from the ordinary water concentration. Besides calcite, the ore contained a good deal of rhodonite and garnet, each of which has a specific gravity close to that of blende. Thus water concentration could only yield a quartz tailing and a leady zinc-rhodonite-garnet middling.]

†Abstract of paper appearing in the Proceedings of the Australasian Institute of Mining Engineers, November 10, 1913.

*Manager of the Central Mine, Broken Hill, New South Wales.

Preliminary Tests. Early in 1903 an exhaustive series of laboratory tests was made on the lead by-product by flotation methods, using heated sulphuric acid and salt-cake solution. These tests yielded some slight measure of success on material specially prepared, that is, on grainy material from which both the coarse and fine had been eliminated, leaving it evenly sized. Certain classes of the material produced by our mills contained such a large proportion of carbonates—such as carbonates of manganese, lime, and lead—that no flotation could be secured except by a prohibitive consumption of acid. These tests were carefully made, but

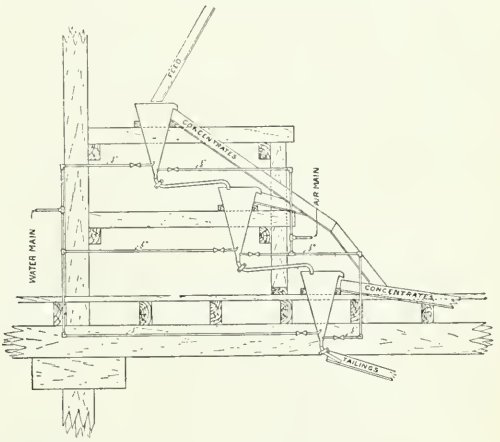


Fig. 1.

the best work done in the laboratory was not equal to that being secured on a commercial scale in the existing magnetic plant. The tests on these flotation methods were conducted in pans or vessels worked on the principles of spitzkasten, following the lines of Potter and Delprat. The first apparatus was constructed so that the liquors could be raised in temperature by the application of direct heat underneath the pan; but in the later types the temperature of the liquor in the pan or spitz-box was maintained by the injection of live steam into the storage-tank. In none of these tests was agitation employed, the material to be treated being fed practically dry on the surface of the liquor in a regular stream, and the heated liquor added through a pipe discharging near the bottom of the vessel, and given an upward inclination in order to produce an up-current in the box itself and a gentle overflow at the lip. A still surface was imperative in this operation, and it was equally evident that the operation depended largely for

its success on surface tension of the liquor, after the gas evolved by the action of the acid on the mineral carbonates had raised the particles. This surface tension was increased by the density attained in the one case by the salts formed from the mineral and gangue through the action of the sulphuric acid, and in the other by the addition of salt-cake. In all these experiments the liquor was returned by the ordinary type of air-lift, using compressed air at about 70-lb. pressure. These experiments definitely demonstrated:

1. That there was a limit to the size of the particle that could be buoyed up.

2. That any material below a certain size, no matter what its character—whether gangue or mineral—floated, owing to the density of the solution.

3. That if the finer particles of gangue were not eliminated before treatment they would be floated with the mineral, and lower its value in metals to such an extent as to make it unmarketable.

Slime, whether existing as a by-product of the ordinary wet-mill concentration or subsequently produced in preparing tailing for treatment, bulked so largely among the total material available for re-treatment that any process that failed in this direction was too limited in its scope to be of much value to the Central mine.

As far as any process up to date was concerned, slime had to be regarded as of no value except in so far as it was available for smelting. The Broken Hill Proprietary Co. had used a considerable quantity in this way, and had discovered that roasting or sintering the slime in open heaps after briquetting gave a fair product valuable for smelting, a good deal of the sulphur and a fair proportion of the zinc having been driven off. The Sulphide Corporation also sought to make its slime available by this means, but it was proved that the losses of metal were too great to justify this method of rendering the slime amenable to direct smelting.

Cattermole or Granulation Process. The foregoing experiments were abandoned on account of information received from London. C. F. Courtney, who was in England during the year 1902, advised that a discovery of considerable importance had been made; that laboratory trials gave every indication of success on a large scale; and that the process was so comprehensive as to include the finest slime and varying coarser sizes of particles up to ½ mm. diam. This was subsequently known as the Cattermole or granulation process, and consisted in the agitation of a mixture of pulp, oil, and water, containing a suitable acid, or an alkali with soap or other emulsifying agent, so as to agglomerate the oil-coated particles into granules. The oil was thus employed in a state of emulsion in water in the presence of an emulsifying agent, such as soap. After agitation the mixture was passed into an up-current separator or classifier to remove the lighter non-oil-coated particles from the agglomerated masses of oil-coated particles. The lighter sand having been eliminated, the pulp passed to a second series of agitators to increase the size of the granules, and thence to a second classifier for the removal of the heavy sand. From the bottom of this second classifier some granulated concentrate was recovered, but the heavy sand from the overflow also carried over, with the up-current, a large amount of granulated mineral. This mixture of granulated mineral and heavy sand passed then to a third series of agitators, and thence to a shaking table, where the granulated mineral, rendered more buoyant by directing jets of compressed air onto the surface of the moist pulp, was buoyed to the surface of the water and floated off the bottom of the table, while the gangue sank and was delivered over the end of the table.

In order to give this process a thorough trial, a model plant was sent from England and erected on the mine early in 1904. G. A. Chapman was specially appointed to conduct experiments with this plant, and started a long series of tests early in June of the same year. It was quickly demonstrated that the process was capable of making high recoveries of all the three metals from the very finest slime, whether taken from the current work of the mill or from old accumulations, and also that old tailing or new crude ore were amenable to treatment when crushed to a given fineness. The largest size of particle that could be recovered was ascertained to be about ½ mm., thus confirming the London work; but it was found that results improved with a decrease in size to impalpability.

In the early tests by Mr. Chapman, emulsions of the heavy oil of petroleum were used, but the cost was excessive, and it was found impossible to treat slime successfully. Emulsions of fatty acids, and also soft soap, were then tried, but proved prohibitive as to cost, except in the case of oleic acid. Oleic acid emulsion was found to act rapidly and effectively on crude ore as well as on all lead by-products, including slime.

Mr. Chapman's work on oils and the results obtained by him with the model plant using the granulation process were satisfactory, but it was thought wise to have these confirmed by an independent chemist, and therefore J. C. Moulden, the company's chief metallurgist at Cockle Creek, was called in, repeated the experiments, and amply confirmed Mr. Chapman's work. Later it was found possible also to reduce the quantity of oleic acid, as was proved by the following tests in December 1904:

Material used was crushed tailing mixed with slime.

Test No. 1. 3.5% oleic acid on mineral and 0.75% sulphuric acid circuit.

The cost of emulsion in this case was 10s. per ton of ore, but the results were excellent, the concentrate being recovered as partly granulated and partly float or froth.

In test No. 2, only 0.75% of oleic acid with the same (0.75%) sulphuric acid circuit, in which case the cost of emulsion amounted to 2s.3d. per ton of ore, the results being excellent, with all float concentrate, no granular material being formed. This test took considerably longer in agitation.

Erection of Large Plant. Mr. Chapman's tests, and their confirmation by Mr. Moulden, established the fact that a process was obtained that would, with suitable arrangements for crushing, efficiently handle the whole of the by-products of the wet mill, including slime. It

was accordingly decided to erect a plant on the lines of the model, with slight modifications as dictated by experience, capable of treating 100 tons per day, operating on a commercial scale.

It was clear, from experiments and observations, that the time of agitation was a factor in the aeration and oiling of the mineral particles. Therefore, reckoning from the size and capacity of the mixers in the model plant, a mixer was built of the following dimensions: 5

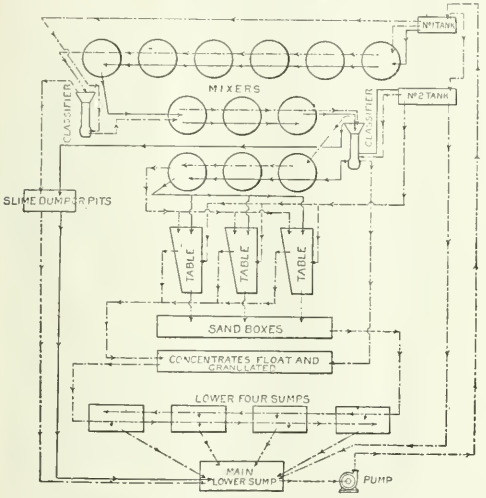

FIG. 2.

ft. deep and 3 ft. diam., with a wooden stirrer 2 ft. 6 in. diam. at bottom placed vertically and made to revolve at the rate of 350 r.p.m.

Experiments with this one mixer unit indicated that, to make the treatment continuous for the stipulated 100 tons per day, it would be necessary to have for the first unit a series of six mixers in order to allow of the proper cleaning of the particles and the thorough aeration of the whole mixture before the discharge of the material under treatment from the last of the series. The mixer was of the core-stirrer type.

Accordingly, the plant was designed on these lines, and consisted of:

1. Grinding apparatus.
2. Vat for emulsifying various oils.
3. Set of six mixers in series.
4. Upcasts for separating sand and float.
5. Second set of mixers for further aeration.
6. Upcasts for further separation of sand and float.
7. Third set of mixers for re-aeration.
8. Wilfley tables for the separation of coarse sand from granulated sulphide.

Early in 1905 the construction of this plant was commenced; it was completed at a cost of £11,000, and started work in July 1905. The method of treatment adopted was on the lines of the tests made in the experimental model plant, and may be briefly described. See Fig. 2.

The ore, reduced to a suitable fineness, was elevated to a hopper at the top of the building and fed into No. 1 mixer, where it was agitated with the solution, the emulsion (previously prepared on the bottom floor) being added at the same time, together with further sulphuric acid, if required. The feed of ground material and the addition of the circuit-liquor and reagents was maintained constantly and regularly. After passing through the first set of six mixers a pulp consisting of ground ore, acidulated water, and emulsion was passed to a hydraulic-sizing appliance known as an upcast, where the slime-gangue was eliminated by overflowing. The balance of the mixture was passed into the second set of mixers, beginning with No. 7, where more emulsion and sulphuric acid were added if necessary. The agitation and aeration were maintained and the pulp discharged from No. 9 into another upcast, where further slime-gangue was eliminated by overflow. The balance of the material was then passed to No. 10 mixer, and thence through No. 12 to the Wilfley tables. The separation on the tables was effected thus: Such concentrate as had been frothed by the aeration and agitation passed off the table immediately opposite the point of feeding. The granulated or 'air-bally' material remained in close contact with the table, along with the sand, but floated immediately under the influence of puffs of air (supplied through a pipe laid lengthwise and close to the table), and then floated off with the froth concentrate. The sand was delivered toward and at the end of the table, thus exactly reversing the relative positions of concentrate and tailing as ordinarily obtained if working by gravity concentration. The slime and sand were collected in one receptacle and the float and granulated concentrate in another, the surplus liquors in each case flowing to a common sump for re-use.

From the first day of operation the ease with which

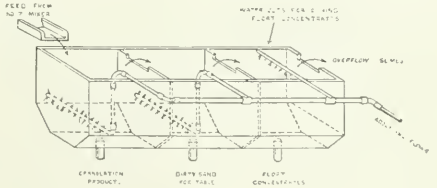

FIG. 3.

the float concentrate could be recovered was very striking; but the separation of the granulated concentrate from the coarse sand by tabling on a large scale was found to be a very delicate and difficult operation, and it was at once evident that 'spitz' separation would relieve the tables. The upcasts were also continually choking and proving a source of trouble, besides sending over large quantities of slime with the concentrate, thus reducing the grade of the product and lessening its market-value.

It was therefore decided, when the plant had been running for a few days only, to construct a small rectangular spitz-box for trial. This was introduced early in

August 1905, the feed to the spitz-box being prepared pulp discharged from No. 7 mixer.

It was found also, as soon as the plant started regular treatment, that the agitation was excessive, and mixers 10, 11, and 12 were cut out.

Cone-agitators made of phosphor bronze were tried, then centrifugal stirrers, but the scour both on the stirrer and the sides of the mixer, due to the impact of the sand, was so great that these had to be abandoned, although the agitation and aeration had been considerably increased.

The spitz-box in the slime-overflow circuit gave excellent results, and toward the end of August it was possible to obtain the requisite agitation by using the first six mixers only. A fresh spitz-box was placed in the position formerly occupied by vats 7 and 8, with arrangements for all tailing-flows, both slimes and sands, to deliver to No. 1 hutch of a special spitz on the floor beneath. The object of this spitz (3-compartment) was (1) to allow a settlement of the granulated material in the first compartment; (2) to effect a settlement of middling for re-treatment on tables in the second; (3) to provide for the deposition of clean sand and slime in the third, with an unrestricted overflow for the float material. Sprays on the surface of the liquor, and upcasting jets of water, were provided to assist the operation. Various simplified forms were later adopted as the process merged from partial to complete flotation, as illustrated in the experimental spitz-box for the granulation plant (Fig. 3).

At first the sand was ejected by sluicing out to a dam; but this being wasteful of circuit-liquor, and therefore also acid, it was decided to construct sand-boxes, through which, in turn, the suspended sand could be deposited—the liquor overflowing from these sand-boxes to be run to the pump-sump and thence re-circulated through the plant. By this means a closed circuit would be secured, and liquor-losses minimized. It was not until November that these sand-boxes were actually in use. Meantime, it was noted, particularly in slime-tests, that the operation was appreciably assisted by raising the temperature of the liquor. Steam jets were, therefore, introduced into the mixers in the plant early in September 1905.

Before advancing further with the evolution of the process as developed in the first large plant, it is perhaps advisable to refer here to certain experiments that mark a most important era in the history of the process.

Discovery of the Frothing Process. We now come to a stage when a remarkable development in the operation was discovered (strangely enough, at the same time both here and in the Patent Co.'s* laboratory in London), which had for its main principle the reversal of all previous operations, and consisted in the complete flotation of each particle of mineral independently in place of granulating the mineral particles and causing them to sink, thus not only revolutionizing the process, but greatly simplifying and cheapening it. The developments noted were mainly along the line of decreased consumption of oleic acid or oil, for example, from 3% oleic on ore, resulting in very little float, down to 1%, giving practically a complete float.

The following data from a report furnished by A. H. Higgins (March 16, 1905), indicate in more detail the nature of the experiments and the effect on the separation produced by varying the percentage of oleic acid:

Details of Experiments

Acid, %	Oleic, c.c.	Percentage of oleic on ore.	Time for aeration, min.	Temperature, C.	Remarks.
1.1	15	3.0	4	30.5°	Very little float
1.1	7.5	1.5	4½	31.0°	Rather more float
1.1	5.2	1.04	6	31.0°	Still more float
1.1	3.1	0.62	6	32.0°	Still more float
1.1	1.66	0.32	7	31.0°	Float vastly increased
1.1	0.5	0.10	8	31.0°	Float vastly increased

In every case the oleic acid has been measured in cubic centimetres and the percentages calculated as though they weighed grains; but, as the specific gravity of oleic is less than that of water (taken as 1), all percentages will be lower than those actually given.

The foregoing obviously proved that the reduction in the percentage of oleic acid materially altered the type or character of the oiling of the mineral particles—the higher percentage producing granules, which were precipitated, while the lower percentages produced a mineral froth. As the quantity of oleic acid decreased, the time required for oiling the mineral particles and aerating them was found to increase, and more froth formed. These tests, followed by many others, led to Messrs. Sulman, Picard, and Ballot's British patent of April 12, 1905, under which "finely powdered ore, suspended in acidified water, is mixed with a small proportion of an oily substance such as oleic acid, amounting to a fraction of 1% on the ore, and agitated until the oil-coated minerals form into a froth, which can be separated from the gangue by flotation. Heat may be applied to facilitate oiling, and either shaking tables or spitz-boxes may be used to separate the frothy mineral from the sands and the gangue slime."

To return now to the record of operations at the large plant, some successful tests were carried out in September, 1905, on dump-slime, by using this flotation method. Agitation was completed in six mixers (using cones) in 0.6 to 1% sulphuric acid at a temperature from 80-90° F. The quantity of oleic acid used in these tests was from 0.15 to 0.2% on the actual dry weight of slime treated. From the sixth mixer the pulp passed "with a good splash" to the first spitz, and the residues from this "with a good splash" to No. 2 spitz, and the tailing from this latter spitz-box was run into dams. These and other experiments emphasized the importance of dropping the pulp vertically into the spitz to assist aeration and subsequent flotation, and of heating the liquor to enhance the oiling of mineral particles.

The three-compartment spitz-box with upeast water-flows gave place, in turn, to a two compartment spitz-box without upeast flow, and this, in turn, was replaced

*[Minerals Separation Ltd.—Editor.]

by a single-compartment spitz, the latter being provided with a rigid flat board on which the feed was splashed to assist aeration. Conical spitz-boxes were tried, but not generally adopted.

From Granulation to Flotation. The plant had now been running for a couple of months on tailings and slimes from various sources, and during this time the frothing method was generally ousting the granulation process, until, finally, the superiority of the spitz-box and froth method was clearly demonstrated. The Wilfley tables of the original plant were then dismantled to make room for the sand-boxes already mentioned, and the granulation gave way to flotation with simple spitz-boxes early in October, after treatment of approximately 1700 tons of crude ore, tailing, and slime.

This method of working, thus briefly outlined, quickly established itself as capable of dealing with the company's ores and by-products, and Mr. Chapman's patent of September 1906 was taken out to protect the various discoveries made by supplementing Sulman, Picard, and Ballot's patent (No. 5032, 1905). Under Mr. Chapman's patent:

1. The ore, suitably crushed, is agitated with acidified water in the first mixer and heated.

2. Oleic acid is subsequently added in the second vessel.

3. The pulp is maintained at the desired temperature in third and following mixers, with violent agitation in each mixer to insure complete and thorough aeration.

A sequence of operations is thus arranged by which the solution, after the second agitator, is practically or entirely neutralized, so that the liquor in circuit as a whole is neutral, except at outset, when the ore is introduced.

The adoption of this flotation process with its neutral liquor allowed the use of iron parts where formerly, under the granulation method, with acid liquor, only wood or special metal could be used. For instance, the original wooden-cone mixers, which had been replaced by centrifugal stirrers of copper or beaters of regulus metal, were now replaced by four-armed stirrers of cast-iron.

A great difficulty lay in the grinding. The experiments had proved that the best work could be obtained on material that would pass through 40-mesh, and that practically the finer the material the better the recovery. The whole experience in the fine grinding had been with ball-mills in our magnetic plant, and accordingly a No. 8 Krupp dry ball-mill was attached to this plant as part of the equipment. The dry mill proved unsuitable, and, with considerable difficulty, it was converted to a wet mill. Even then its capacity, allowing for numerous break-downs partly due to forcing its capacity, was too limited, and two No. 5 Krupp wet ball-mills were installed to assist. Meantime, experiments proved conclusively that grinding-pans were superior in character of work, cost of maintenance, and power consumed, to the ball-mills for re-grinding tailing, whereupon we installed a grinding-plant which was gradually increased until the ball-mills were thrown out of use entirely. The character of the work was much improved, and it was then evident how much the progress of the process to a satisfactory stage of efficiency had been retarded by lack of efficient grinding appliances.

Extension of Plant. The operations of the first plant were commercially and technically successful, and an extension was completed, with all its appurtenances, including grinding-pans for the reduction of the material to the requisite degree of comminution, conveyor-belts for the disposal of the residues, together with bins for concentrates and tanks for storage of liquor, toward the end of 1906, at a cost of £25,000, the sum of £11,000 having been already spent on the initial experimental plant. The total quantity of material treated by this flotation plant was 135,808 tons, which yielded 45,147 tons of high-grade zinc concentrate. The plant continued in successful operation until the completion of the wet-mill zinc section, which was capable of supplying the quantity of zinc concentrate under contract. During the time this plant was in operation numerous tests were made with a view to increasing the aeration, which was recognized as the chief factor in flotation, and at the same time lessening the mechanical energy absorbed in aerating. Among these may be mentioned

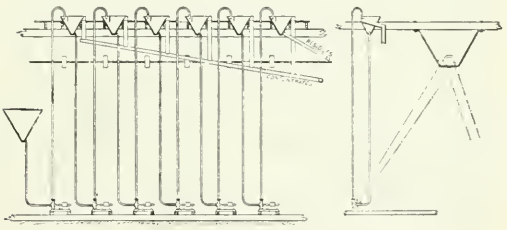

Fig. 4.

the nest of centrifugal pumps, as illustrated in Fig. 4. The pumps were worked in series, each one drawing a tailing from the preceding spitz and discharging into the next succeeding spitz. The aeration and flotation was produced satisfactorily, but it was soon found that the scour in the pumps, caused by the gritty nature of the material being pumped, was so great that the heavy maintenance would counteract the other advantages. Another expedient was to lift the whole of the tailing discharged from the first spitz by means of an air-lift. This also resulted in increased aeration, but it was found that the volume of liquor would have to be increased to an impracticable quantity to give the necessary velocity to carry the particles of ore, etc., up the rising leg of the pipe and prevent settling. An elevator was subsequently installed in its place to command the third spitz of the series. Further expedients were the insertion of a jet of air into a centrifugal pump used for raising liquors and material for re-treatment, the introduction of a jet of compressed air into the mixer boxes, and also the insertion of pipes in the mixer-boxes in such a position that air would be drawn into the bottom of the mixer by the rotation of the blades. As a result of

all these expedients, the conclusion was formed that the air, to be of value, must be finely comminuted, but that any addition was of value that would decrease the energy required to secure aeration by means of mechanical agitation.

Minerals Separation Plant. The Minerals Separation company, owners of the froth patents, purchased the tailing-dumps on the Central mine, and, by arrangement, a plant was designed and erected by the Sulphide Corporation for their treatment. The plant is shown in cross-section in Fig. 5, and was designed on previous experience for the treatment of 2000 tons per week. It was finished at a cost of £26,000 complete. The efficiency of the grinding-pans proved so great with the new design of positive pan that the plant was able easily to handle 5000 tons per week. This plant was responsible for the treatment of 709,999 tons of tailing, etc., and the production of 242,462 tons of concentrate up to the time it was shut-down in June, 1911, on the exhaustion of the dumps.

In connection with the Minerals Separation plant, it is important to note that the fact of the circuit being no longer acid, but neutral, has been taken advantage of, inasmuch as there is only one circuit through iron grinding-pans, agitators, and spitz-boxes. The original granulation plant, being designed for acid circuit, was equipped originally with wood throughout where liquor circulated, and with dry-crushing ball-mills for the same reason. Later, wet crushing was adopted, but with a fresh-water circuit, kept carefully separate from the acid circuit in which the actual separation took place. The successful development of the flotation process, however, has enabled both crushing and separation to be conducted in one and the same circuit, and has thus greatly simplified operations.

The liquor that was circulated through the Minerals Separation plant was approximately 25,000 gallons per hour. During the course of operation, therefore, over 600,000,000 gal.—equal to nearly 3,000,000 tons—has passed through the 12 iron grinding-pans of this plant without detrimental effect. No stronger evidence could be produced as to the freedom of the circuit-liquor from acidity. The maintenance charges on these iron pans are no heavier than corresponding charges on exactly similar grinding-pans in the lead-mill crusher-section, where fresh water only is used.

Following exhaustive experiments in the laboratory, various media have from time to time been used for long periods on the commercial scale, both in substitution for and in combination with oleic acid. Chief among such media are amyl alcohol, resin-oil, camphor-oil, pine-oil, and eucalyptus, with all of which ingredients good work has been obtained. Thus Nature, in close proximity to the vast bodies of complex ore, has provided the means for the concentration of such ores, for the essential oil of the Australian eucalyptus is one of the best-known media available for the successful exploitation of refractory Australian ores. It is of interest to note here that this application of an Australian product to the treatment of complex ores is the outcome of a research on the Central mine by an Australian metallurgist, Henry Lavers; and it was also in the milling-plant on the Central mine that eucalyptus oil was first used on a commercial scale for concentration by flotation.

This satisfactory stage having been reached, attention could now be turned to improvements in methods of handling, and, on suggestions from the owners of the patents, it was found that, by connecting the bottom of each spitz-box with the bottom of the next mixer in series, that all the spitz-boxes could be kept on one floor, thus improving the supervision of the work. An experimental plant of this nature was erected at the end of our No. 2 zinc section in September 1910, and, proving highly successful, the system was altered with confidence to this method of working. Experience shows that, for

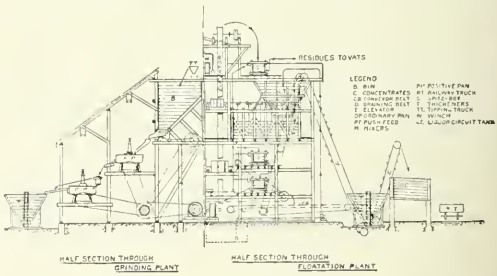

Fig. 5.

ideal work, the feed material should all pass through 40-mesh, but it is impossible to secure this condition of grinding at all times in the mill, as designed. Moreover, although the Sulphide Corporation was quite aware that improvements in character of plant and methods of operation generally were easily possible, their attention, by force of circumstances, had to be turned sedulously to increasing the production with the appliances at hand. As illustrating what the writer means by ideal grinding, the records of the average assays of residues show continually that where the average in zinc is from 2 to 2.5%, that portion remaining on 40-mesh will assay from 3 to 4% zinc. As illustrating the character of feed, and proving that the process is capable of handling successfully the very finest material, sizing-analyses by commercial screens of the feed to the zinc-section, zinc-concentrate as shipped, and de-leading plant lead-concentrate as shipped, are given:

Feed to zinc section.			Zinc concentrate.			De-leading lead.		
Through	On	%	Through	On	%	Through	On	%
	40	11.2		40	1.5		40	1.9
40	60	21.4	40	60	16.9	40	60	7.5
60	80	19.4	60	80	21.1	60	80	15.8
80	130	15.6	80	130	21.7	80	130	18.8
130	180	7.3	130	180	7.4	130	180	8.5
180		25.0	180		31.4	180		47.5

Results Obtained. For comparison with the work of the old mill, the following summary of results achieved by the existing plant will be of interest. This table

summarizes work done on a commercial scale in the Central mill over a period of twelve months, ending December 28, 1912, and demonstrates conclusively the vast improvement in concentration practice made possible by the adoption of the flotation process.

SUMMARY

	Prop.,	Assay value. Ag,	Pb,	Zn,	Recoveries. Ag,	Pb,	Zn,
	%	oz.	%	%	%	%	%
Lead concentrate ex lead section	16.0	33.1	67.0	6.7	44.7	72.4	6.1
Lead concentrate ex de-lead plant	1.4	50.9	62.5	12.5	5.9	5.8	1.0
Total lead concentrate	17.4	34.5	66.7	7.1	50.6	78.2	7.1
Zinc concentrate	32.7	16.1	8.1	46.4	42.1	15.9	84.7
Total concentrates	50.1	...	...	...	92.7	94.1	91.8

Modifications of the wet mill are now in hand for the improvement of the grinding, but it is felt that, as the proportion of lower-level ore increases, the grinding appliances will have to be increased in order to allow for the finer crystallization of the minerals in the ore as further depth is attained. The writer is of opinion that the figures quoted clearly show that if the ideal grinding is obtained the already high recoveries of metals will be further augmented.

It is unique in the history of concentration that so far-reaching and extensive a development should have reached its present state of perfection in so short a space of time, and more wonderful still that it should prove applicable in an equally masterly manner to so many other classes of ore. There can be little doubt left in the minds of those who have seen this new system of concentration that it must of necessity spread to all parts of the world.

SCIENTIFIC MANAGEMENT of the Watertown Arsenal saved $240,461 in one year. The saving on surplus stock alone amounted to $122,789 and there still remained an unnecessary surplus of $130,313. As a rule, too many supplies are carried. The manager of one of the best known and best managed concerns in the United States found that he had tied up in his store-rooms the equivalent of a year's output. By systematizing he carries only one-third of the year's business in stores, while the output has increased 50%. In another plant 3000 varieties of lace have been reduced to 300. A small printing plant with 200 items of stores found that 85 of these were superfluous. Seventy-six styles of pens were used in one Government department.

ASBESTOS. The total tonnage quarried in the Province of Quebec for 1914 was 2,127,395 tons. From this, $3,053,530 of asbestos was extracted, which make the average yield per ton of the rock $1.44. In 1913, this average was $1.45; in 1912, it was $1.38, and in 1911, it was $1.53. These figures have to cover all expenses of quarrying, milling, grading, and sacking of the asbestos, and profits. Last year the industry gave work to 3054 men, who received $1,285,697 in wages and salaries.

Increasing Spelter Production

With an ultimate capacity in view of 660,000 tons of spelter annually, the increases now being effected in the zinc smelters of the United States will not only have brought into being a number of entirely new plants, but will have rehabilitated smelters that had been entirely dismantled. The most important developments along this line will be the completion before the end of the current year of two smelters by the United States Steel Corporation. Its effect will be to remove from the open market the largest individual consumer of spelter in this country. The following tabulation is compiled showing where the bulk of the new production will come from:

Plant and location.	New retorts.	Increase, tons.
Hegeler Zinc Co., Danville, Ill.	1,800	7,200
Matthiessen Zinc Co., La Salle, Ill.	912	3,648
Prime Western Spelter Co., Iola, Kan.	2,600	10,400
Kirk Gas & Spelter Co., Iola, Kan.	2,800	11,200
Am. Z. L. & S. Co., Caney & Deering, Kan.	4,800	19,200
E. V. Lanyor, Pittsburg, Kan.	1,150	4,600
Cherokee Spelter Co., Bovee, Kan.	1,200	4,800
Pittsburg Zinc Co., Pittsburg, Kan.	530	2,120
Chanute Zinc Co., Chanute, Kan.	400	1,600
Nevada Zinc Co., Nevada, Mo.	1,200	4,800
George Nicholson, Dervar, Okla.	3,000	12,000
Am. Zinc & Chemical Co., Langloth, Pa.	2,680	10,700
U. S. Steel, Gary, Ind.	3,480	13,840
U. S. Steel, Donora, Pa.	7,640	30,560
National Zinc Co., Bartlesville, Okla.	1,200	4,800
U. S. Zinc Co., Pueblo, Colo.	400	1,600
Total new capacity	35,772	143,008
Extant January 1, 1915	119,606	478,424
Total capacity by end of 1915	155,378	621,512

The American Zinc & Chemical Co. started operations last year, its initial capacity being 864 retorts. The American Metal Co. controls this company. In addition to the increases noted above, the New Jersey Zinc Co., operating both east and west, has, it is understood, enlarged its capacity. A few months ago it was believed to have in operation a total of 21,992 retorts capable of producing about 55,000 tons of spelter. It has planned for $650,000 expenditure in New Jersey. The United States Smelting, Refining & Mining Co. will soon be a factor in spelter, the company having purchased some old plants now in the course of rehabilitation.—*Boston News Bureau.*

PROSPECTORS desirous of Government assistance should emigrate to Australia, where they have a chance, at least, of being helped instead of ignored. Up to the end of 1912 New South Wales had assisted prospectors to the tune of over $2,000,000, of which $60,000 was paid in 1912. Smaller amounts have been given by the other Australian States.

TRIPHOSPHATE OF CALCIUM added to the food of poultry in the proportion of 1 to 100 causes an increase of 27 to 31 per 1000 in the number of eggs laid. As this chemical sells for a comparatively low price there is no reason why it should not be adopted.

Dull Advertisements

By P. B. McDONALD

An article on advertising almost needs an apology. Not because mining men of all sorts are not keenly interested in advertising and advertisements—for the exact reverse is true—but because nearly all articles on advertising are intolerably dull. Full of statements that no one believes, and composed of arguments that everyone is tired of seeing, most "talks about advertising" are not worth reading—and are not read. For instance, it is constantly being said that "advertisements necessarily insure merit in the goods, because expensive advertising could not be continued unless the product were a solid one." It is, however, evident to nearly everyone that a very mediocre and indifferent article could be foisted upon a gullible public for years through advertising by a concern that shaped means to an end. For, that very thing has been, and is being, done constantly both in the United States and Canada. Proving that an article is a "solid one," moreover, is not the aim of advertising in a technical journal.

What a mining man wants to ascertain from an advertisement is whether or not a new tool or machine will serve to do his class of work. He is not helped by such broad claims as assert that the machine in question will do everything everywhere, as some advertisements do. A superintendent, engineer, or mine foreman wants to learn not what a "world-beater" in general a particular machine is, for he knows full well that no one machine or tool is adapted for everything, but he would like to learn just what class of work it was aimed to accomplish and to what it is suited.

It is solemnly proclaimed in a recent discussion of advertising that the average mining man "first hears of new equipment and tools through the advertising page," which is nonsense. Almost invariably he has heard of it in half a dozen other ways before the manufacturer gets around to advertise it. For the average mining man is rather more alert to pick up information on deserving new equipment than the manufacturer is to advertise it, since, if the machine is a success, the demand for it at first is likely to exceed the rate of manufacture. Furthermore, although the case may happen occasionally, it is somewhat of an insinuation against a mining man's possession of brains to assert that he has been so sleepy as not to hear or read of a deserving new machine until he sees it in an advertisement. Mining men are not quite so dull-witted as some advertising-managers.

Mining men read the advertising pages a good deal. They would read them a good deal more than they do if manufacturers would change their advertisements from the sameness that makes them trite, and if they would recognize that the readers are intelligent enough to appreciate as much of interest in the advertising pages as in the journal proper. This does not apply to standard old products that never change and are not supposed to change, and which are so simple in character as to be perfectly understood by everyone. But it applies to most of the equipment advertised in technical journals.

Strange to relate, very little information that is of any value is conveyed by advertisements, and that which *is* stated is frequently befogged in trivialities. If a mine superintendent wants to really learn about a new machine of which he has heard, he can get very little information as a rule from an advertisement of it. For instance, an advertisement will show a picture of the machine with the general information underneath that it "will suit your requirements," or "gives satisfaction" or "economy guaranteed." What the superintendent wants to known is its special field, its significant points (not "talking points"), and the "nature of the beast." At this stage of specialized machinery with each variety designed for a certain class of work, it is the most difficult matter conceivable to obtain any kind of an intelligent summary of a machine's points from an advertisement.

When an advertisement does state the points of a machine, they are liable to be inconsequential facts of no special interest to a mining man—details indicating nothing of the principle that he is seeking to weigh and understand.

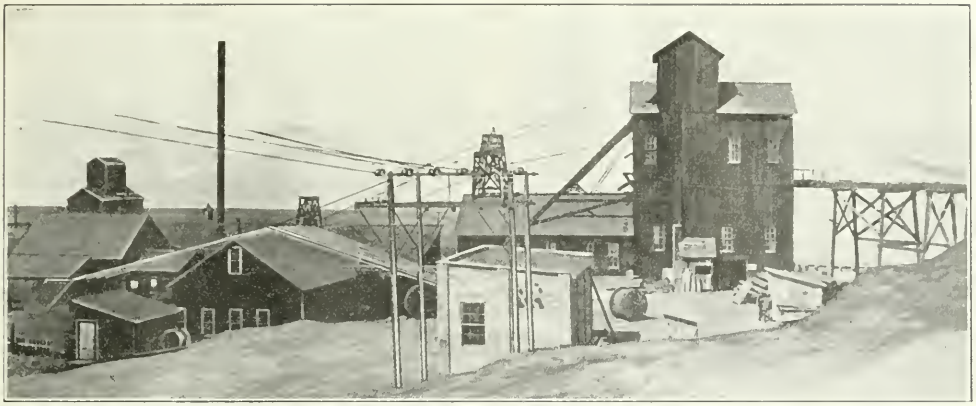
There is nothing more interesting to a mine-superintendent than intelligent information on practical mine-machinery. Some mining-machinery salesmen have the faculty of conveying such information about the equipment they sell. It is sometimes contained in miscellaneous articles in the technical journals. To a large extent it is obtainable nowhere, and the staff at the mine remains in ignorance of whether or not a new machine would do their work, since they do not feel like making a considerable expenditure to experiment with half-a-dozen new departures that may prove failures and disturb the routine at the mine.

Technical advertising, or advertising of more or less specialized equipment in technical publications is too much based on the assumption that the readers are babes in ignorance and incapable of appreciating anything but the insufferably dull and stereotyped nonsense that is too general to mean anything. [In our editorial columns we comment on this expression of opinion.—EDITOR.]

BUTTE has yielded more copper than any other district in the world, the total output to the close of 1913 being 6,154,196,000 lb., or about one-third of the total copper output of the United States. It has produced also $26,268,500 in gold, 275,119,000 oz. of silver, 11,300,000 lb. of lead, and 181,540,000 lb. of zinc. The values of these metals are as follows:

Gold	$26,268,500	Lead	513,500
Silver	191,765,300	Zinc	$12,093,600
Copper	865,794,300		
			$1,096,435,200

A large part of the output has come from an area of but a few square miles, which so far as value is concerned, has undoubtedly been the most productive metalliferous area of its size in the world.



THE PENROSE SHAFT, LEADVILLE, COLORADO.

Unwatering the Down-Town District at Leadville

By AN OCCASIONAL CORRESPONDENT

Of the world's mines and mining districts there are some half score or more that stand out in such contrast as to make those who have knowledge of their mineralization wonder at the magnitude of nature's work. More than once has the discovery of great mineral deposits in some favored country changed the course of world events. Leadville, with a production of around $400,000,000 must be reckoned as one of these great mining districts—not only because of its gross output, but because of the magnitude and variety of its mineralization. For 16 years placer miners worked the gulches throughout the district and tramped over the hills under which lay greater treasure. Then for 31 years practical and theoretical miners reaped a bountiful harvest from the silver, lead, gold, iron, and iron manganese deposits, neglecting veritable mountains of oxidized zinc ore, from which have been shipped millions of tons since 1910.

As is well known to many, the lead and zinc ores occur in sedimentary beds of limestone and quartzite among which are interbedded and intruded sheets and sills of gray and white porphyry. From the eastern part of the district westward there occurs a series of great north and south faults and on the east side of each of these faults the formations have been forced up so that it is like great stair-steps rising from the west to the east. The Carbonate fault passed just east of the city of Leadville, and the formations west of it and lying deep under the city itself are included in what is called the Down-Town district.

The Down-Town district, by reason of the greater depth of the ore-bearing contacts and the presence of water, was not worked until after the more available orebodies had been extensively exploited. Just when the first ore was shipped from west of the Carbonate fault is not known to me, probably before 1890. The Penrose shaft found ore in February 1893. From the first discoveries until 1896 over a dozen different mines were in operation and enormous ore-shoots were opened up; the Penrose, Coronado, Sixth St., P. O. S., and many other well-known shafts were working. In that year a serious strike of miners, which included pump-men, caused a shut-down all over the camp, and the Down-Town district, East Fryer hill and other wet districts were flooded. In 1898 the Home Mining Co. unwatered the Penrose shaft and operated the consolidated mines until 1904, when they turned the holdings over to the Midas Co., which operated until the panic of 1907. Just before closing-down, the Midas Co. sank the Penrose shaft from the 600-ft. level, where the lowest workings on the upper ore-contact had been, down to the 900-ft. level, where an additional flow of water was encountered, so heavy that the pumping equipment proved inadequate.

After 1907 the entire area lay under water, until, through the efforts of former Governor Jesse F. McDonald, about 400 acres in the Down-Town area, including fifteen or more mines, have now been taken under lease and a company organized to unwater and continue the working of the ground. The leases run for 20 years. When the variety of ownership is considered, the securing of leases and harmonizing all the interests was a stupendous task splendidly accomplished.

After considering the many ways of handling mine-water, it was decided to use centrifugal pumps. Sulzer Bros. of Switzerland, famous makers of this class of pump, were considered as manufacturers, but on account of the European war they could not guarantee the date of completion of any pumps nor in any way insure delivery, so negotiations with them were dropped and the

contract eventually let to the Providence Engineering Works of Providence, Rhode Island. Four pumps were ordered; all are just alike except that two have frames to work in the shaft and two are mounted for placing in the station. The pumps were installed in the Penrose shaft and operations commenced on May 8, 1915. From May 8 until June 2 only one pump was running most of the time; the water would be lowered with the two pumps and then held at that level with one pump until the ground was sure to be drained. This was a safety measure to prevent lowering the water too rapidly, which might cause some obstruction to break loose in the old workings and flood the pumps. Since June 8, it has been necessary to run both shaft-pumps. At the date of writing, July 10, the water has been lowered 410 ft. and is being held at that level while a station is being cut for the other two pumps. As shown in Fig. 1 the two station-pumps will work in relays, taking the water from the pumps in the shaft and throwing it to the surface. After the unwatering is completed new pumps will probably be installed on the bottom level that will be capable of throwing the water clear to the surface.

The pumps are vertical two-stage, enclosed impeller type, operating at 1800 r.p.m. The impellers are about 17 inches in diameter and between the blades the five openings are each $2\frac{3}{8}$ in. by $1\frac{1}{4}$ in. giving a combined peripheral discharge opening of 14.84 sq. in. The dimensions of the two impellers are exactly the same. The pumps are designed to handle 1500 gallons under 410-ft. head when running at 1765 r.p.m. They are direct-connected to 300 hp. G. E. induction motors using 3-phase alternating current. The current is obtained from the Colorado Power Co. and the cycle is $61\frac{1}{2}$, which gives a speed of 1800 r.p.m., or 35 r.p.m. faster than the designers of the pump stipulated.

The pump and motor each weigh approximately two tons, but, including the frame-work, suction, and first length of the discharge-pipe, the total weight is about $7\frac{1}{2}$ tons. Fig. 1 shows the arrangement of the cables for handling the pumps. The cables are wound on steam-winches. With this arrangement a three-rope block and tackle is secured. The Penrose shaft is three-compartment; the two outside compartments contain the shaft pumps and in the centre compartment a skip is operated. Another sheave, not shown in the sketch, is placed over each pump-compartment over which pass cables for lowering the lengths of the column-pipe. To start the pumps it is necessary to lower them until the water is above the bottom impeller. Under these conditions the pumps also throw the maximum quantity. As the water lowers on the suction the pumps throw less and require less power, but probably the greatest efficiency is when there is no distance of suction. The discharge column is of 10 in. diam. with screwed flange-joints. The first length above the pump is held by a cross-head working on the guides and into a slip joint of the usual construction.

Some of the mechanical details are worthy of mention. The motor-bearings are oiled from a reservoir at surface. The oil passes down the shaft from the top bearing to the bottom thrust-bearing and into a pan that revolves with the shafting. The centrifugal force throws the oil from this pan into a pipe leading back to the reservoir on top. The pump-bearings do not use oil, but receive water, which is led to them from the discharge-column after being strained to remove any grit. The bottom pump-bearing consists of annular rings on the shafting, which rests on *lignum vitae* surfaces in the bearing. Between the impellers and the bottom impeller and the suction the water is prevented from flowing back by labyrinths or annular rings and grooves fitting into companion grooves in the pump-casing. Under the pressure of approximately 200 lb. some is bound to work by. To prevent a pressure being developed on the top of the upper impeller, the water that leaks by the labyrinths is led through a pipe back into the pump and prevents a serious thrust against the bottom bearing. The smoothness of running is remarkable. The pumps hang in the shaft just like a skip with no wedging or blocking, yet only

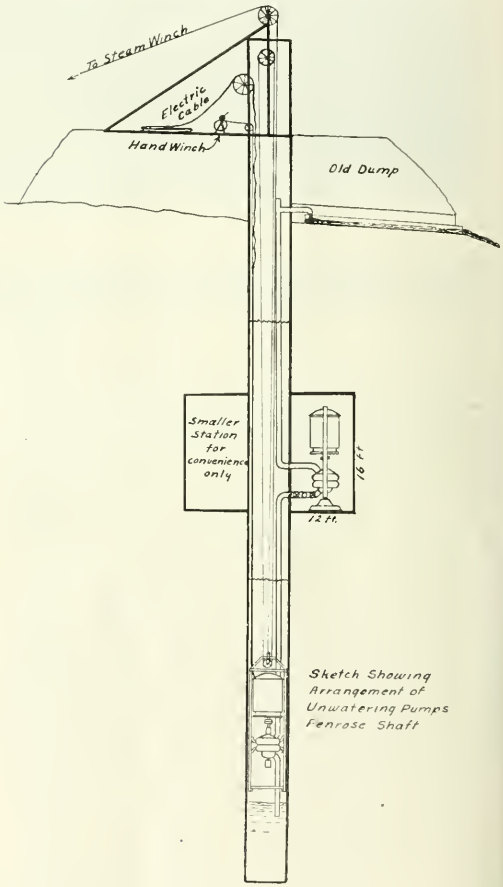


FIG. 1.

FIG. 3. SHOWING THE VOLUME OF WATER PUMPED.

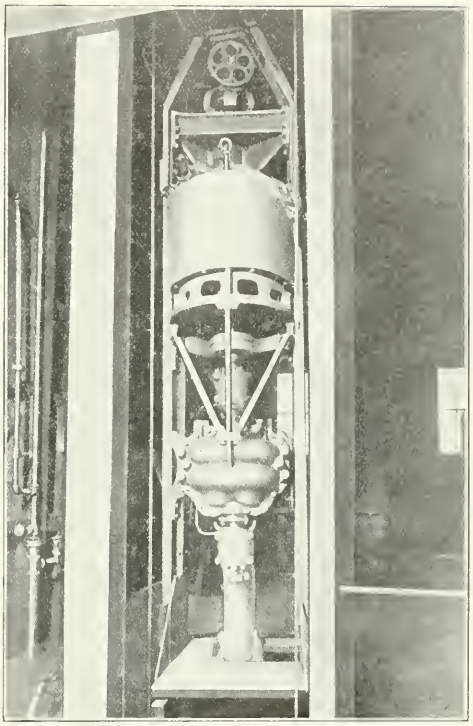

FIG. 2. SINKING PUMP READY TO BE LOWERED.

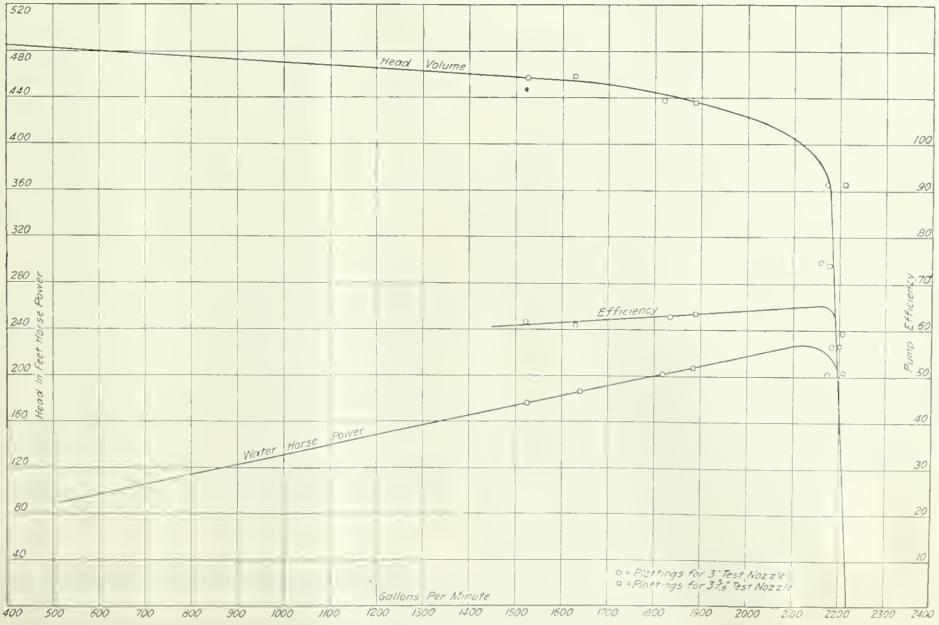

FIG. 4. EFFICIENCY CURVE OF PUMP.

the faintest vibration is noticeable. To those accustomed to the chugging of the steam-sinkers the contrast is very marked. The pump part of the coupling between pump and motor is shown in Fig. 2. The motor part of the coupling is the same and bolts pass through the holes. Hard-rubber washers around the bolts allow a certain amount of 'give' in the coupling. Fig. 2 also gives an idea of the small size of the pumps compared to the volume of water they are throwing, as shown in Fig. 3.

The electrical power comes to Leadville over the main line of the Colorado Power Co., at 100,000 volts. This line, 200 miles long, connects hydro-electric plants at Shoshone in the western part of the state and those near Boulder in the central part. Denver secures a large portion of its power from this line, which is one of the great electric-transmission feats of modern times. At the Leadville sub-station the power is stepped-down to 6600 volts and at the mine it is stepped-down from 6600 to 550 volts. From the mine-transformers the current passes to bus-bars on the switchboard. From the bus-bars the current for each pump passes through two switches to the electric cable leading down the shaft. One of these switches throws the current through an auto-transformer or starting-box and is used for starting the pump. As soon as the pump is up to speed this switch is released and the other switch immediately thrown-in, allowing the current to go direct to the pump. A timing arrangement prevents the running-switch from being thrown-in except just after the starting-switch has been released. The cables down the shaft are all the same and consist of three multiple-strand conductors each of 250,000 circular mills area. These are rubber-insulated and jute-filled. Around the conductors there is a double armour of wire wound in opposite directions, and between the wire armour and outside are layers of marlin. The completed cable is of 3-in. diam. and weighs 12 lb. per foot. Fig. 1 shows the method of holding the cable in the shaft by means of a steel cable wound on a hand-winch.

In Fig. 4 is given a copy of the efficiency curve plotted from the tests on the pump at the factory before shipment. One of the operators present at this test has told me that the pump was sucking about 10 ft. during this test. There is no method of testing the pumps now except in a rough way. It is estimated that the pumps throw 2000 gallons each against the 410-ft. head, which they now have when the water is well up to the pump. As the water lowers from the pump, however, the capacity of the pump decreases. The efficiency of the motor is said to be about 93%. The cost of each pump with its motor is under $4000. Power costs 9 mills per kw.-hour or the company has the option of paying $6.50 per month on the first 100 hp., $4.50 on the next 400, and $3.50 from 500 kw. up. If we assume an efficiency of 60% for the pump and 93% for the motor, giving an over-all efficiency of 56%, the actual cost per water horse-power per hour (including friction in the pipes) is 1.2 cents. I have tested steam-sinking pumps (usually under adverse conditions, however) and the comparison of cost with the above is only about 1 to 10. These are not the most efficient types of electric pumps, the plunger-pumps showing greater efficiences, but when we consider the volume of water thrown compared to the space occupied and the ease of handling, these pumps are deserving of the highest commendation and signify an important step forward in the method of unwatering flooded mines. At the outset some trouble was encountered with the motor, but, since this was remedied, the work has proceeded practically without a hitch. Simeon McDonald is in immediate charge of the work assisted by William Angus, master mechanic. C. D. Criley is electrician and the Providence Engineering Co. is represented on the ground by H. S. Arnold. Every courtesy is shown to engineers and others desirous of inspecting the operations.

Causes of misfires in blasting underground are as follows, according to J. D. Marquard of the Chemical, Metallurgical and Mining Society of South Africa. (1) Improper distribution of detonating force; (2) weak detonators; (3) damp detonators; (4) sawdust in detonators; (5) grease in detonators; (6) working ends of detonators pointing wrong ways; (7) axes of detonators and charges out of alignment; (8) detonators setting charges alight; (9) improper fixing of detonators to fuses; (10) improper fixing of detonator and fuse to primer-cartridge; (11) non-greasing fuse and detonator for wet holes; (12) choking fuse; (13) fuse damaged by tamping-rod; (14) irregular fuse; (15) deteriorated fuse; (16) wet fuse; (17) bunching fuses; (18) omitting to light fuse; (19) bad quality of explosives used; (20) deteriorated cartridges as primers; (21) deteriorated cartridge in between other cartridges; (22) air-cushions between cartridges; (23) tamping in between cartridges; (24) improper tamping or confinement of charges; (25) exudation; (26) running fuse (so-called); (27) improper and unscientific charging; (28) explosives forced into cracks after explosions; (29) explosives burning and smothering charge; (30) cut-outs; (31) insensitive explosives; (32) over-charging; (33) improper cleaning of sludge out of hole before charging; (34) contraventions of the mining regulations; (35) disobedience, indifference, carelessness, etc.

Bombs of military origin are all too familiar. Volcanic bombs consisting of round, elliptical, or discoidal pieces of lava from an inch to many feet in diameter are not so often mentioned. In Bolivia they cover many miles along the railway leading to Oruro. They are formed by explosions of steam in the column of ascending lava in the pipe of a volcano, and are thoroughly molten when ejected. The rotary motion imparted by the ejection gives them a circular form and the amount of "flattening at the poles" is a measure of their rapidity of rotation and fluidity.

House rent at the Treadwell mines is $10 to $15 per month for homes with baths and steam heat, and electric light. Room rent for single men $4 per month; board $25 per month.

Mining and Milling in Wisconsin

By CLARENCE A. WRIGHT

*The Wisconsin lead and zinc district includes not only the southwest corner of Wisconsin, but also the adjacent parts of Illinois and Iowa. The district has produced lead ores for many years, but now the zinc output is of increasing importance, having risen from 11,540 tons of spelter in 1906 to 35,088 tons in 1913. The lead production is only about one-tenth the latter figure.

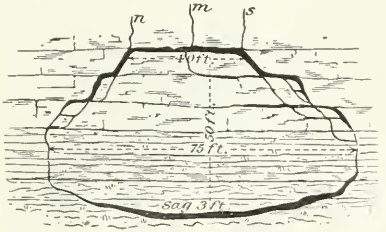
The ores consist chiefly of sphalerite, smithsonite, galena, and marcasite, and occur principally in the Platteville (Ordovician) limestone, or near the base of the over-lying Galena limestone, either in crevices, joints and openings, or disseminated throughout the limestone. The fissures, known as 'ranges,' are in many places parallel, having a nearly east-and-west direction, though there is a subordinate north-and-south system; they are best developed in the upper ore-beds. 'Pitches and flats' are characteristic of the district. Most of the sphalerite is found in them. These occur principally in the Galena limestone; below them are found the disseminated deposits. Above and near the level of ground-water, most of the galena and smithsonite are found, below that level sphalerite and marcasite predominate, though a little galena is present.

Prospecting is commonly done with a churn-drill, as the orebodies are not deep-lying. It is usually done by contract at 75c. to $1 per foot; the holes are placed 100 to 300 ft. apart, using intermediate holes for definitely determining the outline of orebodies when found. Churn-drills are better for this purpose than diamond-drills, as the quantities of flint occurring in the limestone give less trouble, and the 6 to 7-in. hole made by the former gives a better sample than the 1½ to 2½-in. core of the diamond-drill. Prospecting is aided by the ascertained fact that bodies of blende are more apt to be found below groundwater-level where lead ores are known to occur above.

Mining is done through vertical shafts, 100 to 200 ft. deep, and usually only from one level, as few of the orebodies are over 40 ft. thick. Underhand stoping is the usual practice, using one or two benches, according to the height of the face. The broken ore is allowed to work its way to the bottom, where it can be shoveled into cars. Special care must be taken to guard against falls of roof. Little timber is used, pillars 10 to 20 ft. thick being left at intervals of 20 to 50 ft. The average distance between shafts is 300 ft. They are cribbed from the surface down to solid rock, and few of them have ladderways, the men being raised or lowered in the buckets and cages.

Several makes of air-drills are used. The holes are 6 to 8 ft. deep in stoping, 10 to 14-ft. holes are drilled in taking up the lower benches. The powder most in vogue is 40% gelatin, although ammonia dynamite is largely employed where the holes are fairly dry. The drillers prepare the cartridge and load the holes themselves. The quantity of powder averages 1 lb. per ton of rock broken. A piece of sheet-iron is commonly laid down for the convenience of the shovelers, who load the ore into cylindrical 'tubs' 28 by 30 in. that hold 1000 lb. each. These are pushed by hand or hauled by mules to the shafts. Where cars are used they are hoisted in cages. The water occurring in the mines, varying from 200 to 1500 gal. per min., is easily handled.

Both electric and steam hoists are used; no attempt at counterbalancing is made, the buckets being hoisted by power and lowered by gravity. Signaling is done by



PITCHES AND FLATS. *m*, *n*, AND *s* ARE CREVICES.

pull-bells, but a few electric bells are in use. When the bucket has been hoisted to the top of the head-frame, the hoist-man covers the shaft with a lid, to prevent any material falling down it, and then dumps the load into a chute leading directly to the grizzly over the storage-bin. The latter, built of timber and having a capacity of 100 to 200 tons, usually serves as the mill-bin. Where more than one shaft supplies the mill, the ore is trammed to the mill-bin by surface or aerial tramways.

The mills of this district are much like those at Joplin, but are smaller and have less capacity, as more iron sulphide is present and the feed of the jigs must therefore be lighter. The mills range in capacity from 75 to 150 tons per 10-hr. shift. They are usually built of wood on concrete foundations and are of the level-site type. The course of the ore through the mill is shown by the accompanying flow-sheet. The large pieces caught on the grizzlies are broken by sledge-hammer; 5 to 25% of waste is thus sorted out and rejected. The work is done by the screen-men, who are paid $2.30 per day. The undersize, under 5-in. ring, goes to the mill-bin, whence it is fed to Blake crushers that reduce it to 2-in. ring. It next goes to a set of rolls, which reduce it to ⅝-in. size, and then by an elevator to trommels 6 to 12 ft. long, 3 ft. in diameter, and with 1½-in. holes. The undersize goes

*Abstract of Technical Paper 95, U. S. Bureau of Mines.

to the first jig, the oversize to a set of rolls and back to the trommel.

The Cooley jig, similar in principle to the Harz, is most in use. Sometimes rougher- and cleaner-jigs are used, in other mills only one jig is employed. This latter is satisfactory for ore in which the minerals are coarse and there is a large proportion of marcasite. It has the advantage of lower first cost, and requires less labor, power, and repairs. In the one-jig system eight cells, divided into two sections, are usual. The lead concentrate, if any, is caught in the first cell, and zinc concentrate on the first, second, third, fourth, fifth, and six screens, and the hutch of the seventh. The middling is re-crushed and returned to the feed. In handling the fine material tables are little used, for they do not yield a clean concentrate, as the marcasite and sphalerite have almost identical specific gravity. In one case tables are used to save the iron sulphide, which is shipped to acid plants. The usual practice is to obtain as much of the zinc material as possible from the jigs, the overflow water being allowed to return to the pond. Tests have been made with Wilfley tables, which showed that the iron and zinc sulphides would be successfully separated, but it is still a question whether enough 40% zinc concentrate can be obtained in this way to make the operation profitable.

Most of the concentrate ranges from 30 to 40% zinc and is subjected to a light roast in revolving cylinders, lined with brick, and then passed through magnetic separators. In this way the zinc content is raised to 57 to 60% Zn. Operators that have no roaster haul their concentrate to the local roasting-plant for treatment. The total cost of treatment is $2 to $3 per ton. Average assays are as follows:

	Zn%	Fe%
First concentrate	33.91	17.85
Second "	59.53	1.99
Middling produced	8.71	....
Tailing "	4.64	....
Zinc recovery	91.54%	

Losses occur in the mining, where 15 to 30% of the ore is left in pillars; a little zinc is also lost in the waste sorted out. The greatest loss is in milling, the average recovery being 70 to 75%. The recovery in the second concentration is 90 to 95%, or a net recovery of 65 to 70%. Including the losses in smelting the net recovery of spelter from the mine is probably 40 to 50%. Few of the companies have any exact records as to the losses incurred.

Labor conditions in the district are much the same as at Joplin; there are no unions. Underground the shift is 8 to 9 hr., for surface and mill-work the time is 9 to 10 hours. A few companies operate two shifts throughout; two shifts underground and one in the mill is more common. The average wage is $2.61 per shift, and ranges from $2.27 for surface labor to $3.08 for engineers and helpers. Living costs are low and the work is steady, so the scale does not compare so unfavorably with the wages in the Rocky Mountain states as might be supposed.

It is difficult to obtain representative figures of cost, as the methods of bookkeeping used by the various companies are so diverse. The following costs, however, represent the average of several of the most important mines and mills. The cost of power is not distributed

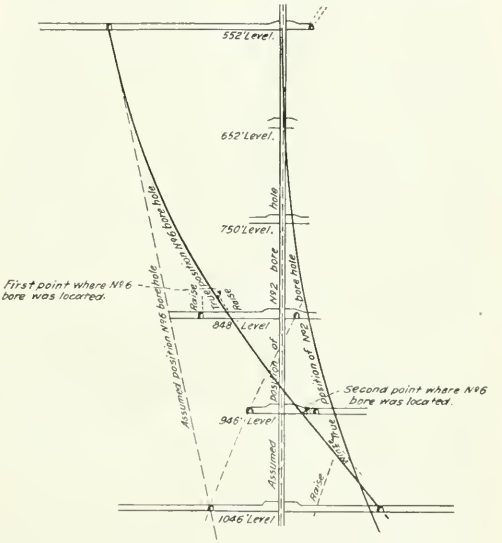
Deflection of a Diamond-Drill Bore

By ERNEST T. PRESTON*

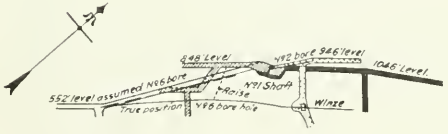
†In May, 1902, a vertical diamond-drill hole (No. 2) was started at the bottom of the No. 1 shaft on the Iron Duke lease of the Associated Northern Blocks, at a point 562 ft. below the surface. After boring for 622 ft. or to a depth of 1182 ft. from the surface, shaft-sinking was resumed upon the bore-hole, which retained its vertical course for about 50 ft., when it was found that the hole started to deflect to the east and north, leaving the shaft at about 100 ft. Cross-cuts were driven at the 750-ft., 848-ft., and 946-ft. levels, each one in turn exposing the hole but not the ore that had been reported at 948 feet.

The accompanying plan and section will illustrate the course taken by this borehole.

No. 6 bore-hole was started in September from a point in the west cross-cut on the 550-ft. level at an angle of 78° and N 28° E, its purpose being to confirm the assays reported in the No. 2 hole. When 490 ft. of boring had been done ore was reported and continued with increasing assay-value to 500 ft. This apparently practically confirmed the results reported from the No. 2 hole. On the assumption that the hole had not varied greatly from its theoretical position, a cross-cut was started west at the 1046-ft. level. Strangely enough, where the ore should have occurred, a low-grade pyritic lode was encountered; prospecting was at once started in this lode by driving and raising, but the assay-values cut out and no hole could be found. The company's surveyor, R. Falconer, then made a survey of the hole, with a clinostat made by W. R. Bawden, which showed the hole to have flattened considerably, but no correct bearing for direction could be arrived at, the difference in the compass-readings being so great as to completely condemn them. The next work was a cross-cut west at the 848-ft. level, in the hope of picking up the hole there, but after a large amount of driving, raising, and cross-cutting, no results were obtained and this cross-cut was discontinued. At this time Mr. Falconer left the mine and the writer took over the surveying for the company. My first work was to re-survey the hole, checking it several times, with practically the same result as that obtained by the previous survey in regard to underlay, but the compass-readings differed as much as 90°. The jelly used was most probably the cause of this trouble, as after the needle had been submerged in it for about a day the jelly seemed to attack the needle and the pivot on which it swung; the steel became soft and completely demagnetised. Another trouble was to get the jelly to set, as it had to be made very thin to enable the needle to work with as little resistance as possible, and, again, the jelly would not set properly at a temperature greater than 65 to 70° F. This hole was full of water and the temperature was 78°, so that fully two-thirds of the time when the clinostat was drawn up the jelly would not be set, which meant re-melting and lowering again. This difficulty can, I think, be overcome, as in mentioning it



Transverse Section N°1 Shaft.



Plan View

Scale; 1 Inch = 120 Feet.

to Mr. Mann, Government Analyst, he suggested trying Agar jelly, which is a pure vegetal matter and does not attack the needle. Another great advantage is that Agar jelly will set at 104° F., and as there is only 1% of solid used it is very thin when heated and therefore offers little resistance to the needle. So far, my experiments with the jelly have been conducted on the surface only.

The clinostat survey was accepted as to dip, and it was also assumed that the bearing had not altered from the direction at which it started. An east cross-cut was put in at the 1046-ft. level, and, when under the point where the ore was expected, a raise was put up for a distance

*Since deceased.

†Abstract *Monthly Journal* of the Chamber of Mines of Western Australia, at Kalgoorlie.

of 40 ft., in which was encountered a small pyritic body of no value. This work was then stopped, the raise being too high to work conveniently. The next thing was to have a strong magnet made and lowered down the hole to the 848-ft. level, where most of the work was done, to see if any attraction could be noticed on the compass-needle of a theodolite fixed at this level. This was quite a failure, as after experimenting on the surface with the magnet connected with the dynamo with a current of 110 volts, no attraction could be noticed when the magnet and needle were more than 10 ft. apart.

As there was a quantity of water coming through the rock in several places overhead at the 848-ft. level we thought that some of this water might be from the bore-hole. To test this a strong solution of permanganate of potash was put down the hole and within half an hour the colored solution could be seen percolating through to the 848-ft. level; this was equal to a depth of 310 ft. down the hole. A raise was then started to follow up the discolored rock; the raise went up very flat for about 50 ft. in a south-easterly direction when the coloration was lost and although more of the solution was put down the hole it would not percolate through. It was thought that the 'firing' in the raise must have blocked up the hole, and being doubtful as to whether we should open up the raise to the left or right, we sounded by lowering a double fuse and two caps down the hole and firing them. At this level this test proved the hole to be on the south side of the raise, and we thereupon opened a stope for 12 ft. and exposed the hole. (See plan). A survey made to fix the exact position of this point disclosed the fact that the hole at 300 ft. had deviated in bearing 18 ft. and had flattened 60 ft., the angle of dip being 58° instead of 78° as started.

This result proved the clinostat survey to be practically correct as far as dip was concerned, and gave us an idea of the direction, but not the exact bearing, because the line of the bore took the form of a curve. From this datum careful calculations were made to determine at what point to start driving from the east cross-cut to find the hole at the 948-ft. level. Having determined this, a drift was put in, but without any good result, and, failing to find the hole at a given point, the drift was continued another 20 ft. We then stoped back along the drift, thinking we were under the hole. This work, also, was unsuccessful. The hole being blocked just below the 848-ft. level, we were prevented from sounding, so the diamond-drill was called in to push the obstruction down; this was easily done for about 50 ft. in two shifts; then the obstruction became hard and fast, and could not be moved, notwithstanding the weight of 400 ft. of drill-rods with a drop of from three to ten feet. This work was continued for four days without perceptible success. Instructions were then given to stop at the end of the shift. Almost immediately the obstruction began to move and within four hours the hole was cleared down to the depth required. A few shots were then fired down the hole at the 948-ft. level, which sounded to the west of the drift, and a cross-cut put in for a distance of six feet exposed the hole. From this level a winze was sunk following the course of the hole down to the point where ore had been reported. The winze was continued for a further 20 ft. and then stopped with the intention of connecting it with a raise from the 1046-ft. level.

A survey of the hole made with the theodolite proved that from the 948-ft. level to the bottom of the winze; the hole had not continued its curvilinear course either in dip or direction, but had kept the one straight line for this length, showing that one cannot make certain of picking it up at any distance ahead.

Coeur d'Alene. The production of this district for 1913 was as follows: Gold, $81,749; silver, 9,337,109 oz.; copper, 5,097,894 lb.; lead, 296,740,946 lb.; and zinc, 21,415,565 lb., valued in all at $20,767,410. The total value of all the metals produced in the district since mining began is approximately $262,608,000. The rocks in which the Coeur d'Alene ores are found belong to the Belt series. These beds in the Coeur d'Alene district have been crumpled into folds and have been intruded by masses of molten material which, on cooling, solidified as a granitic rock known as quartz monzonite. During or after the solidification of the igneous rock the region was broken by cracks that caused displacements amounting to thousands of feet, producing what the geologist terms faults. In other places, where the disturbance was less, hot solutions, probably connected with the intrusion of the granitic rock, deposited the ores, partly as fillings of open cracks but largely as replacements of the adjacent rock by chemical processes. After the intrusion of the granite and the formation of the deposits of ore, an uneven layer of rock, probably some thousands of feet in thickness, was gradually removed by the action of weather and streams. This erosion exposed the once deeply buried granite and the ore. The principal mineral of the lead-silver ores is galena (sulphide of lead), which in this district invariably contains some silver. Other common minerals of metallic luster associated with the galena are pyrite (sulphide of iron), pyrrhotite (magnetic sulphide of iron), chalcopyrite (sulphide of copper and iron), and sphalerite (sulphide of zinc). The characteristic waste mineral of non-metallic luster associated with galena, that is, the gangue of the ore, is siderite (carbonate of iron). The ores, as mined, carry, as a rule, from 5 to 50% of lead, and from 3 to 45 oz. of silver to the ton. All but the highest grades are concentrated in the district, by milling, to a product containing about 50% of lead and from 15 to 55 oz. of silver to the ton.

The departments at Washington receive annually 43,000,000 communications and dispatch 22,000,000—a total of 65,000,000 in a year. Twenty-five million of these are filed at a cost of $260,000, or about a cent per document. The expense of filing varies from $6.53 per thousand in the Post Office Department to $20.53 in the Department of the Interior.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Ratio of return to initial feed of tube-mills at the Tonopah-Belmont mill is 0.91 to 1, or total feed 127.38 tons, initial feed 67.18, and return feed 60.20 tons.

Zinc in cyanide solutions from precipitation sometimes combines to some extent with the sulphur in them, similarly to the lead in lead acetate to treatment solutions.

Smoke combustion or smoke burning are not considered good terms in the discussion of furnace firing. When once made, lamp-black is incombustible and cannot be burned.

West African mining companies have had short lives. Of 260 companies formed in 1901 only 20 were alive in 1911, and of these but five or six have paid dividends, and only one company has done really well.

Money has not always consisted of gold, silver, and copper but various other substances have been used among which may be mentioned cattle, rice, cacao, oil, rock-salt, wampum, tobacco, brick, tea, dates, beans, sealskins, sables.

Labels may be paraffined by dissolving paraffin in CCl_4, and using a saturated solution as a varnish. To prevent the adherence of drops of liquid to the inner surface of volumetric vessels, coating them with a layer of pure paraffin has been successfully tried.

Corundum is for the most part a pyrogenic and primary mineral occurring in aluminous rocks of syenitic and gabbroic type. These are not confined to one locality, but have been recognized and fully described in Russia, India, California, Montana, Colorado, and Ontario.

Unique mining methods were seen by the *bachelier* Martin Fernando de Encisco in 1510, when, so it is related, he saw the natives in the Province of Zeno, east of the Gulf of Darien, catching in nets the coarser particles of gold, that were brought down by the mountain torrents.

Sulphocyanide amounting to about 2.7 lb. is carried in solutions at the Tonopah-Belmont mill. While this cyanide combination does not hinder the dissolution of gold and silver—except in so far as this or any inert salt tends to increase the viscosity of the solutions—still it is a combination of cyanide that it is almost impossible to break up, and must therefore be considered as a part of the cyanide consumption.

Zinc is a highly crystalline metal, and its tensile and transverse strength depend entirely on the size of the crystals. The tensile strength varies from about 2 tons per sq. in. with coarse crystals, to 7 tons with very fine-grained ones. The transverse strength also varies with the crystallization, being greater the finer the grain. The modulus of rupture is from 4 to 11 tons per square inch.

Sulphur and yellow fever are not usually thought of together, but it was the employment of 300 tons of sulphur and 120 tons of insect powder, the entire supply of the United States, that enabled Gen. Gorgas to destroy the mosquitos in Panama and so thoroughly eradicate yellow fever that no case has occurred since May 1906. Before the use of sulphur and other sanitary measures the annual death-rate from yellow fever expected, on the basis of the French ratio, was 3500. The death-rate per 1000 during the French occupation was 200 per 1000. In ten years of the American control the rate was 17 per thousand.

With reference to the power of the state and county to tax unpatented mining claims, we can do no better than to quote from a decision of the U. S. Supreme Court (Elder *v.* Wood, 208 U. S., 226-232): "* * * Such an interest from early times has been held to be property distinct from the land itself, vendable, inheritable, and taxable. [Cases cited.] The State therefore had the power to tax this interest in the mining claim and enforce the collection of the tax by sale. The tax deed conveyed merely the right of possession and affected no interest of the United States." It will thus be seen that this power to tax unpatented mining claims is unquestioned. The purchaser at such tax-sale merely succeeds to the possessory title owned by the tax-delinquent and of course has to comply with all the conditons of the mining laws. He merely steps into the shoes of the locator.

Contact-deposits originate through the action of volcanic magma at a high temperature, especially when under pressure and the contained fluids and gases have no chance to escape into the atmosphere. The deposits are therefore essentially the product of intrusion. The zone thus subjected to metamorphism, and of which the outer border keeps more or less parallel to that of the intrusion, is termed the contact-zone. In it the ore deposits are usually concentrated in the immediate neighborhood of the intrusive, or not far from it. Close to the actual contact of this rock with that through which it was forced, fragments of the latter are often found imbedded with the ore in the intrusive. These occurrences are usually the result of the alteration of limestone to oxide or sulphide ores. Where earthy limestone originally existed the calcareous constituents become altered to white crystalline marble, while the argillaceous material crystallizes as garnet, vesuvianite, scapolite, augite, hornblende, epidote, etc. It is generally accepted that such a re-crystallization is brought about by hot solutions or steam escaping from the magma. It must be pointed out that the expression 'contact-deposit' is unfortunately even today applied a good deal to occurrences having nothing to do with contact phenomena, but which by chance occur along the plane where two rocks come in contact. This wrong use of the term should in all reason be avoided.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

TANGANYIKA CONCESSIONS.—UNION MINIÉRE DU HAUT KATANGA OPERATIONS.

In many ways the position of the Tanganyika Concessions and the Union Miniére du Haut Katanga at the present time is of unusual interest. In spite of the Union Miniére offices being in Brussels, and the directors and shareholders scattered, it has been possible to house some of the staff at the Tanganyika offices in London, and to continue development of the great copper enterprise in the Belgian Congo. The Tanganyika was formed 16 years ago by Robert Williams to acquire concessions in northern Rhodesia from the British South Africa Co., and has through a subsidiary, the Rhodesia-Katanga Junction Railway & Mineral Co., done much to open communications with the south and to develop copper deposits

MAP SHOWING SITUATION OF TANGANYIKA CONCESSIONS.

at Kansanshi. But by far the most important work has been in connection with the great copper belt in the Katanga territory of the Belgian Congo State, just over the Northern Rhodesian border. A 40% interest was acquired in a Belgian company called the Union Miniére du Haut Katanga, formed to acquire the territory, the remaining 60% being held in Belgium. The technical control has been with the Tanganyika company, and the development of the deposits and the metallurgical treatment have been under the direction of Mr. Williams and his staff of engineers and metallurgists. The surface extent of the copper deposits caused the usual unwarranted boom in the Tanganyika shares six years ago, but, as pioneers of empire, we mining engineers must not blame the directorate of the Tanganyika Concessions for the rosy reports circulated in those days, or for the subsequent fall in the shares when the real business commenced. In addition to the development of the copper deposits, it became necessary to find an outlet to the west coast of Africa, and so avoid the long railway haul to Beira on the east coast or to Cape Town, and to shorten the sea journey to England. The energy of Mr. Williams was with this object in view, devoted to the building of a railway from Benguella on Lobito Bay in Portuguese West Africa, to Katanga. This work is being done through the agency of a Portuguese company, the Benguella Railway Co., the capital of which has been supplied by the Tanganyika company. The railway has been built from the coast inland for 322 miles, and the local traffic is sufficient already to yield a profit. One thousand miles of rails have yet to be laid before connection is made with Katanga, and under present conditions it is obvious that further progress must be slow. In the meantime the copper produced has to be shipped by way of Victoria Falls to Beira. Perhaps a short cut on this route may before long be provided by means of a connecting line from Salisbury to the Rhodesia Broken Hill. The copper belt of the Katanga extends for 200 miles, and many surface workings have exposed large amounts of ore. The ore is all oxidized, and in the absence of technical details much debate has taken place in London and elsewhere as to its exact genetic nature. So far, investigation at depth by drilling has not proved the existence of bodies of sulphide. There is no need to worry about this, for the estimated reserve at the various workings totals 40,000,000 tons averaging 8% copper, with indications by shallow drilling of continuation of similar ore in depth. Smelting commenced in 1911, when 997 tons of copper was produced. The figures of copper production for 1912, 1913, and 1914 were 2492 tons, 7407 tons, and 10,722 tons respectively. Additional blast-furnaces are being built, and the output for 1916 will be about 25,000 tons. The Star of the Congo, the Kambove, and the Luushia mines are the chief producers, and their total proved reserves are estimated at 6,000,000 tons, of which 1,200,000 tons is smelting ore averaging 15% copper. From the other 4,800,000 tons it is estimated that about 25% can be concentrated so as to yield 400,000 tons averaging 18% copper. The remaining 4,400,000 tons of ore will assay 6% copper, and plans are now in hand for concentrating this. During 1914, the smelters treated 92,381 tons of ore, for a yield of 10,722 tons of copper. The working cost at the smelter is estimated at £29 12s. 10d. ($142.28) per ton of copper. Owing to the disorganization of the Union Miniére office, no accounts can be presented, and the Tanganyika, which depends on the Union Miniére for its income, is in the same position. The Tanganyika debenture interest cannot be paid for this reason, and the courts have sanctioned the postponement of payment until after the close of the War. The Tanganyika enterprise, in the heart of Africa, may appear to be of little interest to Americans, but American mining men and metallurgists have been, and are, of substantial service. We must not forget the old Californian, John R. Farrell, who served the Tanganyika well in the early days and demonstrated the extent of the deposits. More recently the services of A. E. Wheeler, of Montana, have been requisitioned and he has in hand the construction of the new blast-furnaces. An American who was consulted in connection with the smelting problem six years ago was Walter G. Perkins. For some reason or other differences of opinion arose almost at once between Mr. Perkins and the staff, and the benefit of his experience was unfortunately lost to the company in consequence. It is clear therefore that the future of the Katanga copper enterprise will be of interest to both English and Americans.

CRIPPLE CREEK, COLORADO

Rain Delays Surface Work.—Portland Operations.—Elkton Water-Level and Lessees.—Blue Bird.—Kavanaugh and Gaylord Mills.

The past week has been a very quiet one in mining circles here. The recent heavy rains have greatly interfered with surface work. Rain apparently is nearly over, and production from dump leases should soon increase. Several of the small local mills which have been shut down are again treating low-grade ores.

The Portland company is cutting a station on No. 18 level at No. 1 shaft. This will make the level about 1850 ft. below the collar. At the Portland-Independence property the storage-battery locomotive is busy hauling ore from the adit to the mill. This material is obtained from the workings above the adit level, and from the surface.

At a recent directors' meeting of the Elkton Consolidated company Jas. F. Burns gave in his resignation as a director. No one was elected to fill the vacancy. Company work at the Elkton is rather limited at present. The water-level has not receeded sufficiently to allow of much being done. The shaft is nearly 300 ft. above the level of the Roosevelt drainage-tunnel. It is expected that in six months' time the adit will be past the Elkton shaft, and the water will be drained to the tunnel-level. At present there are about 50 sets of lessees at the property, and these will continue to work as usual. During the past week a second shift has commenced work in the drainage-tunnel, so that the footage will be at least doubled.

At the Blue Bird property on Bull hill the leasing company is showing considerable activity. No sub-lessees are working. It is the intention of the company controlling operations to open large quantities of medium and low-grade ores. In this way the modern mill, which is to be erected on the property in the near future, may be kept working at full capacity.

The Kavanaugh mill on the Jo Dandy property, and the Gaylord mill on the Dante, are again at full capacity. These mills have been shut down for several weeks. During this time the machinery has been thoroughly overhauled, and everything put in shape for steady operation.

GOLDFIELD, NEVADA

Operations of the Pioneer Consolidated: Development, Mill, Low Costs.

In the Pioneer district, 55 miles south of Goldfield, the Pioneer Consolidated Mines Co. has just increased the operating time of its 10-stamp mill from 12 to 16 hours per day. Heretofore the plant has been treating about 30 tons in 10 or 12 hours, and when operated full time it is said there will be no difficulty in treating 75 tons per day. J. K. Turner, of the Jumbo Extension Mining Co., is consulting engineer for the Pioneer Consolidated. He has lately sampled the newer workings of the mine with satisfactory results. On December 24, 1914, a cave-in occurred in the main stope, known as the Bonanza stope, while it was being examined by W. J. Tobin, president and general manager, and he and a miner were seriously injured. Thereupon the mine was closed and only resumed, on Mr. Tobin's return, early in July last. The Bonanza stope produced upward of $200,000 worth of high-grade shipping ore some 10 years ago, and recent development near the walls has revealed a large tonnage of good mill ore, together with some ore of shipping grade. Mr. Turner took samples at the point of the cave-in, on the 150-ft. level, across 5 ft. and for a distance of 20 ft., averaging $26 per ton. Three samples from the east side of this stope, across 5 ft., averaged $16.13 per ton. A sample from near the top of the No. 9 chute, across 5 ft., yielded $12.80 per ton. Five samples from the west side of the stope, on the 130-ft. level, each across 10 ft., averaged $14.32 per ton. One sample at the west side, on the 140-ft. level, across 5 ft., and for a distance of 15 ft., gave $16.60 per ton. A sample at the northeast end of the stope, on the 170-ft. level, across 5 ft. and for 15 ft. in length, yielded $13.20 per ton. The assays are all gold, there being no other metal present, and all the ore is free-milling. Recovery in the mill is entirely by amalgamation, and with new screens and re-silvered plate for the Huntington mill it is expected that an extraction of at least 80% will be effected. The ore is crushed to 1½ in. and fed to the batteries by automatic feeders. Amalgamation is done in the batteries, on sets of 6-ft. plates below them, then in the 5-ft. Huntington mill, and on 12-ft. plates below the Huntington. The ore passes through a 6-mesh screen in the mortars and 40-mesh at the Huntington. The orebodies are of uniformly large size, and a single man breaks sufficient ore for the mill and trams this quantity to the cages. At the surface, one man trams the ore to the mill-bins, and attends to the crusher and feeding; one man operates the electric hoisting engine and does all blacksmithing, and one man operates the mill. The entire force, including manager, comprises 11 men. Total operating costs are less than $3 per ton. The amalgam is retorted in the company's assay-office and shipped in the form of bullion to the mint. A promising discovery has been made lately at the surface, about 400 ft. northwest of the main shaft and near the old Rickard lease shaft, operated several years ago by "Tex" Rickard. A body of quartz is exposed, from which good pannings are obtained, and development is in progress at this point. The main orebody has lately been exposed in a raise from the 256-ft. level, southwest of the Bonanza stope. The recent sampling shows approximately 1000 tons of good mill ore broken in the mine. At Mr. Turner's advice, Mr. Tobin is starting a large amount of new development work, on all levels. The Bonanza stope, which is over 20 ft. wide in places, has been completely timbered with square-sets. A station is being cut at the 75-ft. level of the Rickard shaft, which is equipped with a good hoist. A cross-cut will be driven to the lode recently found at the surface. The collar of this shaft is 160 ft. higher than that of the main shaft. Work will be started at several other points in the district within the next month.

ELY, NEVADA

Nevada Consolidated Operations.—Tungsten Production.—Gold and Zinc.

The Nevada Consolidated Copper Company is operating at full capacity. New machinery for additional electric power has not yet been received. The manufacturers are paying a penalty of $25 per day and are too busy making war munitions. It has been thought for some time that the company was short of dumping space. The Coppermines company had the Nevada Consolidated surrounded, and the latter could get no more depth in the Eureka pit. The Nevada Consolidated is widening the railroad right-of-way, south of the depot, at Copper Flat, and also the entrance to Eureka pit. This will enable the company to lay the main line over to the east of its right-of-way, and leave plenty of space to cut down along side, commencing back 1000 ft., and make a much better grade into Eureka pit than now and enable deeper work there. The company has acquired from Dick Reipe the old townsite of Junction City, about three miles below the pit, 140 acres of patented ground, which is 125 ft. below the depot level. Double tracks are being laid and will be used for overburden, giving sufficeint area for a long time. This is a down-hill haul, loaded, against a heavy up-grade to the present dumps, which will largely compensate for the additional length of haul.

The U. S. Tungsten Co., just south of Osceola, this county, has for some time been working its mine and mill with about 25 men, and turning out about 800 lb. of about 60% concentrate, which is hübnerite. Development on the vein at 600 ft. shows about the same conditions as near the surface, namely, high-grade shoots or lenses of ore.

Some San Francisco people are mining and shipping scheel-

ite from Sacramento pass, two miles north of Osceola. They are erecting a mill on John Tilford's scheelite claim, in Snake creek, above Garrison, having a contract for the ores. They are investigating the country for scheelite.

A. R. Shepherd has taken a bond and lease on the Sims-Olsen hübnerite property in the north end of Spring valley in the northeast corner of this county and will soon commence work. There is a vein 13 to 20 ft. wide in granite, with fine walls and slickensides, and can be traced about 3000 ft. on the surface. There are also three other parallel veins, all with shearing-planes, from 2 to 5 ft. wide.——The Red Hills lead mine, not far from the Sims-Olsen, is being worked, having recently shipped a carload of ore.

At Willow Creek, southeast of Ely 100 miles, in Nye county, but tributary to Ely, Salt Lake men have recently become interested in the Willow Creek Consolidated Gold Mining Co., having an option on a majority of the shares. Development has been started. One vein has recently been opened, and at shallow depths for several hundred feet in length shows considerable free gold.

The Mud Springs lead mine, 25 miles from Currie, is being worked by Mr. Morrison.——Woodward and sons and others of Salt Lake City are shipping considerable calamine from the Polar Star mines in the northwest part of Clover valley. ——Other people are shipping a zinc concentrate and lead concentrate from Shorts zinc mine, on the west side of Ruby valley.——The Giroux Consolidated copper mines at Ely appear to be dead, nothing having been done for over a year.

JOPLIN, MISSOURI

Zinc Prices Again Strong After Temporary Decline.—Large Deals.—Development in West Joplin District.

Zinc-blende prices, which were quoted at $80 to $110 per ton, basis of 60% metallic zinc, at the beginning of August, declined to $50 to $70 at the close of the month; but the first week of September saw bids suddenly advancing to $75 and $90, this being the quickest advance in the history of the local industry. In a single week calamine, which had sold for as low as $35 per ton, rose to $70. The cause of the changed conditions is doubtless due to the manipulation of the spelter market which, from a high level of $26 per cwt., paid several months ago, had dropped to $11. While metal prices were at this low point, relatively speaking concentrate likewise declined to a figure which seemed low when compared with the high prices that had prevailed. Buying was heavy during the week or two that prices were so low. Spelter has now gone to $16 per cwt., which, judging from conditions, is abnormally high. Throughout the Missouri-Kansas-Oklahoma district there was a general feeling that the lower prices would remain, the result being that a number of large mines were shut down, and many large operators were on the point of discontinuing production when the sudden change for higher prices came about. The temporary handicap that was given to new development has now been partly overcome, and much important work is under way.

Mining deals of importance have been features of the past few days. The Athletic Mining Co., of Webb City, Missouri, of which C. T. Orr is general manager, purchased from A. W. and W. A. Van Haften the Gopher mill and lease at Duenweg, Missouri, for $70,000. This mine is now being operated under the name of the Athletic Mining Co. No. 2. The property was opened several years ago by the Lincoln Mining Co., and later taken over by the Van Haften Co. While it has been a steady producer, profits have not been large, due to the fact that during the greater part of the time the mine was worked, metal prices were low. Within recent months, however, the property was making good profits. Sheet-ore was worked at a depth of 240 ft. The purchase price included the 500-ton mill, and a first lease on 40 acres of the Jasper County Royalty Co.'s land. In addition to this 40-acre tract the Athletic company had already acquired an adjoining lease on 120 acres, on which the old Wolfsheart and San Gabriel mines were situated. The company contemplates the erection of one or two concentrating-plants on this property.

Another mining deal was the sale of the La Nora B mine by G. Bayless and associates to L. L. Hutchinson and others of the Glenn Pool oil district, Oklahoma, for $30,000 cash. This pays for the lease on the mill, which is of 300-ton capacity, and first lease on 52 acres of the Higgins Land & Mining Co.'s property, one mile west of the city limits of Joplin. Bayless took over the La Nora B mine 10 months ago. Formerly it was worked under the name of the Martha Ball, and was not a steady producer. Deeper and more extensive work done by the new company places the La Nora B in the front ranks of the big West Joplin producers. Mining is under way at a depth of 170 ft. in thin sheet-ore formation, the extent of which has been shown by a great many drill-holes. The work of the La Nora B has been confined to 25 acres of the 52-acre tract. On the remaining 27 acres some recent prospecting has shown a continuation of the sheet orebody. The new company, for which Mr. Bayless will act as manager, contemplates the construction of a 500-ton concentrating-plant.

A group of three new mills is to be found in the West Joplin district, while a fourth has only recently begun operations, thus making this one of the busiest parts of the district. The new plants are the S. Y. Ramage No. 8 and the Once More, both of which are nearing completion; the Gibson Mining Co.'s plant, which is just beginning to produce concentrate; and the A. W. C. Mining Co.'s mill No. 4, which began production about two months ago. The Ramage mill is on a 40-acre lease of the Deering Land & Leasing Co.'s property, one mile west of the city limits of Joplin, and is one of the largest, most modern plants in the entire district, having a capacity of 500 tons per 10-hour shift. The frame is built of structural iron, concrete, and galvanized iron. Gas engines will be used to operate the mill machinery and compressors. Some distance to the east of the mill is a separate unit for the treatment of sludge. This building is as substantially built as is the mill proper, and is equipped with 10 tables. Electric power will be used in the operation of the tables. The Once More mill is on a lease of the Old Hackett Mining Co.'s tract, and a well-built frame mill is nearing completion. On the same ground, but some distance to the northwest, is the new plant of the Gibson Mining Co. This company is working in the old ground formerly mined unsuccessfully by the Hackett Mining Co. An extremely thin, but extensive, sheet-ground formation is encountered at this point, and the new company apparently is making a success out of its venture. The new mill of the A. W. C. company makes the third to be worked by that company. This group is about ¼ mile south of the Ramage, Once More, and Gibson plants. The A. W. C. company's three mills combined make a large weekly production of high-grade concentrate. The average depth of the workings in the West Joplin field is 160 to 170 feet.

A hurry-up job of mill construction is under way at the new plant of E. R. McClelland and J. W. Perry, of Kansas City, who have a lease on 40 acres of the Colclasure land at Porto Rico, Missouri, eight miles northeast of Joplin. They have the ground on which the American Beauty Mining Co. operated five years ago. Sheet-ore is cut at a depth of 200 ft., into which orebody two shafts have been sunk. The mill, costing $37,000, is entirely new. It will be driven by gas-engines and will have a capacity of 350 tons per shift.

C. Clarke and associates of Kansas City, who purchased, through C. W. Edwards, the Spurgeon-Tiger mine on a lease of the Wills & Bucklen land at Spurgeon, 10 miles south of Joplin, are spending $25,000 in re-modeling the mill and installing an up-to-date sludge department. They have three shafts into disseminated ore at a depth of 55 feet.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

The first gold mining in Alaska was in the Juneau district, where operations were begun about 35 years ago. More than $60,000,000 worth of gold has been produced from this area, most of it from the mines near Juneau, which is the most important centre in the Territory. The auriferous belt is, however, known to stretch for about 50 miles to the north and includes the Eagle River region, described in a report by Adolph Knopf, which has been issued by the U. S. Geological Survey as Bulletin 502. This report, unlike many others on mining districts in Alaska, which are of a reconnaissance character, treats of the region in detail. It is entitled 'Geology and Mineral Resources of the Eagle River Region, Alaska,' and is accompanied by a topographic map on a scale of a mile to the inch, with 100-ft. contours, by J. W. Bagley, and a detailed geologic map on the same scale.

The Juneau district was recently visited by Sanford Makeever, who is largely interested in the Alaska Gold Belt property, which is being developed by A. B. Dodd. Mr. Makeever states that it is perhaps not generally known to others than mining engineers that by approaching the upper Sheep Creek district from Grindstone creek it is possible at this time of year, or at a time when there is no snow, to view practically a cross-section of the whole geological formation of the district which comprises the properties of the Alaska Gastineau, Alaska Juneau, and Alaska Gold Belt properties. There are four distinct gold areas near Juneau. The first is the Silver Queen, which ends about where the old sawmill is situated a little below Thane; the second might be called the Perseverance; the third is larger than all of the others combined, but has no name; the Alaska Gold Belt is the fourth area. Its adit will cut the third belt at a depth of about 1200 ft., and, by sinking, a depth of 3300 ft. through both veins will be gained. The Alaska Gold Belt property covers a total of 2690 acres. When the present adit has proved certain orebodies, a 9000-ft. adit, two tracks wide, will be started. At the mill-site 1400-hp. can be developed, there being a 1200-ft. head on Little Sheep creek. A large mill, houses, wharves, and other equipment is to be erected during the next year. A total of about $3,000,000 is to be spent in bringing the property to the producing stage.

VIEW OF THE JUNEAU DISTRICT, ALASKA.

ARIZONA

The itinerary of U. S. Bureau of Mines rescue-car No. 2, in charge of J. H. East, is as follows: Bisbee, September 5 to 7; Clifton, September 7 to 9; Globe, September 9 to 11; Los Angeles, California, September 12 and 13; and San Francisco, September 14.

GILA COUNTY

The Globe-Miami region is in an active and prosperous condition. Many lessees are working, and prospects are shipping ore, in addition to operations at the Old Dominion, Gibson, Arizona Commercial, Iron Cap, Miami, and Inspiration. Three furnaces at the O. D. are producing 50 tons of copper daily, the mill is concentrating 600 tons per day, and the mine output of ore is between 900 and 1000 tons. About 6,500,000 gal. of water is pumped daily. A number of installations are being completed on the surface. Over 10 ft. of high-grade ore has been opened at 1400 ft. in the A. C. mine, the full width not being known yet. No. 10, 12, 13, and 14 levels are active points. There are 120 men employed. The Inspiration Needles Co. has purchased the Prospectors' claims, near the Southwestern Miami. Surface indications of the Inspiration Needles ground are good.

MOHAVE COUNTY

Shareholders of the Union Basin Mining Co., which operates the Golconda zinc mine, 16 miles north of Kingman, received a dividend of $85,000 last week. This is equal to 10% on the issued capital. The daily output of high-grade ore is about 100 tons, mostly from 800 ft. depth.

CALIFORNIA

Final figures of the gold yield of this State in 1914 have been prepared by Charles G. Yale of the U. S. Geological Survey. The total was $20,563,496, the largest output, save 1883, since 1864. The number of metal producing mines was 658, of which 340 were placers that yielded gold and silver valued at $9,100,136. This output from placer mining was $242,590 more in 1914 than in 1913, and was exceeded in 1914 only by that from Alaska. The placers produced 44% of the output of gold from California in 1914, and the 60 gold dredges operated produced 86% of the placer gold and 38% of the gold derived from all sources. The gold recovered by dredging amounted to

$7,783,394, of which the field near Marysville, Yuba county, produced $2,755,734; that near Oroville, Butte county, $1,637,515; and that near Folsom, Sacramento county, $2,161,653. Dredges, operated in Calaveras, Merced, Placer, Shasta, Siskiyou, Stanislaus, and Trinity counties, recovered $1,228,502. Dredge mining was first started in California in 1896 and the total quantity of gold recovered by that method of mining up to the end of 1914 was $71,307,766.

The largest gold-producing centres were Grass Valley (including Nevada City), in Nevada county, where the deep mines yielded $2,997,405 in gold and $25,868 in silver, and the Jackson-Sutter Creek district, where the deep-mine production was $2,113,098 in gold $12,674 in silver.

Nevada county, which produced the most gold, had a yield of $3,301,948, or $383,215 more than in 1913. Other counties that produced over $1,000,000 in gold were Amador, Yuba, Sacramento, Butte, Calaveras, and Shasta.

The total value of the mine output of gold, silver, copper, lead, and zinc was $25,710,645, so that the value of the gold recovered amounted to 80% of the total value of the five metals. The mine productiou of copper was 30,507,692 lb., valued at $4,057,523; silver, 1,471,859 oz., $813,839; lead, 4,251,923 lb., $165,825; and zinc, 389,471 lb., $19,863. The total quantity of ore sold or treated in 1914 was 2,465,485 tons, and the average value per ton of all metals recovered was $6.74. Of the ore treated, 2,050,3337 tons was silicious gold ore, from which there was an average recovery of $5.25 per ton in gold and silver. There was 1,993,821 tons of ore treated at gold and silver mills, which yielded $10,743,207 gold and $91,327 silver, or an average value of $5.44 per ton. Ore smelted amounted to 449,132 tons, of which 397,868 tons was copper ore, 640 tons lead ore, and 16,180 silver-lead ore. This smelting ore yielded metals valued at $5,633,856, or an average of $12.54 per ton.

Shasta county was the largest producer of copper, with an output of 25,198,669 lb., and it also made the largest production of silver, 626,954 oz. Inyo county supplied all the zinc, and 4,205,154 lb. of lead out of a total State production of 4,251,923 lb. The most productive metal centre in the State was at Kennett, in Shasta county. From the mines at and near Kennett there were recovered metals valued at $3,087,279, of which $2,411,323 was for copper.

Oil production of the State in July totaled 7,738,643 bbl., an increase, according to the Independent Oil Producers' Agency. Ten rigs were completed, 132 wells were drilling, 36 wells were completed, 19 wells were abandoned, and 6083 were producing.

In view of the great interest manifested by first-aid teams from mining colleges in the third annual joint field meet to be held by the U. S. Bureau of Mines, the American Mine Safety Association, and the California Metal Producers' Association in San Francisco, September 23 and 24, the rules committee has withdrawn the restrictions against the participation of such teams in the meet. The ruling previously made that only teams from bona fide mining, smelting, and milling operations should be admitted to the interstate contests of September 24, thereby restricting teams from mining colleges to participation in the demonstrations of September 23, has been modified to provide that such teams and teams from state departments or other institutions interested in safety in mining, but not concerned in mine operation, may compete among themselves on the 24th for a special prize for the most proficient team from an educational institution. It is hoped that a special prize or cup may be offered as an award to the team winning in this special competition. It is believed that this modification of the rules governing the meet will result in the sending of a good number of teams from the various colleges and universities in the West.

Eldorado County

Sampling of the Georgia Slide mine is in progress for New York people. M. L. Hurley is in charge of the work.——At Clarksville, in the extreme west of the county, G. S. Miliken of Sacramento is developing a rich prospect. A two-stamp mill has been erected to crush the ore.——The Stillwagon mine, southwest of Placerville, is being re-opened by G. Willis. The property has produced a good deal of gold, being opened by a 790-ft. adit and other workings. A five-stamp mill and general equipment is being overhauled.

Inyo County

(Special Correspondence.)—The Skidoo Mines Co. has been operating 15 stamps with considerable difficulty. The 24-mile pipe-line, which serves for both power and water-supply, developed many weaknesses during the hot weather. The company is considering installation of a 40-hp. gas-engine for auxiliary power.——A. Murphy, Jr., lease on the Cashier mine at Harrisburg will be closed in a few weeks. All the ore appears to have been extracted.——The antimony mine at Wild Rose is keeping five 2½-ton motor trucks busy hauling ore to Trona. The tonnage was recently increased by the addition of a Renard train, originally imported from England by the American Trona Co. The train made the first 45-mile trip successfully with 15 tons. The antimony occurs as stibnite in lenses scattered over eight claims. The ore is high grade, and remarkably free from gangue minerals. The gossan minerals are senarmontite and cervantite. The small smelter in which the sulphide ores were treated was a failure, the building now being used for a machine-shop.——A small quantity of zinc ore is being hauled to Trona from the old Minietta mine, which adjoins the Modoc of Haggin fame.

Skidoo, August 24.

The Cerro Gordo mine is employing over 140 men and producing about 140 tons of zinc ore daily, in charge of Louis D. Gordon. A total of 1681 tons of ore was mined from the 200, 400, and 500-ft. levels during March, April, May, and June. This contained 1,109,481 lb. zinc. The mine has been opened to 1200 ft. depth. Of importance to the district is the Troeger adit, which has been driven over 6000 ft. to cut the veins in Cerro Gordo hill. A high-grade silver-lead vein has been cut, also several containing copper and gold. The adit is being extended.

Placer County

The Dewey Consolidated gravel mine, adjoining the Morning Star, at Iowa Hill, is being developed by J. P. Keene.

Plumas County

The Plumas Eureka Mines Co. of Johnsville is bankrupt with $133,634 liabilities and $41,515 assets.

Tuolumne County

(Special Correspondence.)—From the clean-up of 15 stamps for the last half of July, the Nyman Consolidated company shipped two bars of gold-bullion weighing 251 oz. One bar is from the Knox & Boyle claim, which is being worked by lessees. About three months time has been spent in unwatering the Knox & Boyle shaft, and in making repairs to the track and clearing portions of the deeper development after remaining dormant for about 15 years. The shaft has been opened to the 800-ft. level, but at 700 ft. a good orebody was found showing 4 to 6 ft. This ore has averaged about $10 per ton recovery in the last month, and with the entire south face of the stope between the 700 and 600-ft. levels in good milling ore, the lease should prove profitable. Twenty-five per cent royalty is paid, plus $1 per ton for milling by the company. Work is being carried on in two shifts, with four machines in operation in the stopes. The second bar is from a short mill run on the Mascot ores now being mined on the 200 and 250-ft. levels of the East vein in the Miller & Holmes claim, and comes from the ores left in the stopes by the 'gopher-holers' last in operation, and now necessary to remove before any practical mining is possible. This ore so far extracted has shown to the management that a good return could be secured from its treatment in the mill, and over 500 tons have been sent to the mill to date.

Jamestown, August 9.

IDAHO

Elmore County

The Rocky Bar property, in the district of that name, is being worked by W. D. Ebbert, of Salt Lake City. He contemplates erecting a 100-ton mill. The mine is opened by adits.

Shoshone County (Coeur d'Alene)

Dividends paid in eight months of 1915 are as follows:

Company	August	8 months
Bunker Hill & Sullivan	$ 81,750	$ 654,000
Caledonia	78,150	468,900
Federal	.....	240,000
Hecla	70,000	180,000
Hercules	.....	1,000,000
Interstate-Callahan	920,000	1,610,000
Stewart	.....	681,098
Success	120,000	285,000
Total	$1,269,900	$5,118,098

On September 4 the Bunker Hill & Sullivan company will pay dividend No. 215, amounting to $81,750. This makes a total of $16,446,000.

The Black Bear Consolidated Mining Co., which has been developing the Black Bear mine, near Gem, has been absorbed by the Rex Consolidated Mining Co., recently organized to take over the Rex mine, in the Nine Mile district of the Coeur d'Alene.——A report made on its mine by C. F. O. Merriam has been published by the Nabob Mining Co. The main adit is in 1964 ft., and a total of 3037 ft. of development has been done. The engineer recommends that the ore exposed (20,000 tons) in the upper workings and in the lower adit be further developed. This can be done without any extensive work, a total of about 1405 ft. Electric power and a larger compressor are necessary. Development should then be about $14 per foot.

Owyhee County

The Chicago Nitrate Co. has reduced its force to seven, while waiting the result of pending suits to determine whether the claims must be located as quartz or placer. Most of them were located as quartz claims.

MICHIGAN

The Copper Country

During the half-year ended June 30, 1915, the Quincy Mining Co. paid $666,250 in dividends and for land purchased, $226,250 being paid the Hancock company under an agreement several months ago. This gives the Quincy important privileges. In 10 years the Quincy company has paid $1,746,250 for land acquired.

Seventy feet of the No. 2 shaft of the Centennial, which was burned two weeks ago, is to be re-timbered. When the skip dropped, it tore out a good deal of timber lower down. Most of the wood on the rock-house will have to be replaced. Breakers and shafting were little damaged.

Isle Royale is shipping from 2500 to 2700 tons of ore daily to the mills; Mass is producing about 1200 tons per day; and Superior about 500 tons.——South Lake will soon be able to send over 400 tons per day to the Franklin mill.——Over 250 men are working at the Lake.——The Ahmeek output is over 2800 tons per day, also a good deal of mass copper.——It is reported that tailing from the White Pine mill contains 12 to 15 lb. copper per ton, so they are being stored for future treatment. Transport of 'mineral' (concentrate) from the mill to the C. & A. smelter at Hubbell is difficult and expensive. No. 4 shaft is down 912 feet.

As the Copper Range subsidiary companies each pay Federal income-tax, a total of 3% on the gross income, all the companies are to be consolidated, the Copper Range having increased its capital from $2,500,000 to $10,000,000, divided into 400,000 shares at $25 each.

MISSOURI

Jasper County

Low prices and rain interfered with good returns in the Missouri-Kansas-Oklahoma district last week. The output was as follows: Blende, 4846; calamine, 284; and lead, 944 tons, averaging $50.72, $38.54, and $43.84 per ton. The total value was $298,498, and for 34 weeks, $14,852,149.

MONTANA

Silverbow County

At the Anaconda mine, a concrete building to contain mine-rescue and fire-fighting apparatus, also to serve as quarters for training in rescue and first-aid, is being constructed. The Leonard and Original mines' first-aid teams will compete at Butte on Labor Day for the honor of representing the district at the contests at San Francisco in two weeks' time.

At 2500 ft. in the Davis-Daly the southwest cross-cut has cut No. 1 branch of the Hesperus vein.——An option has been acquired by the East Butte company on 18 acres of the Largey estate adjoining the Davis-Daly for $200,000.

NEVADA

The production of gold, silver, copper, lead, and zinc from Nevada ores sold or treated in 1914, according to Victor C. Heikes, of the U. S. Geological Survey, was valued at $29,300,842. Details are as follows:

Gold, ounces	555,402
Silver, ounces	15,455,491
Copper, pounds	60,986,450
Lead, pounds	12,809,655
Zinc, pounds	12,980,232

There were 731 producers of these metals during the year. Of the total of 4,522,022 short tons of ore sold or treated, 1,461,577 tons was treated in gold and silver mills, principally cyanide; 2,768,193 tons was concentrated, largely copper ore; and 261,018 tons represented crude ore that was shipped to several smelters. The largest part of the total tonnage, or 2,882,121 tons, represented copper ore; 1,594,486 tons was silicious ore; 16,088 tons lead ore; 9490 tons zinc ore; 3762 tons copper-lead ore; and 16,075 tons lead-zinc ore.

Esmeralda County

A Cameron motor-driven pump of 150-gal. capacity per minute has been ordered by the goldfield Great Bend company. This will be installed at 400 ft. The present flow of water is 75,000 gal. per day, but it has been as high as 200,000 gal.——Final figures of July operations at the Goldfield Consolidated are as follows: mine development, 2557 ft., at $5.97 per foot; ore treated, 33,388 tons, realizing $105,292 net; net costs, $4.91 per ton; and lessees' production, 1588 tons with a gross value of $45,436, from which the company received $17,962, less the cost of milling and transportation. On October 31 a dividend of 10c. per share will be paid.

Humboldt County

(Special Correspondence.)—A hoist, pump, and other equipment is being installed at the old Nelson copper properties on Jackson creek in the Jackson mountains. H. D. Bemis is superintendent. Bids are wanted for hauling 500 tons or more ore to the railroad. The distance is about 38 miles, two miles down a good canyon road from the mine to the desert, and then about 36 miles of good desert road to the station of Sulphur on the Western Pacific line.——DeVoe and Curry have just dispatched some 25% copper ore, and several other shipments have recently been made from the old camp of Red Butte.——Lessees are preparing to extract ore from the old Champion copper claims belonging to W. E. Christiernsson.

'On the Copper' via Sulphur, August 28.

The Friedman adit at Rochester is in over 650 ft., the present advance with three shifts being 18 ft. per day. The country is rhyolite that breaks well.——At the Foreman lease 300-

ft. level they are driving north from the transportation adit. This lease made a shipment of 40 tons, stated to be the richest average lot extracted from Rochester hill for a similar tonnage, being about $60 per ton. This syndicate will declare a $1500 dividend. It has only been operating since about the first of August.——The president of the Nevada Short Line railroad, A. A. Codd, announces that the track is now laid to the foot of the Rochester Mines tramway and the portal of the Friedman adit, and that he should be able to contract for hauling ore next week. The new Shea engine has been repaired. He has ordered another 30-ton Shea for immediate delivery. Several air-brake ore-cars of 25-ton capacity are to hand. Although present requirements call for about 125 tons of ore to the mill each day, the road will be able to transport 500 tons.

LINCOLN COUNTY

A 50-ton plant to use water concentration and flotation has been definitely decided for the Amalgamated Pioche company. The General Engineering Co. of Salt Lake City tests showed that two products could be made, namely, a 40% zinc concentrate with some gold and silver, and an iron concentrate high in gold and silver but low in zinc. A contract for the sale of this material has been made with the U. S. Zinc Co., a subsidiary of the A. S. & R. Co. Development at 1400 ft. in the mine is very satisfactory. About 12,000 tons of milling ore is on the surface, and over 20,000 tons is opened underground.

LYON COUNTY

Six sets of lessees are busy at the Empire-Nevada Copper Co.'s property, two miles from Yerington. Good ore is being extracted.——On August 26 the nitric acid plant at the Nevada-Douglas mill started work. Ore was crushed on the 30th, and the digesters are ready to commence.

NYE COUNTY

Tonopah activities during the past-week were as follows: Five mines and lessees produced 10,098 tons of ore valued at $207,724.——On October 1 the Belmont will pay its quarterly dividend of 12½%. The rhyolite vein at 1100 ft. has improved in width and value.——At 700 ft. in the Jim Butler the south vein is opening well.——The Extension will pay a 7½% dividend on October 1, a total of $95,430. July profits were $34,847. The 1350-ft. level is opening better than at the 1260-ft. level.——In the Mizpah mine of the Tonopah company, a block of unknown ore has been found just below the 500-ft. level.——At the Montana there are 45 men working on leases.——Exploration continues at the Mizpah Extension, North Star, Halifax, Rescue-Eula, Bonanza, Umatilla (diamond-drill at 1500 ft.), Monarch Pittsburgh, Cash Boy (6 in. of $26 ore cut at 1450 ft.), Gipsy Queen, and Buckeye-Belmont.

At the Round Mountain placer claims the first clean-up yielded about $15,000. This is only from 40 to 80% of the gold in the sluice-boxes. Profits are large.

STOREY COUNTY

At 2500 ft. in the Union mine quartz has been cut for 17 ft. width, 6 ft. of which assays $40 per ton, the remainder being of fair value.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—Mining at Magdalena shows considerable activity. The older mines are being operated full time.——A test shipment of ore was recently sent to the El Paso smelter by the Hop Canyon Mining & Smelting Co. Returns show 12.9 oz. silver and 7.02% copper. This company is completing a 1500-ft. adit, and expects to soon make large and regular shipments.——The Wheel of Fortune, adjoining the above on the south, has lately developed a five-foot vein of high-grade copper ore.——The Black Cloud mine, recently purchased by Wolf & Moore, is now shipping 120 tons of zinc sulphide per week. New hoist and machinery is being installed there.——The Calumet-New Mexico Mining Co. and others are hurrying development with a view to early shipments of copper-silver ores.

Magdalena, August 23.

The construction of a highway between the Clifton-Morenci district of Arizona and the Mogollan district of New Mexico has often been advocated. The manager of the Mogollan Mines Co., S. J. Kidder, states that the company pays about $47,000 per year for haulage of supplies. Other companies also spend large sums. The present route is unsuitable. The companies are agreeable to discuss the matter with the Greenlee County Chamber of Commerce.

TEXAS

ARCHER AND YOUNG COUNTIES

(Special Correspondence.)—Experiments that T. S. Lessohn has been making to separate nodules of copper from the extensive claybeds in these counties are reported to be very satisfactory. The copper-bearing material is dried, the clay passing off as dust. It has long been known that the copper deposits of this region were rich, but the difficulty that prevented its earlier development was that of extracting the copper nodules from the clay. The late General McClelland headed an expedition in the early seventies that had for its purpose the opening of these copper deposits on a large scale. Over $500,000 was spent by him on that one investigation. He shipped considerable quantities of the material to Philadelphia, but it was found that the cost of mining was too great to be profitable.

Alpine, August 17.

BREWSTER COUNTY

(Special Correspondence.)—It is reported that the Chisos Mining Co., which has been profitably operating a quicksilver property in the Terlingua district for several years, about 90 miles south of Alpine, will install a new 40-ton furnace. The district output of mercury should be a considerable increase over that of last year. Several people recently visited the district and are said to have obtained options upon the more promising properties. Mexican prospectors recently reported the discovery of cinnabar outcrops in the rough country on the opposite side of the Rio Grande from Terlingua, but it is not expected any effort will be made to develop the deposits in Mexico until that country is settled.

Alpine, August 17.

CULBERSON COUNTY

(Special Correspondence.)—An option has been obtained on part of a large sulphur deposit by T. L. Todd of Houston and associates. If the pending transaction is completed they will install machinery and develop the property on an extensive scale. There is a large quantity of sulphur on the surface. The fact that the deposit is remote from railroad transportation has heretofore prevented its exploitation. It is claimed that the mineral is of high grade and can be mined at low cost.

Houston, August 17.

HAYS COUNTY

(Special Correspondence.)—While prospecting for gold and silver in the hills near the head of the San Marcos river, a few miles from San Marcos, C. D. Griffin discovered a large outcrop of lead-zinc ore. Assays are satisfactory. Preparations are being made for development of the property. The discovery is in the central part of the State, more than 100 miles from the Llano district, where the nearest precious minerals are found.

San Marcos, August 17.

UTAH

In the second annual mine-rescue and first-aid contest at Castlegate, Carbon county, on August 21, the Sunnyside team defeated five other teams with 97.5%. These men will go to the national contest at San Francisco. The meet was held under the auspices of the Utah Fuel Company.

Juab County

On August 26 the hoisting-plant at the Victor Consolidated was destroyed by fire. The blaze started at 300 ft. depth and burned the shaft-timber to the surface. Lessees were working at this level.——At 1780 ft. in the Eagle & Blue Bell, ore is showing for the full width of the drift.——The new plant of the Utah Minerals Concentrating Co. treated about 1000 tons of ore in 30 days. Part of this is from the Chief Consolidated. Concentrate assays 51% lead and 13 oz. silver per ton. The mill was erected to treat the low-grade ores of the district.

Salt Lake County

A 200-ton mill to treat ores from the Cardiff and other mines in the Alta-Big Cottonwood area is probale, according to Ezra Thompson of the Cardiff company.

During the quarter ended June 30 the Utah-Apex company made a net profit of $72,154. Gross receipts totaled $233,821. The Parvenu shaft was sunk to 1300 ft., and the cross-cut at that depth should soon cut the vein. A considerable amount of development was done. A flotation process is being installed at the mill. On October 1 a dividend of 12½c. per share will be paid.

Summit County

At the Broadwater Mills 500-ton plant at Park City 100 men are busy on construction. Treatment should commence in about two weeks.

Summit County

A contract has been let by the Daly-Judge company to the Allis-Chalmers company for a hoist of 2700-ft. capacity. The average speed will be 1200 ft. per minute, the machine to be driven by a 400-hp. motor with 1000-hp. starting duty. A new steel head-frame and other equipment is being installed. The manager of the Daly-Judge, J. W. Lambourne, has let a contract for 2000 ft. of additional work in the Snake Creek tunnel.

In *Economic Geology* for April-May the Tintic district is discussed by Waldemar Lindgren. An abstract will appear later.

WASHINGTON

Spokane County

The Spokane Chamber of Commerce is collecting statistical data for a new handbook on mining in the Northwest. County officials in the states and recorders of the provinces of Canada have been asked to supply lists of the live mining properties in their territories. Considerable data have already been received. Information is being secured from the states of Montana, Idaho, Oregon, and Washington, and from British Columbia and Vancouver Island. The information will be compiled by the statistical department and issued under the title of the 'Northwest Mining Handbook.'

Stevens County

The Northport smelter is being re-modeled. Furnaces No. 1, 2, 3, and 4 are to be dismantled, and No. 5 and 6 are to be used for the treatment of copper ore. Lead furnaces are to be installed.

Improvements and additions to the mill at the United Copper mine near Chewelah, Wash., have been completed, and the entire plant now in operation, according to Conrad Wolffe of Spokane, president and general manager. Flotation is employed. Seventy men are working.

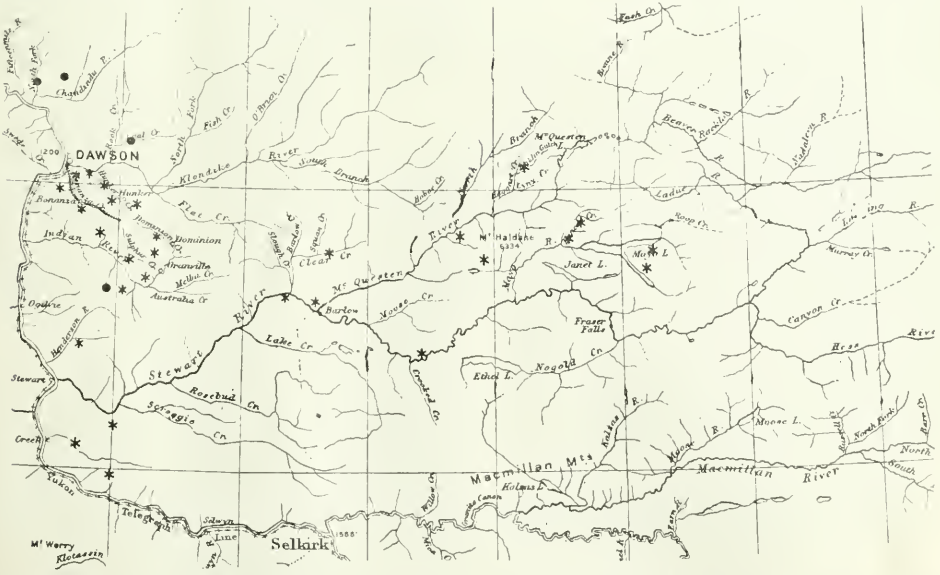
CANADA

Yukon

A geological examination is being made of the Mayo district by D. D. Cairnes and W. Cockfield. The silver-lead mines on Galena creek will be included in the reconnaisance work, a detailed investigation to be made next season.

British Columbia

The Rocher de Boule Copper Mining Co. in July shipped 3000 tons of ore assaying 9% copper and $2.50 gold and silver to the Granby smelter at Grand Forks. The mine is near Hazleton. The ore was extracted from above 350 ft. Deeper development is opening ore of equal value. The profit in July was $50,000. J. F. Cowan of Salt Lake City is president of the company.



PART OF THE YUKON TERRITORY SHOWING THE MAYO DISTRICT. THE M'WHORTER LEAD MINE IS ON GALENA CREEK, A TRIBUTARY OF THE NORTH FORK OF THE M'QUESTEN RIVER. THIS PART OF THE COUNTRY IS THE HEADWATERS OF THE RIVER. ORE IS HAULED 30 MILES TO MAYO LANDING, THEN DOWN THE STEWART RIVER, UP THE WHITE PASS RAILWAY TO SKAGWAY, AND THEN DOWN THE PACIFIC COAST TO SMELTERS. THE STARS REPRESENT GOLD DEPOSITS.

Dividends paid by companies in this province in 1915 are as follows:

Mine.	August.	8 months.
Granby	$225,000	$225,000
Canadian Consolidated	116,088	232,176
Hedley	.....	120,000
Le Roi No. 2	.....	28,800
Total	$341,088	$605,976

On September 10 the Standard Silver-Lead company will pay 2½c. per share, equal to $50,000. Equal monthly dividends are expected from now on. The total is $1,600,000. Lead concentrate goes to the Trail smelter, the settlement being 5c. per lb. for lead, and a charge of $8 per ton for freight and treatment. Zinc concentrate is being stored. About 100 men are employed. The flotation plant is working well.

The Slocan Star, near Sandon, is treating about 120 tons of ore per day of 22 hours. This yields 300 to 350 tons of zinc-silver and 125 to 150 tons of lead-silver concentrates. Sixty men are employed. On No. 4 level 45% zinc ore has been opened. The mine has about 6000 ft. of workings.

KOREA

On July 31 the Oriental Consolidated distributed 50c. per share. This is No. 30.

On account of floods the July output of the Oriental Consolidated was only $97,500.

MEXICO

Hidalgo

The Santa Gertrudis Co. reports that in June the mill treated 14,066 tons of ore yielding a profit estimated at $23,000.

Jalisco

According to Makeever Bros., of New York, the last letters from their El Favor property were on June 6. It was then stated that cyanide precipitate worth $13,000 was stolen, and Stephen Parmenter, of Los Angeles, was killed by bandits who attacked the bullion train. This was guarded by soldiers who disappeared when the attack was made.

Sonora

General P. Elias Calles, Carranza commander of Sonora, has closed all saloons in Nacozari and Cananea. August payrolls at the Moctezuma and Tigre mines and mills will be on a silver basis. Out of about 16,000 tons of concentrate stored at the Moctezuma mill about half has been sent to Douglas. All concentrate has been shipped from the Moctezuma mill to Douglas, a total of 444 cars.

According to the *Douglas Daily Despatch* of August 30, Governor Maytorena, the Villa chief, will relinquish the office of governor of Sonora on September 15, as announced from his office. Albert Morales, now state councillor in Maytorena's cabinet, will become governor. General Felipe Angeles, who is reported to be on his way from Chihuahua with 3500 men, will assume the military chieftainship on behalf of the Villa states of Sonora and Sinaloa. The report that Villa had been assassinated was denied by Maytorena, who received a telegram from Villa. The advent of Angeles into Sonora is being watched with great interest as to the possibilities of his making a strong showing in the State. Confirming the reports of the coming of the former Madero-Carranza-Villa leader into Sonora, Maytorena officials are still reticent as to the extent of the movement and what it will mean to the State. Carranza officials have reports that Angeles is coming to Sonora for the purpose of disavowing Villa, and in all probabilities attempting to turn the State into a new political unit, not embracing the Carranza or Villa cause, but rather the element who are now exiles, composed of old federals.

Final figures of the gold and silver output of the United States in 1914 will be published in full next week. The gold yield was 4,572,976 oz., and silver, 72,455,100 oz., both increases.

PERSONAL

George Watkin Evans is in Alaska.

Charles W. Morse is here from Butte.

Jas. W. Abbott, of Los Angeles, was here this week.

Horace V. Winchell was at Grass Valley during the week.

A. J. McNab of Thompson, Nevada, is visiting the Exposition.

F. Lynwood Garrison is expected here from Tuscon next week.

D. B. Donovan has gone from Johannesburg to Tarkwa. West Africa.

P. D. Burtt is at the Nevada Packard mine, near Rochester, Nevada.

W. Ingham has been elected president of the South African Institution of Engineers.

J. W. Hutchinson and A. H. Howe of the Goldfield Consolidated are at the Palace Hotel.

L. C. Graton is in Shasta county, engaged in geological work for the U. S. Geological Survey.

R. T. Walker has been appointed superintendent of the Techatticup mine, at Nelson, Nevada.

J. M. Callow of Salt Lake City passed through San Francisco on a motor tour through California.

John W. Finch and W. H. Wiley have been in San Francisco in connection with mining litigation.

G. M. Butler has been appointed Dean of the College of Mines and Engineering in the University of Arizona, at Tucson.

F. L. Sizer will be in San Francisco for the engineering conventions, having been appointed a delegate by the Governor of Arizona.

E. V. Bray, mill-superintendent of the Exploratie en Exploitatie Maatschappiji Bolang Mongondon, Goervepalej, North Celebes, Dutch East Indies, arrived here on the *Mongolia*. He returns on the *Shinyo Maru* on November 20. The company is operating an all-sliming plant. During 1916 the company expects to begin construction of a new mill on the Minto concession, 10 miles distant from its older property.

Schools and Societies

The University of California reports that there are 1517 freshmen attending this fall, larger than in 1914. For engineering there are 160 against 184. The present national unwillingness to engage in new engineering construction is thought by the University to be the explanation. Of the 160 engineering students in this year's freshman class, 95 are in mechanics and electrical engineering, 46 in civil engineering, and 19 in mining. The total registration of all students is 5407, which is nearly 300 more than this time last year, and the year's registration in all departments, including the summer session, will exceed 11,000.

The American Mine Safety Association of Pittsburgh, Pennsylvania, states that the impression seems to have been conveyed by articles appearing in some technical journals that the Association has ceased to exist. According to the president, A. F. Knoefel, and the secretary, H. M. Wilson, this is not so; on the contrary, it is not only very much alive but will be more active than in the past, though under another name. The recent ballot concerning the amalgamation with the National Safety Council was almost unanimously in favor of such action, and the executive committee of the latter also favors the taking over of the American Mine Safety Association as its Mining Branch. The effect will be to practically centralize all safety movements within the National Safety Council. The American Mine Safety Association will hold its annual meeting as contemplated at Birmingham, Alabama, on September 3.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, September 2.

Antimony	35 —35¾
Electrolytic copper	18½—18¾
Pig lead	5.15— 6.10
Quicksilver (per flask)	$95
Spelter	17 —17¼
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	30

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, September 2.—The copper market is easier, with buyers reserved; lead is quiet, and not quite so firm; the zinc market is uncertain.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	13.60	19.75	Dec.	12.75	....

Exports during the week ended August 14 totaled 13,927,812 lb., valued at $2,586,788. Russia in Europe absorbed 3,697,945; France, 3,199,047; England, 2,574,752; Russia in Asia, 1,792,392; Italy, 1,390,429; and Denmark, 1,008,524 lb. Imports of all kinds of copper metal totaled 7,246,671 lb., worth $1,021,507. Of this, 2,271,861 came from Peru, 1,102,000 from Brazil, 1,413,365 from Cuba, and 1,988,999 lb. from Canada.

Exports during the fiscal year ended June 30, 1915, totaled 677,303,822 lb., valued at $96,238,800, against 974,791,676 lb. worth $144,895,519 in the previous period. Germany showed a decrease of 281,000,000 lb., and England and Italy increases of 88,000,000 and 55,000,000 lb. respectively.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Aug. 26	46.75	July 21	47.47
" 27	47.12	" 28	47.29

June	56.43	49.03	Dec.	49.27	....

The financial situation in England, the low rate of exchange, probably accounts for the record low price of silver. On August 25 about 160,000 oz. was sent from San Francisco to China. London stocks are estimated to exceed 19,000,000 oz. Exports from London to the Orient to August 11 total £4,496,500, against £3,031,250 in that period of 1914.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

Final figures of the quicksilver production of the United States in 1914 show a total of 16,548 flasks, valued at $811,680, according to the Geological Survey. This is a decrease of 3665 flasks. California yielded 11,303; Nevada, 2089; and Arizona and Texas, 3156 flasks, the last three States showing increases.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

The rise in spelter had its effect on prices of ore in the Missouri-Kansas-Oklahoma region last week. The average was $18.50 higher. The output was as follows: blende, 4678; calamine, 308; and lead, 967 tons, averaging $72.68, $47.20, and $43.84 per ton respectively. The total value was $396,861; 35 weeks, $15,249,010.

ALUMINUM

A steady demand, a good part of which has been for export, is responsible for aluminum being quoted at 34 to 35c. It would require but little pressure to send the market to higher levels.

ANTIMONY

There has been some good inquiry with considerable resultant business in antimony, but comparative offerings have brought the quotation for Chinese metal down to 28c., duty paid.

Eastern Metal Market

New York, August 27.

The long expected turn in copper, lead, and zinc came along two days ago, but how substantial it will prove to be remains to be seen. The facts at present are that copper has advanced from 16 to 18c. per pound, lead has gone up $8 per ton, and zinc has increased nearly 4c. per pound. All this took place between August 24 and 27. Of course, the cry of manipulation has been raised, but it cannot be disputed that large quantities of all three metals have changed hands, with buying on both foreign and domestic account. On August 24 all the indications were for a runaway market in lead, while copper was nearly as excited. The rise in zinc was more rational in that it started earlier. Tin has advanced 1c. per pound, more because of strength in London rather than by reason of buying here. Under pressure to sell, Chinese antimony has declined and is now quoted at 28c., duty paid. Aluminum is strong and quotations have been well sustained.

The exchange rate for the English pound sterling was down to $4.63\frac{3}{4}$ on August 26.

Quotations for semi-finished and finished steel products have continued to advance. For plates, shapes, and bars the general quotation is now 1.35c., Pittsburg. Billets are exceedingly scarce, and prices have soared to such an extent that manufacturers see a better profit in selling unfinished steel than in rolling certain products. Shrapnel and high-explosive shell-rounds are selling at around 3c. per pound, or about twice what can be obtained for ordinary products. A result of the high prices obtainable for steel has caused steel-making iron to be sharply advanced; while foundry irons are advancing also; in fact, too rapidly in the judgment of many, inasmuch as the foundries in some parts of the country are not yet busy. Exports of steel are heavy. The demand for shell and rifle-making machinery shows no abatement.

COPPER

After 10 weeks of dullness, accompanied by declining quotations, the market took a sudden and, in some respects, unprecedented, turn on August 24. Up to noon on that day electrolytic could be procured easily at 16c. cash, New York. Late in the day 17c. was asked, and the following day second-hands were asking 17.50c., while producers were asking 18c. With the change the market became excited. There was some large buying, credited to a desire on the part of ammunition makers to provide for their future needs. There could have been still more business had not sellers shown a disposition to withhold from selling, a move which not only restricted business, but added greatly to the uneasiness of consumers. Inquiries poured into the market. Prior to the change which came over the situation there was some forecast of what was coming, in the desire of second-hands to buy, provided they could get the metal at a shade under 16c. Needless to say, they do not buy unless their judgment tells them the time is ripe to buy for a future profit. It yet remains to be seen how far upward the present trend will carry the market; something which is extremely uncertain in view of the conflicting rumors which are afloat. It is alleged on one side that the market has been manipulated to bring about an abrupt advance, and on the other that it had been unduly depressed by foreign influences traceable to Great Britain's desire to buy cheap copper. For weeks prior to the jump in prices it had been reported almost daily that large export buying was imminent, but the trade had been so regularly disappointed that it began to view the reports lightly. On August 25, the day following the sudden hardening of the market, the London price of electrolytic advanced £1, and the following day £4 10s. more. At the same time, despite the London movement, the price there was still £4 below New York parity. On August 27, second-hands were quoting (New York) 17.50 to 17.75c., and producers 18 to 18.50c. On the strength of the higher quotations copper wire was advanced 1c. per pound to 18.50c. base. With all the activity, the fact remains that commonplace consumption of copper is not yet normal, while it also is true that the exports of ingot copper have been light. Up to August 28, exports totaled only 14,215 tons. The consumption for war purposes is heavy enough to fill some departments of the mills to capacity, but the trade insists that this demand is not sufficient to offset the falling off in other directions. Lake copper, up to the turn, declined with electrolytic, choice brands having been sold at 19c., and less favored brands at less. The premium for Lake has practically disappeared at the present time.

ZINC

About August 20 a demand appeared for spelter. It was not spasmodic, but steadily increased in volume, until by August 25 the market was not only active, but excited, a condition which sellers helped along by appearing not overwilling to sell. The quotation on the 20th was 11.25c., New York, but by the 26th it had reached 14.75c., and was firm at that figure, although the buying showed signs of tapering off. On the 27th the New York price for prompt went to 16c. Consumers have become more wary. Up to the beginning of the advance brass-mill special has been held at 15c., and choice brands at 35 to 40c., although little business was done at the latter high prices. Producers of the A-1 grades were sold up, and simply had no reason to quote less than they did at the end of the big advance of a few weeks ago. When the market became active last week, European as well as home consumers came into it strong. An indication of the uncertainty of the market lies in the fact that on August 23, sheet zinc was reduced 2c. per pound to 15c., f.o.b. mill, whereas on the 24th it was advanced to 16c. Exports of spelter from August 1 to 28 totaled 3589 tons.

LEAD

Late on Tuesday, August 24, buyers came tumbling into the market, and for a time it looked as if the wild days of early June, when the New York quotation went to 7c. and over, were to be repeated. There was every indication of a runaway market. Sellers went home that night with orders for thousands of tons left unfilled. Next day the A. S. & R. Co. advanced its New York quotation 10 points to 4.60c., in which it was followed by independent sellers. The scramble to buy was not checked to any great extent, however, and the following day the leading interest raised its quotation another $2 per ton, or to 4.70c. On the 27th this concern advanced its price again, from 4.70 to 4.90c., or $4 per ton. Dealers showed their confidence in the market by seeking to buy on the rise at 2 to 5 points over the prevailing price. The fact that many were burned in the previous frantic flurry of buying seemed to have been entirely forgotten. The exports, August 1 to 28, totaled 1958 tons.

TIN

Except for one or two periods when there was a fair activity on the part of small consumers of tin whose buying was largely confined to lots of 5 to 15 tons, there has not been much doing. In London there has been a marked improvement in the metal, and this has been reflected here; that is, so far as prices are concerned. On August 24 the New York quotation was 33.75c. for spot metal, whereas on the 26th it was 34.75c.

BOOK REVIEWS

Petroleum Technologists' Pocket-Book. By Sir Boverton Redwood and Arthur W. Eastlake. P. 454. Ill., index, also colored plate and 8 maps. Charles Griffin & Co., London, and J. B. Lippincott Co., Philadelphia, 1915. For sale by the Mining and Scientific Press. Price, $3.

In spite of the War, petroleum production of the world in 1914 showed an increase of approximately 15,000,000 bbl., the total being 400,483,489 bbl. Of this the United States yielded 66.36%, and accounted for most of the gain. Russia and Mexico produced 16.74% and 5.29% respectively. The oil business has suffered from over-production and lack of business, while enormous stocks are on hand. Yet the search for oil-bearing areas continues. The little maps accompanying this pocket-book show where every known deposit in the world is situated. Part I of the work briefly describes the deposits so marked, prospecting for oil, and acquisition of oil lands. Some geological notes are given in the next section, including monoclines, anticlines, and synclines, all important to the oil geologist and driller. The physics and chemistry of oil covers 106 pages, including the yield of products of crude oils throughout the world. The chapters on production (drilling methods); refining, transport, storage, and testing; and uses of petroleum and its products is discussed concisely and in an interesting manner. A useful lot of statistics and miscellaneous data completes a handy little book which all petroleum engineers should have with them in the field and office.

Twenty-Fifth Annual Report of the Transvaal Chamber of Mines, for the Year 1914. P. 472. Index, and large map of the Rand. Argus Printing and Publishing Co., Ltd., Johannesburg, 1915.

Importance of the Transvaal as a gold-producing country is well shown at the Panama-Pacific Exposition by large spheres and an obelisk, by which its proportion (38.3%) of the world's yield is noted. The contents of the annual report of the Chamber of Mines also show the extent of the industry. Seventy-four large companies comprise membership of the Chamber, and during the year the various committees dealt with native labor, recruiting, and grievances, health conditions at the mines, mining education, work of the central buying committee, disposal of gold, legislation including miners' phthisis, workmen's compensation, taxation, patents, water supply, and many other matters of importance. The Witwatersrand Native Labor Association's report covers 45 pages. There were 213,829 natives recruited at a cost of £134,466. The revenue from fees on natives distributed was £259,158. The profit (a refund) was £90,719. At the end of 1914 there were 176,105 natives and 21,875 whites employed at the gold mines. In 1914 there was an average of 6247 machine-drills operated. An average of 9.68% of waste was sorted from the material mined. The 9757 stamps and 294 tube-mills crushed 26,369,946 tons of ore yielding $6.28 per ton. Total costs were $4.10 per ton. Dividends paid by gold companies totaled £8,073,436. Coal output was 5,157,268 tons valued at £1,150,746; diamonds, 1,142,683 carats at $4.90 per carat; silver, 890,562 oz.; copper ore, 15,257 tons worth £330,381; and tin ore, 3387 tons worth £310,222. During the fiscal year ended March 31, 1914, all mines paid taxes totaling £2,550,147. The report contains an amazing collection of statistics of great interest.

Combustion and Smokeless Furnaces. By Jos. W. Hays. Second edition, revised. P. 118. Ill., index. Jos. W. Hays, Rogers Park, Chicago, 1915. For sale by the Mining and Scientific Press. Price, $2.

Engineers and metallurgists are fully aware of the necessity of good combustion of fuels and prevention of fume from furnace stacks. Considerable litigation has resulted from the latter trouble. Recent investigations into the soot nuisance at Pittsburgh are fresh in the minds of engineers. Enormous damage, aggregating millions of dollars annually, is caused by smoke from chimneys in cities. The burning of fuels under boilers is generally inefficient, hence smoke troubles. Hundreds of devices have been patented to try and improve combustion and reduce smoke, but few of them are worth testing. Proper design of boiler burnaces is not always considered, although of great importance. In the work under review the author starts at the bottom with a definition of heat and combustion, which is understood by few men actually operating a furnace. Combustion and the boiler-furnace is next considered, including details of fuels, heat, and losses. Air and temperature are both necessary to the complete combustion of the gases arising from soft coal. If either is lacking, there will be smoke. The author considers that the 'chimney evil' must be considered from the standpoint of health and damage to property. Chicago uses over $30,000,000 of coal per year, and the general waste due to incomplete combustion is very large. Smokeless furnaces are classified under two main heads, (1) mechanically-fired furnaces, and (2) hand-fired furnaces, with several modifications, which are all well discussed. In concluding, the author states that perfect combustion cannot be attained, but good results can be obtained. The evaporation test as an evidence of furnace efficiency, he discredits, this not applying to evidence of boiler efficiency. An appendix to the volume describes a gas analyser, draft gauge, and other instruments designed by the author.

Catalogue of Technical Periodicals. Compiled by Alice Jane Gates, assistant librarian of the Engineering Societies, with co-operation of a committee of the New York Library Club. P. 110, 8 by 10 in., cloth. Library Board of the United Engineering Societies, New York, Price, $3.

This volume, number one of the bibliographical contributions of the library of the Engineering Societies, is a worthy beginning of a promising series. It is a valuable catalogue, or rather a directory, of the technical periodicals and engineering society transactions in or near the city of New York. It is as valuable to an individual as it is to libraries, in that an engineer, by referring to it, may readily locate a periodical reference in his research notes. The seven large and representative libraries contained in the catalogue are as follows: Columbia University, Chemists' Club, American Society of Civil Engineers, Engineering Societies, New York Public, Plainfield Public, and Stevens Institute of Technology. The catalogue is a great step in a nation-wide plan to effectively record the periodicals throughout the various cities, and is the outgrowth of a suggestion made by the late Dr. John Shaw Billings to W. P. Cutter, the librarian. The attempt was made to have a complete record of foreign and domestic periodicals, that is, to include all changes of title, consolidations, record of indexes published, and suspension or cessation of publication. In short, it aims to be a concise history of every important technical periodical in the seven libraries above mentioned. The entries in the pages are compiled in an original and pleasing manner. The names of the periodicals, arranged alphabetically, are followed by a complete statement of the numbers published. Below this are given the numbers of the periodical to be found in one or more of the libraries represented. The size of the page is 8 by 10 in. and the printing is set up in two columns making it easy to follow. There are, in all, over 2600 main entries and cross-references with a list of indexes consulted, a list of the libraries and information regarding them, and a brief statement of the system followed. Finally, it is printed on heavy glare-proof paper, is strongly bound, and will prove a valuable addition to any engineer's library.

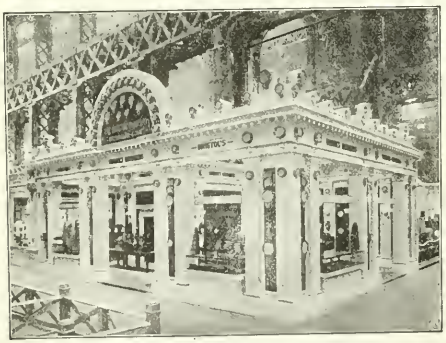
New Machines and Devices

Information based on letters and catalogues from manufacturers.

Recording Instruments at the Exposition

The Bristol Company of Waterbury, Connecticut, manufacturers of Bristol's recording instruments, indicating instruments, metal-belt fasteners, and safety set and cap-screws, has an area of 32 by 42 ft. in the Palace of Machinery at the corner of Avenue D and 2nd street.

There are two wide doorways, one on each street, and the doorway on 2nd street is surmounted by a large arch. This arch is decorated by 48 recorders, 24 on each side. There are over 150 additional recorders which decorate the ornamental cornices and the interior of the booth. These recorders are made to fit in the general style of ornamentation of the booth, and they not only serve as an architectural embellishment, but also typify the products of manufacture of the company, since they are of various sizes, shapes, and forms, from the large original 12-in. chart-recorder to the small round 6-in. chart-recorder. All of these are the same as the actual instruments, as to external appearance, the clocks and internal mechanism only having been omitted. There are over 125 recording instruments exhibited, comprising the complete line of instruments for pressure and vacuum, liquid levels, differential pressures, temperature, electricity, time, motion, speed, humidity, flow, barometric pressure, and miscellaneous measuring instruments.



EXTERIOR VIEW OF BRISTOL EXHIBIT BOOTH.

There are also shown four different styles of metal-belt fasteners, comprising the patent steel belt-lacing, patent belt-plates and split rivets, wire lacing, and oval-pointed belt-hooks.

Bristol's patent safety set and cap-screws are shown in 14 complete sizes.

The complete exhibit is carefully placarded, indicating the particular applications of the various recorders. A large part of the exhibit is well arranged on tables, so that actual demonstration and tests might be easily and readily made by any visitor. Two of these demonstrating outfits show the operating principle for the transmission and recording of temperatures and pressures up to 30 or 40 miles. There are over two dozen recorders operating continuously, showing air temperatures, voltage, frequency, barometric pressure, water pressure, gas pressure, liquid level, speed, humidity, etc. There is also an instrument indicating and recording the tide variations in San Francisco bay, operated on the electric long-distance principle.

The Bristol Company has been awarded the Grand Prize, which is the highest possible attainable, by the International Jury of Awards.

Commercial Paragraphs

The Pacific Foundry Co., of San Francisco, reports that it has secured an order for six new Herreshoff furnaces, temperature control, to be erected at the Tacoma smelter in connection with the extensions to treat additional copper ore. This order was received after having supplied four furnaces to the Garfield smelter, Utah, where they did good work.

On August 14 the Dodge Manufacturing Co., of Mishawaka, Indiana, held its ninth annual outing at Michigan City in that State. Over 3000 people, including officials of the company, employees, and friends, attended. This affair was in keeping with the company's welfare work. The company claims that it is the largest producer of power-transmission machinery in the world.

The Busch-Sulzer Bros.-Diesel Engine Co., of St. Louis, Missouri, has issued Form No. 2004, describing the Appleton, Wisconsin, water-works. The plant consists of a filtration installation and pumps. Power is suplied by two 225-hp. 3-cylinder, 4-stroke cycle Diesel oil engines made by this firm. They have been operating with excellent results for over a year, driving four 2,000,000-gal. per day double-acting triplex pumps, one at each end of each engine shaft, also two 15-kw. link-belt driven generators. Costs were reduced over 50%, on a basis of 1000 gallons pumped.

Bulltin 72 (23 pages) of the Sullivan Machinery Co., Chicago, describes the Sullivan drill-sharpener, which was illustrated and briefly covered in the Press of May 29. The machine is worked by compressed air, and is used for forging and sharpening rock-drill and hammer-drill bits and forming shanks, by hammering. The net weight is 4000 lb. Advantages claimed are as follows: quality of steel preserved, gradual work, high capacity (a new bit from bar-stock, one heat, in one minute or less), temperature, compactness, convenience, strength, variety of work, safety for operator, automatic lubrication, high-class material and workmanship, air economy, and absence of cross-strains in the machine.

The Braun laboratory appliances, consisting of crushers, pulverizers, samplers, furnaces, burners, and other equipment which is used in all parts of the mining and industrial world, have been awarded a gold medal at the Panama-Pacific Exposition. The exhibit was in conjunction with the U. S. Bureau of Mines which has maintained a working laboratory for research work that has proved extremely valuable and interesting to visitors to the Exposition. In addition to this prize The Braun Corporation of Los Angeles, and the Braun-Knecht-Heimann Co. of San Francisco, have been awarded silver medals as collaborators. The above awards are not the first ones received by the Braun appliances, gold medals having been awarded at the Expositions at St. Louis, Jamestown, Portland, and Bendigo, Australia. Braun labor-saving devices are used in the remotest parts of the world, their merits being well known.

EDITORIAL

T. A. RICKARD - Editor

POPULATION of the United States, it is estimated, has recently passed the hundred-million mark. Since 1879 the increase has been 52,494,000 or over 100% in 36 years.

ON August 14 the first year of commercial operations at the Panama Canal was completed. During the 12 months 6,494,673 tons passed through, paying toll to the amount of $5,216,149. Receipts are increasing steadily.

GALVANIZERS are buying spelter again. For their sake and that of important allied industries, we hope that the spelter market will behave itself, remaining steadily at a good, but not prohibitive, quotation, such as 10 cents per pound.

NECESSITY is the mother of invention. The exigencies of the time are stimulating the finding of substitutes for numerous substances heretofore made in regions now inaccessible to ordinary trade. Many monopolies will be shattered by the War.

PLATINUM is being exported from Colombia at an accelerating rate. In 1907 the total production was only 245 ounces; for 1914 the export returns show 9382 ounces. Most of this metal came from the Condoto river district, where the Consolidated Gold Fields of South Africa is operating.

DENVER is to figure in the munition business, it is announced. The General Ordnance Company has been organized by six manufacturing concerns, which have already secured several contracts with European governments. Colorado is making a handsome output of zinc and other metals required for making munitions.

THIS YEAR the strain felt in the autumn by reason of the financing of our harvest will not be undergone, because gold is plentiful. Crops are splendid, in quantity and in condition. Export of food-stuffs is unprecedented. The manufacture and sale of munitions is making a generous market for the base metals. No reason exists for anticipating any check in the industrial uplift.

WEALTH is being transferred from Europe to America in prodigious chunks. Mr. Charles M. Schwab, of the Bethlehem Steel Company, is reported to be in a fair way of making $75,000,000 in one year. That sum of money will be paid by European governments, and eventually by European people, to an individual in the United States. Other sums of money running into colossal figures will suffer similar migration across the Atlantic.

COPPER is said to be produced at the Kennecott mine, owning the Bonanza deposits on the Copper river, Alaska, for 5 cents per pound. The record of the previous decade was the 7 cent cost of the Wolverine in Michigan, but there the figure has risen to 8½ cents. The big disseminated copper deposits lowered the record, notably the Utah Copper; later the Chuquicamata (of the Chile Copper Company) took the palm for cheapness, at under 6 cents per pound.

ON consulting our staff, we find that the things most worth seeing at the Exposition are (1) exterior of the Fine Arts building, (2) model of Panama Canal, (3) the Model Mine, (4) the exhibit of the U. S. Geological Survey and of the Bureau of Mines, (5) the Canadian exhibit, (6) United States Steel Corporation's exhibit, (7) the French building, (8) school systems in Educational building, (9) assembling of the Ford automobile, (10) the Bay of San Francisco.

CO-OPERATIVE experiments in production in the United States have failed and are doomed to fail because they do not give free scope for individual ambition. The few misplaced drones who do the loafing and share equally in the profits drag down the better men to their own level. Another reason for the failure lies in the remoteness of the reward. A profit that may come in six months or a year has not enough attraction to overcome the desire of taking life easily in the present. A more formidable obstacle to co-operation arises when losses ensue; for while workmen are always willing to divide profits, they are usually opposed to any sharing of loss.

FOR the first time in the history of the country the the mining brokers of the United States are to meet in conclave to formulate a few simple rules for the protection of the mining industry and the investing public —so it is announced. And it is added that "by realizing these two purposes" the brokers expect to further their own interest. The idea is excellent. Stock-exchanges all over the country have arranged to send delegations to this brokers convention, which is to be in session in this city from September 21 to 25. The circular says that this meeting will be concurrent with that of "the American Mining Engineers," but the meeting of the Institute will be held during the week previous. However, the

Mining Congress will be in session at the dates mentioned. It would be well if a committee of brokers would appear before the Congress and explain its ideas for "eradicating those pests and hangers-on of legitimate mining enterprises which have in the past done much to discredit the mining industry" and for "eliminating the irresponsible and market-rigging elements in the brokerage business." A frank discussion might be useful; certainly it would be interesting.

THE mineral wealth of a country may be compared to a sum of money hidden in the ground. it does not renew itself and every dollar extracted leaves just so much less for future use. Yet it is a singular fact that among a people supposedly grounded in the rudiments of political economy, the progressive exhaustion of this precious resource is everywhere heralded as a triumph of enterprise and a gauge of national prosperity. The nation publishes periodically the record of the scattering of its assets never to be regained and waits with a smile of complacence for general congratulation. The moral, therefore, is to avoid waste in the exploitation of our mineral resources.

RECENTLY a San Francisco evening paper, which it would be unkind to name, published a financial article announcing that "California's predicted gold mining boom seems near." This prediction is based on the fact that a certain Mr. Leopold Hyde, a South African mining engineer. not known to us, had reported that "in mineral wealth California is a land of Aladdin. She leads the earth in the production of gold, quicksilver, and oil, and vast areas of unexplored mineral territory within her borders await the advent of the prospector and miner." Whereupon the financial expert of the *Evening Yawp* makes the observation: "It was with such a report before them that British capitalists, after the advent of the War, began to investigate the California goldfield." That seems unlikely. London capitalists are not quite educated to the appreciation of such rhetorical confectionery. Besides they have heard of California before. Moreover the production of gold in the Transvaal was $172,602,160 last year and that of California was $20,653,496, so that the aforesaid capitalists may find reason to doubt the other statements of the supposed South African mining engineer, who appears not to have heard of the Transvaal as a productive goldfield. In truth, the day has gone for such flapdoodle. It may be good enough for the financial columns of the *Evening Yawp*, but it does not further the welfare of the mining industry. California does not need such twaddle to win recognition in London or elsewhere.

Silver

While gold has appreciated and the base metals have exhibited extraordinary fluctuations in price, the quotation for silver has been steadily downward, until the low record of 46⅝ cents per ounce was reached on August 31. However, we do not doubt that the end of the War will synchronize with an improved market for silver, because that precious metal will be required in large quantity for subsidiary coinage. In Europe, as in Mexico, paper has displaced silver as a medium of common exchange. That condition will be reversed, to a large extent, when normal industry revives in the regions now subject to lawlessness, for to the peaceful dweller in Poland the Germans and the Russians are destroying industry even more effectually than the Carranzistas and the Zapatistas in Durango. Meanwhile our readers will find a good deal of timely information on the silver market on our metal page from week to week. There we give data concerning the London, Indian, and Chinese markets for silver. To realize the part that India plays it is only necessary to say that India absorbs 55% of the world's annual output of silver and produces only 2%, mostly as a by-product in the gold mining of the Kolar district. India's capacity for absorbing the precious metals is a fascinating subject. Estimates of the value of these hoardings runs into billions of dollars. The cause for it is similar to that at work now as between New York and London, namely, the balance of trade, which, for a long time, has been greatly in favor of India. The simple habits of the people, the character of the climate and the soil unite in reducing the necessities of life to a minimum; so that foreign purchases are small as against their exports. In eastern Bengal, for example, the annual sale of jute alone represents $2.50 per head of the population. This goes out mainly in exchange for gold and silver. Meanwhile the Mexican production during the last three years has not decreased as much as might be supposed; we have no reliable figures, but we hazard the guess that, until recently, Mexico has been contributing a large proportion of its normal production of 70 millions, out of the 225 million ounces produced by the whole world. The two factors that are depressing silver are the lessened purchases in the Orient and the increased production of the metal as a by-product in copper mining.

Physics and Psychology

On another page we publish an elementary account of the scientific principles underlying the process of concentration by froth-flotation. This is written by one who knows little about the subject, but, like many of his readers, is anxious to learn. One way to learn is to ascertain what you don't know. In the case of the new metallurgical process the world of knowledge outside human ken is immense. Our own point of view is sympathetic to that of our readers, to most of whom also the subject is wrapped in obscurity. In the land of the blind, the one-eyed is king. Indeed, our own study of flotation leads us to conclude that those who have had two good eyes for the purpose of technical observation have made their vision violently astigmatic by prejudice. The subject is frothy with the vindictiveness generated from private quarrels and patent litigation. For that

reason most of the published information has to be read with frequent pinches of sodium chloride. Such as they are, the printed writings on flotation concern themselves mainly with the manipulation and apparatus of the subject; usually they ignore the physics involved. When references are made to basic principles, it is in a casual, and misleading, way. For instance, we have found a mention of the effect of oil on surface tension in four articles, and in each case the statement is made that the oil increases the surface tension. It does not. Any book on physics will furnish that elementary information. On the other hand, those patentees that have studied the science of the subject with real insight have written little or nothing on it. Obviously they fear to compromise themselves. The multitudinous articles on the Elmore process, emanating from the friends of the patentees, are devoid of scientific information. So the later articles on the process developed by Elmore's opponents likewise tell next to nothing about the underlying realities. The most recent information is to be found in the trial records, giving the testimony of the experts in the lawsuits, but even these are only distantly related to scientific evidence, for the experts are advocates, not witnesses; they come into court with a bias that renders all they say subject to heavy discount. However, from these and other sources we have gleaned some bits of knowledge that may prove useful to our readers. The flotation pundits will find much that to them seems wrong in our efforts to make a logical presentation of the physical phenomena, or appearances, behind the process. They will be welcome to their feeling of superiority. Not one of them can describe flotation in terms that three others will accept as accurate. Moreover, the recognition of one or two unobtrusive facts might embarrass them when next they take the stand, so we shall excuse them from reading our amateur analysis. It is 'amateur' in the real sense of the word, for it has been a labor of love to make this diagnosis of the effects that unite in giving the miner another means of extending his profitable exploitation. Flotation is a process of extraordinary technical interest. We hope that our article will be a stimulant to investigation and to observation. It may lead others to contribute their views, not the Montagus and the Capulets of the flotation vendetta, but the Mercutios that cry "a plague on both your houses." We refuse to keep silent, or to ask others to keep silent, on the science of a metallurgical process just because it is the victim of litigation. The litigation has been proceeding in various courts for ten years and we have no assurance that it will not last for ten years more. We do not see how the elucidation of the subject can hurt a rightful patent and we do see most clearly how the mining industry is suffering, and will suffer, from the placing of an embargo on technical knowledge. The days of secret processes are gone: they are either patentable and protected by patent, or they are not. The one thing that is clear is that the granting of patents under existing regulations makes only for confusion. A patent should not be given until it has been thoroughly investigated by competent men, and once given it should be protected and regulated by the whole power of the State.

Meanwhile we must take things as they are, recognizing two existing conditions: (1) the hindrances offered to the publication of such knowledge as is available and (2) the incompleteness of that knowledge even when available. Cohesion, surface tension, and viscosity are real but subtle forces, requiring refinements of research such as are rarely provided in a metallurgical laboratory. To be frank, the theory of flotation has not been developed by metallurgists to the point where it is accepted by physicists. To understand it will require painstaking investigation of the nature of liquids—an elusive problem. Even if we could allot to surface tension and to viscosity their respective parts, we should still be in the dark over the preference of the bubbles, as of the oil, for the metallic particles. We have yet to learn what part electro-statics plays. However, if we do not know 'why,' we do know 'how,' for flotation is a fact, no matter how mysterious the physical laws that lurk in the background. In succeeding issues we shall give an account of the history of the process, the present state of the art, and its application to various ores.

The Engineering Congress

Next week San Francisco is to be the place of meeting for the International Engineering Congress of 1915. The movement resulting in this convention began to take definite shape at a meeting of the representatives of the American Societies of Civil and Mechanical Engineers On October 24, 1911, in this city. Those present were Messrs. A. L. Adams, C. Derleth, Jr., G. W. Dickie, C. E. Grunsky, E. C. Jones, and T. W. Ransom. At that meeting it was decided to issue invitations to all the engineering and technical organizations having local sections in San Francisco to send representatives to a meeting on November 2, 1911, to discuss ways and means for accomplishing the purpose designated. At this second meeting eight societies were represented, as follows:

American Society of Civil Engineers,
C. Derleth, Jr., and C. E. Grunsky.

American Society of Mechanical Engineers,
G. W. Dickie and T. W. Ransom.

Pacific Coast Gas Association,
E. C. Jones.

American Institute of Electrical Engineers,
H. A. Lardner.

Mining and Metallurgical Society of America,
F. W. Bradley and S. B. Christy.

American Institute of Mining Engineers,
W. C. Ralston and E. T. Blake.

American Chemical Society,
F. T. Green and B. S. Drake.

Technical Society of the Pacific Coast,
Marsden Manson and Otto von Geldern.

On this occasion a resolution was adopted that each

society should send three delegates to a conference on January 15, 1912, for the purpose of formulating plans for holding the Congress in conjunction with the Panama-Pacific Exposition in San Francisco during the year 1915. At that conference the various societies were represented by the following delegates:

American Society of Civil Engineers,
A. D. Foote, C. D. Marx, and W. A. Cattell.

American Society of Mechanical Engineers,
Calvin W. Rice, W. F. Durand, and E. C. Jones.

Pacific Coast Gas Association,
John A. Britton, C. O. G. Miller, and Frank A. Leach, Jr.

American Society for Testing Materials,
C. B. Wing, Loren E. Hunt, and C. F. Wieland.

Society of Naval Architects and Marine Engineers,
W. F. Durand, F. W. Hibbs, and G. W. Dickie.

Mining and Metallurgical Society of America,
F. W. Bradley, C. W. Merrill, and E. A. Benjamin.

American Institute of Mining Engineers,
W. C. Ralston, Edwin Blake, and S. B. Christy.

American Society of Electrical Engineers,
H. A. Lardner, S. J. Lisberger, and G. R. Murphy.

Technical Society of the Pacific Coast,
Otto von Geldern, Marsden Manson, and Col. W. H. Heuer.

Thereupon it was finally decided that a Congress be convened under the auspices of five national engineering societies, namely:

American Society of Civil Engineers.

American Institute of Mining Engineers.

American Society of Mechanical Engineers.

American Institute of Electrical Engineers.

Society of Naval Architects and Marine Engineers.

It was arranged also that the Congress should be managed by a committee consisting of the presidents and secretaries of the five societies and four other members of each society to be duly appointed. This was approved by each of the societies. On March 6, 1913, the local members of the Committee of Management met in the board-room of the Mechanics Institute for the purpose of perfecting the organization. On that occasion Professor Durand was elected chairman, Mr. W. A. Cattell, secretary, and a committee was appointed consisting, in addition to the two mentioned, of Messrs. E. H. Benjamin, W. G. Dodd, A. M. Hunt, and T. W. Ransom, to formulate a plan of organization and nominate permanent officers.

In order to secure national support, it became necessary for the engineers of the Pacific Coast to show their faith in the project by subscribing to the guarantee fund of $10,000. This was done, so that when the official representatives of the Five Societies assembled on March 6, 1913, the $10,000 had been fully subscribed.

On March 14 the plan of organization, together with the constitution and by-laws for the government of the Committee, was adopted, the temporary appointments of chairman and secretary being made permanent. Thereafter the work of preparing for the Congress was started in earnest, Mr. E. J. Dupuy being retained as executive secretary. The fund guaranteeing the expenses of the Congress was underwritten as follows:

Engineers of the Pacific Coast	$10,000
American Society of Civil Engineers	9,000
American Institute of Mining Engineers	5,000
American Society of Mechanical Engineers	5,000
American Institute of Electrical Engineers	5,000
Society of Naval Architects and Marine Engineers	2,000

The amounts underwritten by the various societies were proportional to their respective memberships.

Delegates to the Congress have been appointed by 29 societies and 5 Government departments:

United States	10	Hungary	1
Great Britain	9	Spain	1
France	2	South Africa	1
Canada	1	Argentine	1
Sweden	1	Netherlands	1
Switzerland	1		

Papers have been received in large number: from the United States, 158; France, 6; England, 14; India, 3; Italy, 9; Netherlands, 5; Canada, 5; Spain, 2; Sweden, 2; Russia, 2; South Africa, 1; Australia, 2; Japan, 4; China, 2; Switzerland, 2; Austria, 1; Argentine, 2; and Chile, 1.

Subscriptions to membership number 3082, of which 816 are in foreign countries. The five societies contributed from their membership as follows:

American Society of Civil Engineers	811	or 10.5%
American Society of Mechanical Engineers	458	7.5
American Institute of Electrical Engineers	403	5.3
American Institute of Mining Engineers	360	7.2
Society of Naval Architects and Marine Engineers	69	8.3

Advance copies of the papers to be presented at the Congress indicate that a wide field of knowledge will be fittingly covered. A large mass of useful information will be compiled. Even more important will be the opportunity given the exponents of the various branches of engineering to make acquaintance and compare notes. Representation at the Congress will not be international to the extent desired, for the organized calamity in Europe will have prevented many of the representatives of trans-Atlantic technology from coming hither at this time. South America and Canada will be well represented, so that the attendance of the Engineering Congress will be largely American, although many papers have been contributed by foreign engineers. Well, America is a continent, large and diversified, on which engineering has played so glorious a part that for a day or two we can try to forget the destructive use of applied science by our friends across the sea. Nor need we feel like Nero fiddling while Rome is burning, for engineering, in the main, is constructive; when Peace prevails once more, all the resources of the profession will be organized to restore and rehabilitate the regions now devastated by War. Engineering is synonymous with material civilization. The professional idea connotes the ethical progress of humanity.

The Exposition—An Impression

By T. A. RICKARD

When Vasco Nuñez de Balboa stood lone upon a peak in Darien, four hundred years ago, and looked upon the western sea, he broke the trail for the builders of the Panama Canal. On August 5, 1775, Juan de Ayala sailed into the Bay of San Francisco, and the fabled land of California became a fact. On July 9, 1846, the American flag was raised in the plaza of the Spanish mission settlement. On February 4, 1915, the piercing of the isthmus by an American-built canal was celebrated in appropriate fashion on the shore of the Golden Gate. The dates, even to the days of the month, emphasize the human limitation of time and the immortal glory of each achievement. The past of California is as fragrant with romance as a portico entwined with jessamine in an April twilight. So is the present, to those attuned. Color is in the eye, romance in the imagination. I am standing on the shoreward steps of the Court of the Universe in this great city of palaces called the Exposition; right and left are noble colonnades extending east and west until they merge in domes and towers innumerable; in front, shoreward, is the great court peopled with statues that are eloquent in allegory; its spacious magnificence softened by a parterre of rhododendrons in lavish bloom and by the pigeons that have made their home among the cornices. The Tower of Jewels flashes in the sunlight and through the great arch underneath I can see the environs of San Francisco, a hillside white and purple with houses and foliage, a Sicilian background under a Sicilian sky. Indeed the color is that of the sunny shores of the Mediterranean.

The prevailing tint is golden sienna, for the structures are faced with travertine, like that of Rome. Not new, but old, they look; not tinselled, but mellow; worn by age, as in Italy; a composite of particles of varying color, giving a richness that the sunlight bathes in glory. The scheme of coloring is superb. The domes are variously terra cotta, pale green, and orange. Behind the colonnades I see glimpses of a pink background, while the vaulted ceilings are deep blue in contrast with the yellow in the travertine of the walls and columns. Nothing has been half-done. The detail of adornment is so lavish as almost to be florid. The statuary is original, audacious, and symbolic. Urns and vases in verde antique are distributed among trees, shrubbery, and flowers. These give a setting that escapes artificiality. Nowhere except in such a climate and under such a sky could the general architectural effect be possible. It is the glory of the antique world on the Aegean shore.

When you are tired of wandering down the long aisles of the buildings and the broad avenues outside them, go to the Marina or water-front and give the tired senses an opportunity to rest on the panorama of land and water. This is an exposition in itself, but one that will not fade. The quiet Bay narrows to the Golden Gate, that portal of undying romance. The white house on the island of Alcatraz looks like a palace on Mitylene. The blue hills of Angel island and the verdant cliffs of Sausalito on the opposite shore frame the sunlit waters. Above the nearer hills rises the dark peak of Tamalpais. In the foreground is a battleship. It is the *Oregon*, quietly at anchor, as if to remind us of the part she played in the sequence of events that has been crowned with this Exposition. Indeed she is the *raison d'etre*. When war with Spain was impending in the spring of 1898 she left San Francisco, under the command of Capt. Charles E. Clark. When she reached the southern end of the double American continent, the United States had declared war. We wondered whether she would be intercepted by the enemy's cruisers or whether she could arrive in time to join the American fleet in a naval battle off Cuba. The *Oregon* left San Francisco on March 19, reached Puntas Arenas on April 21, Rio Janeiro April 30, and Key West on May 26, doing 14,000 miles in 68 days, just in time to take her part in the battle off Santiago. It was an object lesson to the Navy Department and to the Nation. If the fleet was to be available for prompt defence on either coast, it was essential to lessen this 14,000 miles by a short cut through the isthmus linking the two American continents. It has been done, and the *Oregon* is moored out yonder in the Bay as if to remind us of the accomplished fact.

At night the lighting of the Exposition is effected with all the startling beauty that electricity has placed in the hands of man. To many visitors the loveliest memory of their sojourn here will be the Fine Arts Palace as seen in the early evening when the twilight joins with artificial lighting in weaving a spell that conquers time and place. A lagoon, fringed with cypress and other evergreens, makes a foreground for the double colonnades that stand like a temple not made with hands. They are dimly lighted. We walk toward a noble perspective, getting unexpected glimpses of columns and statues, water, and flowers. The beauty of line and color is repeated on the still face of the lagoon, where, on an island, a kneeling goddess feeds the sacrificial flame. The searchlight throws its penciled ray athwart the scene. Suddenly, aloft, on the top of a giant column, in mid-air, I see the mighty forearm and shoulder of the Adventurous Archer, who, with feet firmly planted, is sending an arrow into the unknown. The sudden illumination of this heroic and eloquent figure is bizarre but impressive. There he stands as the

symbol of the pioneering spirit, shooting across the water, into the unknown, at a venture, while Hope kneeling at his side seconds his strength with sympathy.

The picture is ephemeral! A year hence it will be gone. The Exposition covers 600 acres and on it has been spent $50,000,000 in the erection of buildings and the assembling of exhibits. Not many months ago the site consisted of sand-dunes and marshes, varied by the shanties of a neglected foreshore. A small part of the Exposition is built on the Presidio, the military reservation dating from historic days. Early next year all these lordly palaces of art and industry will be 'wrecked' systematically, every broken part of them will be removed, so that the streets and alleys of an unlovely suburb may be restored. The dream will become a memory.

It is indeed the fabric of a dream, the dream that came true. And like a vision at the dawn of day it must fade. That pathetic thought is ever present. From sand-dunes and marshes it sprang; into them it will disappear.

But while the physical part of this Exposition is ephemeral, the spirit of it will not pass immediately. Among the millions that come and go, whether staring half-intelligently or observing with real insight, there will be many to whom the splendor of the scene and the beauty of the vision will be an abiding memory. On them the allegory of the statuary will not be lost, on them the message of the artist will not be wasted. And the fact that most of them came from the outworks of an intensely industrial civilization will make the psychical effect all the greater. It is well for men to learn that they do not live on bread alone; it is well for them to endeavor to industrialize their lives without also commercializing their souls.

Production of Gold and Silver

The Bureau of the Mint and the Geological Survey completed their joint calculation of the production of gold and silver in the United States for the calendar year 1914, and the figures are given below:

The decrease in gold production was mainly in two states—Nevada, $441,200, and Utah, $193,300—while the increases were as follows: Colorado, $1,792,700; Alaska, $1,345,900; California, $1,010,600; Montana, $822,700.

The largest gain in silver was in Idaho—3,096,700 oz.

	Gold.		Silver.	
State or Territory.	Fine oz.	Value.	Fine oz.	Value.
Alabama	595	$ 12,300	300	$ 200
Alaska	800,471	16,547,200	865,900	478,800
Arizona	221,020	4,568,900	4,439,500	2,455,000

The production of gold was greater by $5,647,400 than in 1913, and the production of silver was $5,653,600 fine ounces greater.

California gained 599,300 oz.; Arizona, 527,500 oz.; Alaska, 499,200 oz.; and Utah, 439,700 ounces. California was first in gold, and Nevada in silver production.

What Is Flotation?

By T. A. RICKARD

Flotation, in its latest phase, is a process of concentrating ores by frothing. When crushed ore, previously mixed with water and a relatively minute addition of oil, is agitated violently in the presence of air, a froth is formed. This froth, rising to the surface of the liquid mixture, is laden with sulphides or other metallic particles, while the earthy material, or gangue, subsides to the bottom. This froth is "thick, coherent, and persistent."

The formation of this froth depends upon a number of physical causes, of which the buoyancy of oil is the one most generally associated with the flotation process. Surface tension, however, is the phenomenon to be considered first. Then viscosity.

Every millman has had occasion to notice how sulphides are carried on the surface of wash-water in a

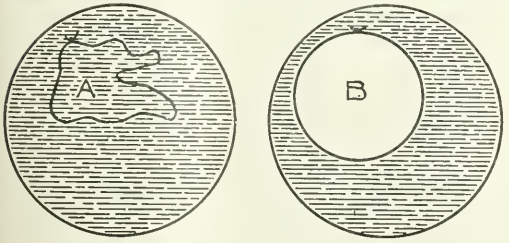

Fig. 1.

stamp-mill: for example, when water is passed over the dry surface of an amalgamating-table or a vanner-belt. The metallic particles are dry and to their surfaces is attached a film of air that buoys them on the water. To a similar cause is due the loss of 'float gold' in tailing. Most of us learned early that grease of any kind was bad for amalgamation. It 'sickens' the quicksilver, coating the globules so that they do not coalesce but remain in a 'floured' or minutely globular condition. This may account for the loss of quicksilver, but the further loss of gold must be imputed to the fact that the fine scaly bright gold attaches itself readily to the oiled spheres of mercury and is carried with them into the creek.

The surface of any liquid behaves as if it had a film or elastic skin. To this fact is due the variation in the maximum size of drops of different liquids. As the drop enlarges, the strength of this skin is exceeded; then the drop breaks and the liquid falls. When an iron ring is dipped into a solution of soap, it will be seen, on taking it out, that a film of the liquid stretches across the ring. If a small loop of cotton, previously moistened with the solution, is placed on the film left on the ring, this loop can be made to assume, and retain, any form, such as is shown at *A* in Fig. 1. If, however, the film within the loop is broken, the loop immediately assumes the circular form, shown at *B*; and if it is now deformed in any way, on being released it springs back at once to a circle.

These phenomena indicate that the particles at the surface of a liquid have a greater coherence than the particles in the interior of the liquid. The force that does this is surface tension. The experiment with the ring and the loop, for example, is explained by the fact that, in the first place, "the surface tension of the liquid acts equally on both sides of the cotton, but when the film inside the loop is broken, the surface tension only acts on one side, and hence draws the loop out into a circle."*

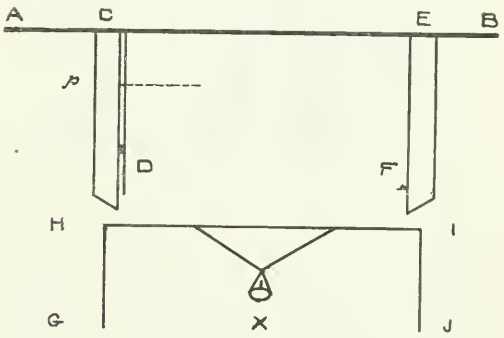

Fig. 2.

Surface tension can be measured. A framework[1] (Fig. 2) consisting of a transverse bar *A B*, and two grooved slips *C D* and *E F*, will allow the piece of wire *G H I J* to slip freely up and down. The wire *H I* is pushed against *A B* and a quantity of the liquid is applied between them. The little pan *X* is loaded with sand until the wire *H I* is pulled from *A B*. The minimum force required to do this is *mg*, the weight of *m* grams. This weight suspended on the film equals the tension of the film on the wire. If the film stretches until the wire *H I* is at *p*, then the film has an area *C E.Cp*. The total weight *mg* is distributed over the breadth *C E*; whence, if *T* represents the superficial tension across the unit of length *C E*, then $mg = T.C\,E$ or $T = \frac{mg}{C\,E}$.

Thus the force of surface tension between water and air has been determined; it is 3¼ grams per linear inch or 81 dynes per centimetre, which being interpreted means that 40 grains would be supported by a film one foot long.

*'A Text-Book of Physics,' by W. Watson, page 191.

[1]'A Text Book of the Principles of Physics,' by Alfred Danniell, 1911.

The surface tension of various liquids is as follows:

Liquid.	Sp. Gr.	Tension of surface separating the liquid from Air.	Water.
Water	1.00	81	....
Mercury	13.54	540	418
Alcohol	0.79	25.5	....
Olive oil	0.91	36.9	20.56
Turpentine	0.88	29.7	11.55
Petroleum	0.79	31.7	27.8

These are given in dynes per centimetre as determined by Quincke, and recorded in the Encyclopedia Britannica. However, a liquid has another characteristic that must not be overlooked, namely, viscosity or resistance to flow. This gives toughness to the superficial film. Water-spiders will run over the surface of a pool like boys on skates over thin ice. The spider's feet do not break through, although each tread makes a dimple on the surface. H. H. Dixon actually measured the pressure exerted by the spider's feet on the water. He photographed the shadow of the dimple and then mounted one of the spider's feet on a delicate balance and made it press on the water until it made a dimple of the same depth as that previously observed.

The next phase of the subject is illustrated by the familiar experiment with a greased needle. If you place an ordinary needle, say, a lace needle suitable for use with No. 80 thread, on the surface of a bowl of water, it sinks at once to the bottom, in obedience to the law of gravity. If, however, you pass the needle through your hair,[2] so that it becomes greased, it will float on the water. Why the difference of behavior? In its ordinary state the needle has a film of air attached to it. That film, being loosely held, is readily displaced by the water, so that the needle becomes wetted, that is, its weight causes it to break through the elastic skin constituting the surface of the water. On the other hand, when the needle is greased, the film of air around it is displaced by a film of oil, which is firmly held, because lustrous metallic surfaces have a selective adhesion for oil. Moreover, gases have a marked adhesiveness for oils, so that air adheres readily to the film of oil on the needle. On account of this envelope of oil and air, the needle is not wetted, that is, it fails to rupture the surface. The needle lies in a depression in the surface of the water, but the amount of displacement does not account for the floating. Viscosity, however, may play a part, by increasing the tenacity of the film, the particles of which are so held together, or cohere, that the needle fails to part them. In short, although it is eight times heavier than water, the steel floats.

Another suggestive experiment is that of the grapes in soda-water. Fill a glass two-thirds full with soda-water from an ordinary 'syphon' and then drop two or three small grapes into it. The grapes sink to the bottom, but they become restless almost immediately and soon rise to the surface, one after the other. They do not remain there; first one and then the other sinks. This performance will continue for half an hour, the individual grapes rising and falling, not always the whole way, but maintaining a condition of intermittent activity. They become quiet only when bubbles cease to be generated at the bottom, that is, when the carbonic acid gas has been driven out of the water by the relief of pressure. By watching, it is seen that the bubbles attach themselves to the grapes and buoy them to the surface, where the bubbles break. Sometimes a couple of grapes will collide and cause the adhering bubbles to become detached, so that one or both of the grapes sink. In the end the bubbles become too few to buoy the grapes, so that the latter rise only part of the way; finally, they lie motionless at the bottom. During the early and active part of the performance, the grape will strike the surface of the water and rebound from it as if it were a membrane.

The buoyancy of oil is the physical fact most associated with the first development of flotation, although it is subordinated in the later phases of the process. Oil has a specific gravity less than that of water, and therefore rises to the surface when mixed with water. The lighter oils range in specific gravity from 0.8 to 0.95, as against the 1.0 of water, so that the margin for buoying particles heavier than water is small. For instance, to make a mixture of zinc sulphide and oil as light as water, it would be necessary, even with the lighter oils, to use from 3 to 15 times as much oil by weight as the blende. This suggests that flotation, even as conducted on the lines of the older patented processes, cannot be due entirely to the buoyancy of oil.

The selective adhesion of oil for particles having a metallic lustre is a decisive factor in the process. It has been said that this adhesiveness is characteristic of sulphides; but it is exhibited by tellurides and by graphite also. Similarly, it has been imputed to 'mineral' and to 'metallic'[3] particles, but both terms would include substances outside the range of this phenomenon. Apparently it is the metallic lustre that is the decisive factor, for this would include the minerals especially amenable, such as molybdenite, graphite, the tellurides, and the bright sulphides. The effect of this marked preference of oil for lustrous metallic surfaces is intensified by the fact that gases (such as air) have a similar adhesiveness for oil, so that, if present in water, they will join in preventing the wetting of the metallic surfaces. It is an equally important fact that quartz and other gangue-minerals, having a 'non-metallic' as against a 'metallic' lustre, exhibit the opposite preference: they are feebly adhesive to films of oil, and therefore to those of gas, while they are strongly adhesive to water, that is, they are easily wetted. The reason for this difference is not known; it may belong to the, as yet, mysterious realm of electro-statics, but it is a fact that the curve of con-

[2]Or even through your fingers.

[3]'Metallic,' in this context may mean minerals with a metallic lustre, including graphite, and 'mineral' may be meant in the sense of ore, the valuable part of the vein or lode, as distinguished from the worthless earthy matter or gangue. In French, *minerai* means 'ore.' Sometimes 'sulphide' is preferred, but that excludes the tellurides and graphite. At least one sulphide without metallic lustre is readily amenable to flotation, namely, cinnabar.

tact, or wall-angle, between metallic particles and water is convex while that between earthy particles is concave.

Whatever the reason for this difference, it can be accentuated by acidulation of the water. "Acidified water has a greater wetting power than neutral water." For this fact also no satisfactory explanation is forthcoming. In some cases, the acid may be supposed to dissolve any coating of oxide on the metallic surface, rendering it more lustrous, while on the other hand, the acidity of the water may give it a corrosive penetration beneath the surface of the gangue.

The addition of acid in quantity produces another effect, namely, effervescence or the liberation of carbonic acid gas by the reaction with calcite, rhodochrosite, or other carbonates such as are often present in the ore. This generates bubbles that will buoy the metallic particles, whether oiled or not. But water contains air in solution; hence by heating the water, or by diminishing the pressure, it is possible to release the air in the form of bubbles that attach themselves to the metallic particles, like the bladders used by persons learning to swim. Moreover, by a violent agitation of the mixture of ore, water, and oil (if added) it becomes easy to entrain or entangle a large volume of air, which will rise through the mass in the form of myriad bubbles, constituting a foam or froth of varying strength and persistence.

Oil reduces the surface tension of water, that is, between water and air. Pure water has great surface tension, it also has no superficial viscosity; that is why it will not froth. The addition of oil lowers the surface tension and imparts a decided viscosity to the surface of the water. That is why the pouring of oil on troubled waters abates their turbulence. That also explains why the placing of oil in stagnant pools kills the larvae of the mosquito, which then find it impossible to adhere to the surface by their breathing-tubes. (See Fig. 3.)

Consider the beautiful soap-bubble. The oil of the soap is an impurity that lowers the surface tension of the water; by stretching of the film of the bubble this effect is diminished through the dilution of the impurity, making the film stronger and less prone to contract.[4] Thus it renders the bubble more persistent. The bubble therefore is another illustration of surface tension, for it is an elastic skin of water enclosing gas, like a balloon. Here also the property of viscosity comes into play, for the addition of oil to the water, more particularly after exposure to the air, as in agitation, gives tenacity to the superficial film. The combination of low tension and high viscosity enables a bubble of gas, rising through the liquid, to lift the surface film of the liquid, which the tension of the bubble-film is not strong enough to break, so that the bubble endures.[5] The noise made by the bursting of a bubble suggests the fact that it is a receptacle of energy.

The bubble is spherical because the sphere is the shape involving the smallest surface or superficial area. The bubble has an affinity for the lustrous metallic particles and adheres to them, as it also adheres to the smooth sides of a glass. This particle of air, or other gas, is enveloped in an elastic skin of the contaminated viscous liquid in which it has been generated and the metallic particles do not break through that skin for the same reason as the greased needle failed to be drowned in the water.

The addition of soluble oils assists the formation of bubbles in the mass of ore and water. These three constituents of the flotation pulp are mixed intimately so as to form an 'emulsion,' such as is typified by mayonnaise. The air present while the emulsion is being made furnishes the gas for the bubbles. In order that they may lift the metallic particles, they must endure during the

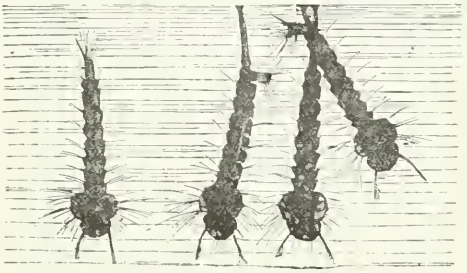

FIG. 3. LARVAE OF MOSQUITO UNDER THE MICROSCOPE.

period required for the complete separation of the metallic particles from the earthy particles, that is, the sorting of the valuable from the non-valuable components of the ore. For the purpose of metallurgical concentration the rate at which the bubbles burst must be slower than that at which they are being formed. An effective froth represents a multiplicity of persistent bubbles. The relative stability of the bubbles depends also upon the kind of oil employed. Pine-oil makes a brittle film; creosote yields an elastic envelope.

By a wonderful correlation of physical forces, the metallic particles become attached to the bubble, made in the metallurgical emulsion, in such a way as to serve as a protective armor, the particles of varying size interlocking on its spherical envelope. The bubbles without mineral are like a balloon with a weak gas-bag, which is likely to burst, while the armored bubbles are like a balloon with a strong gas-bag, which does not burst. Variety of size among the metallic particles favors the construction of the interlocking mineral coat on the bubble, just as materials of various size help to make a dense concrete. Hence slime is no hindrance.

Intimate mixing is required. The more thorough the mixing, the cleaner the separation of the metallic from the earthy particles. This is said to be due to the complete oiling of the metallic particles, but it is a fact that no oil can be discerned on the concentrate when using the $\frac{1}{3}$ to $\frac{1}{2}$ pound of oil per ton sufficient in most cases for the purpose of the process. The mixing may be beneficial for reasons other than the oiling of the con-

[4] C. V. Boys, 'Soap Bubbles,' page 105.

[5] Danniell, *Op. cit.*, page 278.

centratable parts of the ore; it may cause enough friction to clean the metallic surface; it may promote such a solution of the oil in the water as ensures the formation of the right kind of bubbles for a mineral-carrying froth. Heat, by the injection of steam, increases the miscibility, or ability to be mixed, of the oil, thinning it so that it will extend over a larger surface, as butter is warmed to make it spread over pop-corn. Many common oils, such as 'red oil' and other forms of oleic acid, are solid at the ordinary temperature, so that heat sufficient to raise the temperature of the emulsified pulp to about 80° F. is desirable.

To apply this process of concentration, the ore is crushed to the degree of fineness required to separate the metallic minerals from the earthy gangue. This may mean anything from 40 to 200-mesh. The crushed ore is then mixed with water in the ratio, say, of 3:1, although theoretically 2:1 would make a better emulsion; oil is added, say, in the proportion of ½ lb. per ton of ore; and the mixture is agitated violently in the presence of air, by paddles or beaters, by passage through a centrifugal pump, or by jets of compressed air. Acid is not necessary, as we now know,[6] although it has heretofore been considered requisite. Whether oil is absolutely essential is open to doubt. Agitation of the pulp in the presence of air is the prime factor in producing the desideratum, namely, a froth. What machines are best adapted to ensure proper agitation is a matter for separate consideration. Aeration of a liquid by agitation in the presence of air and forcing of the air into it so as to form multitudinous small bubbles, producing a froth, is done every day in the domestic operations of the beating of eggs and the whipping of cream.

We have now got our froth. This, as it accumulates on the surface of the emulsified pulp, may be from 2 or 3 inches up to 10 or 15 inches thick. It is so densely coated with the sulphides as to be black, while the gangue that falls to the bottom is so clean as to be white. By skimming, using radial arms or scrapers, or a simple flow, the froth is removed to a secondary receptacle or 'cell,' of the spitzkasten or V-shaped type, where it is cleaned by a repetition of the process, making a high-grade concentrate, while the discard goes back for retreatment. In short, all that is needed is some arrangement for thorough mixing and aeration, by the use of paddles or air under pressure; then the removal of the resulting froth so that the floated mineral will not drop when the bubbles break. When the froth has been collected, it is filtered, yielding a cake containing about 10% moisture, which may be dried before shipment or final treatment for the extraction of the precious metals.

CORRECTION. Our attention has been drawn to a slight error in the article on flotation at Anaconda. The dimensions of the Hardinge mills are reversed; they, of course, are not 10 ft. diam. by 4 ft. long, but 4 ft. diam. and 10 ft. long.

Magnetic Surveying

A magnetometer was used in surveying an area containing nickeliferous pyrrhotite where more or less complete data had already been secured by diamond-drilling. It was thus possible to compare the evidences of mineralization, as indicated by the magnetometer, with the actual conditions as previously determined. The results of this work indicate that, when the orebodies are fairly uniform in character and composition, the magnetometer will be of assistance, both in extending the known boundaries of deposits already recognized, and also in determining the existence and general extent of new deposits. It would thus appear that exploration by means of magnetometric surveys may also be extended to any other ore deposits in which magnetite or pyrrhotite is known to be an accompanying accessory mineral. The conclusion arrived at in regard to the applicability of the method in exploring for copper and nickel deposits on Texada island, British Columbia, is as follows: In places where the formation is covered with swamps and drifts, the approximate position of pyrrhotite deposits can be determined. It should be remembered, however, that as it is not the pyrrhotite itself but the minerals associated with it, namely, copper pyrite and pentlandite, which make up the chief value of the ore, and as the proportion of these minerals as compared with the pyrrhotite varies considerably, the amount of copper and nickel may be low even when a strong magnetic field is obtained. Hence the discovery of magnetic attraction is by no means to be considered as absolute proof of the existence of a deposit of workable ore. A steady and continuous attraction, though weak, is a good indication that an orebody may be found. Having ascertained the approximate location of a magnetic body by a magnetometric survey, diamond-drilling or some other method of exploring must be used in order to ascertain the quality and character of the deposit. This instrument, which is exhibited in the Swedish Pavilion at the Exposition, has been successfully employed in investigating buried gravel deposits.

A MINERALOGICAL joke was played on a mining engineer during his visit to Korea. Perhaps his assumption of superior wisdom irritated the junior members of the staff of the mine that he was examining. After he had finished his soup the next course was brought on—pieces of something that looked like smoked halibut. He was just going to take a piece from the large platter, held by the deferential Korean servant, when the assistant superintendent, a slender and innocent-appearing Australian, asked: "What do you think that is?" "Some sort of smoked fish," replied the visitor. But to his surprise the fork refused to penetrate the supposed fish, and a closer examination showed that it was a specimen of 'mountain leather,' or asbestos.

No. 1 AND 2 SHAFTS at the Centennial mine, Michigan, were up and down draft, respectively. A fire in No. 2 caused a reversal of draft. This was lucky, or the shaft would have been burned to the bottom.

Aluminum Precipitation at the Mill of the Butters Divisadero Company

By E. M. HAMILTON and P. H. CRAWFORD

Introductory. Before proceeding with the main subject of our article it may be of interest if we give a short summary of the history of aluminum precipitation.

In 1893 Carl Moldenhauer patented the use of aluminum as a precipitant for gold and silver from cyanide solutions, but does not appear to have followed up his idea on a practical scale.

In the same year H. F. Julian experimented with it in the form of plates set vertically in a box, and also in the form of filaments or shavings, but the attempt was not successful, because alumina deposited on the metallic surfaces and stopped all further action.

In 1910 S. F. Kirkpatrick conceived the idea of using the metal in the form of dust and thus avoided Julian's difficulty in regard to the coating of the metallic surfaces with alumina; because in the case of the dust the metal particles are entirely dissolved before any such protecting action can take place.

The fact that aluminum does not replace the precious metals in the cyanogen compound renders necessary the presence of caustic soda or potash, the reaction probably occurring theoretically thus:

$$6NaAgCy_2 + 6NaOH + 2Al = 6Ag + 12NaCy + 2Al(OH)_3$$

The aluminum hydroxide at once dissolves in the excess of caustic to form sodium aluminate,

$$2Al(OH)_3 + 2NaOH = Na_2Al_2O_4 + 4H_2O$$

If this explanation be the correct one it should be possible to make one part of aluminum precipitate 12 times its weight of silver, but in practice the amount is more like 3 times its weight only, so for low-grade solution when caustic and aluminum are both present in excess, the following may more nearly represent what actually goes on:

$$2NaAgCy_2 + 4NaOH + 2Al = 4NaCy + 2Ag + Na_2Al_2O_4 + 4H$$

A description by Hamilton of the introduction of the process at the Nipissing low-grade-ore mill was published in the *Engineering and Mining Journal* of May 10, 1913. It was adopted at that mill at the time of its starting in November 1912, because it was found that with zinc precipitation the zinc taken into the stock solution formed with the arsenic present in the ore a combination inimical to the dissolution of the silver, the substitution of aluminum for zinc showing an increase in extraction of over 4 oz. silver per ton. Since that time its use has been continued with entirely satisfactory results.

In August 1914, G. H. Clevenger presented to the American Institute of Mining Engineers a paper reviewing Hamilton's original article and criticizing certain points in it, to which the latter replied in an article in the *Engineering and Mining Journal* of March 27, 1915. The most important question raised by Clevenger was: "Is the aluminum dust process likely to result in a greater final profit than the use of zinc, at mills where zinc in solution is no detriment to a high silver extraction?" This Hamilton tried to answer in the affirmative, by showing that for a 10-oz. silver ore the additional cost of the process over zinc should not be more than 1c. per ton, against which would be set a saving in cyanide of greater or less amount. Clevenger questioned such a saving on the ground that all or most of the zinc-potassium cyanide formed in the zinc process was subsequently regenerated and rendered available for doing work, and, on the contrary, even suggested a loss of cyanide in the aluminum process due to adsorption by precipitated aluminum hydroxide.

Hamilton, while admitting that a variable amount of the zinc double cyanide formed in the zinc process is usually regenerated later on, denied that anywhere near all of it was so rendered available, the proportion not regenerated forming a measure of the cyanide that might be saved by substituting the aluminum process. He also expressed the opinion that while the adsorption of soluble salts by colloidal substances was an acknowledged fact, yet that the figures at the Nipissing indicated that in practice this tendency was small enough to be negligible, probably because, on account of a high caustic content in the solution, aluminum hydroxide was not precipitated, though there was some precipitation of aluminum as calcium aluminate by the small amount of lime added in the mill.

He agreed with his critic that a full-sized working test of the two processes under similar conditions would be the only way to settle the theoretical questions raised, and the present article is designed to give an account of such a test, made at the mill of the Butters Divisadero Company.

Conditions. It should be stated at starting that the ore being treated at this mill is not one of those in the cyaniding of which zinc in solution is detrimental to extraction, so that the chief advantage to be derived from the introduction of aluminum precipitation lay in the possible saving of cyanide by its use. The assay-value is low, being about $2 in gold and 7 oz. in silver, and as 1 oz. of silver combines with alkaline cyanide to the amount of 0.08 lb. KCy or 0.06 lb. NaCy it will be seen that at this mill the conditions are not as favorable as they might be for displaying the capabilities of the process in the economy of cyanide.

When we began experimenting with a view to its introduction at the Divisadero mill we soon found that some modification in the system used at Nipissing would be necessary in order to make it applicable to this ore, and probably also to the majority of other ores.

It may be well here to remind our readers of the conditions that obtain at Nipissing. The ore is crushed in caustic soda solution in preparation for the desulphurizing process. About 5 lb. of lime per ton is added in the battery to obtain the preliminary settlement of the slime, but most of this is soon thrown out as calcium aluminate by the sodium aluminate in the mill solution, derived from this process. The pulp is then filtered, and, without any water-wash, is discharged, and re-pulped with cyanide solution, agitation following in the usual manner. When treatment is finished the slime settles without trouble, although hardly a trace of lime is left in solution at this stage.

The first condition with which we had to contend at Divisadero was the acidity of the ore, the lime consumption being 30 lb. of high-grade lime per ton. As stated in Hamilton's original article, it is essential that lime shall be absent from solution at the time of precipitation, because it reacts with the sodium aluminate and is precipitated in the press as calcium aluminate, yielding at the clean-up a product that it is almost impossible to melt. The cost of substituting caustic soda for lime as a neutralizer would have been prohibitive, while the plausible alternative of adding just the right amount of lime to insure its being all neutralized by the time the ore-treatment was finished had the drawback that, though neutralized, it would not necessarily all be removed, because calcium sulphate is rather more soluble in water than the hydroxide, and would be equally precipitated by sodium aluminate should it reach the precipitation system.

The second condition that made the Nipissing process inapplicable here was the fact that the slime would not settle satisfactorily without an adequate quantity of lime in solution at the close of ore-treatment, whereas, at the Nipissing, as already stated, the final settlement takes place without trouble in the absence of lime.

New Method. To overcome these difficulties Hamilton devised the plan of treating the solution before precipitation with soda ash, thus throwing out the lime as carbonate and substituting caustic soda therefor:

$$Ca(OH)_2 + Na_2CO_3 = CaCO_3 + 2NaOH$$
$$CaSO_4 + Na_2CO_3 = CaCO_3 + Na_2SO_4$$

After several months experimenting on a large scale we succeeded in developing this idea into a smoothly working process,* which at the time of writing has been running six months and gives entire satisfaction. It allows us to use all the lime necessary for neutralizing and settlement, it yields a lime-free solution for precipitation, and incidentally manufactures the caustic soda necessary for that operation, in accordance with the formula, given above.

The idea at first was to add the soda ash to the slime charge at the end of agitation, so that the precipitate of calcium carbonate might be filtered out with the gangue, avoiding a separate operation; but owing to the slow settlement of the slime, caused by the absence of lime, this plan was abandoned, and it was decided to separate the lime from the clear solution just before precipitation of the gold and silver.

The solution derived from slime treatment, including that decanted before filtration and also the effluent from the Butters filter, amounts to four times the weight of slime treated, and is all precipitated, but part of it is first used for the treatment of the sand in the leaching plant and by this considerably enriched in gold and silver. As the ratio of sand to slime is about 1 : 1 the ratio of solution precipitated to ore milled is 2 or 2.5 : 1. The method of operation is as follows: The pregnant solution is pumped to a tank of 100 tons capacity, above the plant, fitted with a mechanical stirring-gear, and it is here that the soda ash is added. In order to find out exactly how much of the latter is needed, a simple test is employed. A standard solution of the soda ash is prepared by dissolving 6.25 grams in distilled water and making up to 1 litre, and is such that if 50 c.c. of pregnant solution be taken for the test, each cubic centimetre of soda ash solution will be equivalent to $\frac{1}{4}$ lb. of the dry salt per ton of cyanide solution. A portion of the solution to be tested is filtered, and 50 c.c. measured and placed in an Erlenmeyer flask or small beaker and heated over an alcohol lamp until almost too hot to hold in the fingers. A measured quantity, say, 2 c.c. of the soda ash solution is then drawn from a burette and agitated for a few minutes to insure complete precipitation. The contents of the flask are filtered, and the filtrate divided into two parts; to the first part is added a few drops of potassium oxalate solution, and if any turbidity results it indicates an insufficiency of soda ash. In that event a fresh portion of the original solution is taken and the test repeated, increasing the soda ash to 2.5 or 3 c.c., filtering, and testing with oxalate as before. This operation is repeated, if necessary, until no turbidity is produced on adding oxalate. When a test is secured in which no lime is indicated, the second portion of the filtrate is tried for excess of soda ash, by adding a few drops of calcium chloride solution. If no turbidity is produced, the required quantity has been found, and the number of cubic centimetres of soda ash solution multiplied by 0.25 and by the number of tons of solution in the tanks gives the amount of ash in pounds to be added to the charge. Should the addition of calcium chloride, mentioned above, indicate that there is an excess of soda present, the original test may be repeated, using 0.5 c.c. less of the standard soda solution.

A slight excess of soda ash seems to be unimportant, but it is essential that no lime should be indicated.

It usually takes from 10 to 15 minutes to ascertain the amount of ash needed for a charge, and when this has been done the required quantity is placed in a screened drum hanging under the inflow pipe, and the pump and agitator started. By the time the tank is filled to the

*Patented on April 20, 1915.

required tonnage mark the reaction is complete and the charge is allowed to settle, the clear solution being then decanted to a sand-filter clarifier, whence it passes to the precipitation house. The turbid remainder is afterward stirred and run through a valve in the bottom into a smaller tank below fitted with a filter-bottom connected to a vacuum-pump; here the carbonate of lime settles and allows of a further decantation of clear solution to the sand-filter. The result of several days' operations is allowed to accumulate in this filter-tank, and finally the vacuum is turned on and the precipitated lime filtered to a firm cake. After a water-wash, to remove pregnant solution, the deposit is shoveled into empty cyanide tins and allowed to dry in the air for a few days, and then charged back into the lime-kiln to be re-burnt and used over again.

We have now followed the solution to the stage where

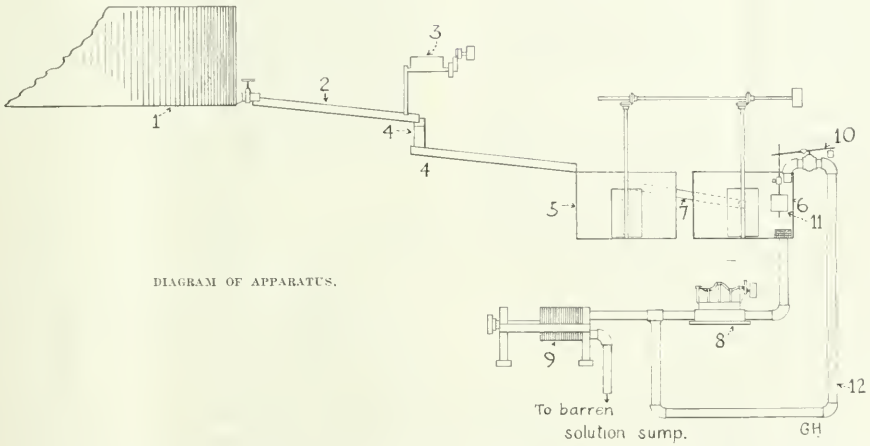

DIAGRAM OF APPARATUS.

it is ready for aluminum precipitation, and from this point onward its progress conforms with the method in use at Nipissing, but for the sake of those who have not read Hamilton's original article on the subject we give herewith a short sketch of the subsequent treatment.

The solution after leaving the clarifying filter passes down through a covered launder to the precipitation tanks. In this launder is added the aluminum dust, through a worm-feeder whose speed is adjusted by means of a pair of cone-pulleys. When it nears the precipitation tanks the continuity of the launder is broken twice, allowing the solution a clear drop of 6 inches each time, to assist in wetting the dust.

Referring to the diagram, (1) is the clarifying filter, (2) the launder, (3) the aluminum-dust feeder, (4) interruptions in the flow of solution, (5) and (6) the precipitation tanks. These latter are 6 ft. in diameter and 4 ft. deep, and are fitted with mechanical stirring-gear driven by the bevel-wheels and horizontal shaft above. To the vertical shafts are bolted boards 10 in. wide and 1 in. thick, extending from the bottom to within 12 in. of the top of the tank, and these shafts make 60 r.p.m. (7) is a 6-in. pipe connecting the two tanks; it extends almost to the bottom of (5), and after passing through the side near the top it slopes down somewhat and discharges into (6). It will be seen from this that the solution in tank (5) is maintained at a constant level, while the level of that in (6), though normally constant, can be varied at will, by raising or lowering the float (11) on the rod operating the automatic cut-off valve (10). (8) is a triplex 7x7-in. plunger pump running at 29 r.p.m. and drawing through a 5-in. pipe from tank (6), discharging into the filter-press (9). (12) is a 2½-in. by-pass line in the delivery of the pump, and its discharge is regulated by the automatic float-valve (10). Should the supply of solution from the clarifier be slackened off the level of solution in (6) would tend to fall, thus opening valve (10) and allowing the surplus solution passing the pump to return to the tank, in this way maintaining a constant level. The importance of this lies in the necessity of keeping the pump-suction water-sealed and preventing the entry of air. The operation of precipitation being a reducing one, the presence of air tends to retard it; moreover the silver precipitate formed by aluminum dust is so sensitive to re-solution influences that air in juxtaposition with cyanide solution will often cause metal to re-dissolve in the filter-press itself.

An appreciable period of time is needed to obtain complete precipitation by aluminum dust, and we usually allow from 15 to 20 minutes. A considerable variation in the length of time available may be obtained with this appliance by raising or lowering the level of solution in tank (6), which is effected, as already pointed out, by adjusting the height of the float (10) on the vertical rod.

There is also on the pump-delivery a pressure-gauge, and a relief-valve (not shown in the diagram) set at 80 lb., and discharging back into tank (6).

The filter-presses, of which there are three, are of the ordinary square-frame type used for cleaning-up. They are usually all in use at one time, but are cleaned-up one by one while the flow through the other two is temporarily reduced. In engaging an empty press the inlet-valve is partly closed so as to distribute the stream

of emulsion evenly between the three. The total filtering area available is 627 sq. ft. and this suffices for about 600 tons of solution daily.

The effluent from the presses unites in an iron drum, from which it flows to the barren sump. At this drum is kept a bottle of sodium sulphide solution, and when the shift-man makes his round every hour or so he takes a sample of the effluent and tests it for silver by adding a few drops of the sulphide. Should it show any trace of silver, and he finds on examination that the feeder is working satisfactorily, he slightly increases the flow of aluminum dust.

If a press is left idle for a few hours, or has just been cleaned-up, the effluent will always carry some re-dissolved silver, and to prevent this from salting the barren sump it is diverted to the pregnant sump for 5 to 10 minutes, or as long as may be necessary.

The precipitate obtained by this process is bulky and porous; it has a rich brown color, and melts readily with a minimum of flux. On an average it contains about 85% of precious metals, and when melted yields bullion 980 fine.

Results. During the period covered by the following data the cyanide used was sodium, 130%, costing 21c. per pound laid down at the mine, the cost of zinc was 7.2c. per pound, of aluminum dust 26c., and of soda-ash 2.4c. The aluminum precipitation figures represent averages over three consecutive months, during which the total quantity of ore crushed and cyanided was 28,100 tons. For comparison in zinc precipitation, three recent consecutive months have been taken, the total tonnage being practically the same.

Zinc

(Tons treated, 28,200)

	Total, lb.	Per ton, lb.	Total cost.	Cost per ton.
Cyanide	62,400	2.21	$13,104	$0.464
Zinc	29,816	1.05	2,146	0.076
Total	....	...	$15,250	$0.540

Aluminum

(Tons treated, 28,100)

	Total, lb.	Per ton, lb.	Total cost.	Cost per ton.
Cyanide	38,068	1.35	$7,994	$0.284
Aluminum	7,700	0.27	2,002	0.071
Soda-ash	43,013	1.53	1,032	0.036
Total	....	...	$11,028	$0.391

Thus, although the cost of aluminum and soda was 3c. more than the cost of zinc, yet the aluminum showed a saving of $4222, or 15c. per ton.

The bullion precipitated during the two periods was for the zinc process 134,628 troy ounces of fine gold and silver, and for the aluminum 173,660 oz. During the latter period the grade of ore was somewhat higher, and also the percentage of extraction, which accounts for the greater quantity of bullion recovered.

It is worthy of note that the actual difference in cyanide consumption of 0.86 lb. per ton in favor of aluminum is considerably more than that theoretically demanded by the quantity of silver dissolved. With a head value of 7 oz. and an extraction of 87% we should have 6.09 oz. per ton of ore going into solution, and since 1 oz. of silver combines with an amount of cyanogen equivalent to 0.06 lb. sodium cyanide, the amount of cyanide to be recovered from this source would be only 0.36 lb. per ton of ore.

There is a small quantity of copper dissolved, and at first sight it might seem as if the unaccounted increase in cyanide might be derived from the copper-cyanogen compound, but we have found, both here and at Nipissing, that copper is very difficultly precipitated by aluminum dust, and that under normal conditions hardly any is thrown down. As an illustration of this we may quote the following, which is one of the preliminary experiments made here before the introduction of the process. In this experiment 80 lb. of average battery ore was ground to a slime and agitated with freshly-prepared cyanide solution. After treatment this solution was precipitated with aluminum dust and used over again for another extraction test on similar ore. This was repeated four times, and each time, before precipitation, a portion of the solution was tested for sulphocyanate, ferrocyanide, and copper.

	1st time, %	2nd, %	3rd, %	4th, %
KCyS	0.023	0.05	0.08	0.113
K_4FeCy_6	trace	0.02	0.06	0.06
Cu	trace	0.006	0.009	0.014

The copper is here shown as gradually building up in strength each time the solution was re-used, indicating that precipitation, if any, was very slight. In the light of the recent working figures it is a matter for regret that copper determinations were not made both before and after precipitation, but this will doubtless be done on the working solutions in the near future.

Another possible but improbable theory is that the additional cyanide might be derived from the decomposition of sulphocyanate. We say "improbable" because in laboratory tests we have failed to break up KCyS in weak solutions (0.05 to 0.15% KCyS), though Clennell in a private communication states that by agitating with aluminum dust a concentrated solution made strongly alkaline with caustic soda he has succeeded in forming sodium sulphide, indicating a decomposition of sulphocyanate, but without any appreciable formation of free cyanide.

So far as we have gone at present, therefore, the source of the additional saving in cyanide is undetermined.

A point of interest in connection with this process is that, in the act of precipitation, there is usually a tendency to form soluble sulphide, probably by reason of the decomposition of thiosulphates. This tendency is not strongly marked at Divisadero, and, while traces of sulphide may often be found by testing the effluent of the press with a lead salt, they are never apparent in the barren sump, doubtless having been oxidized by contact with air during the passage of the solution thither. At the Nipissing soluble sulphide was found in considerable

amount, not only in the precipitating-press effluent, but also in the barren sump. To counteract this a drip of lead acetate into the stream was tried for a time, but as the presence of lead in solution was found to be detrimental to the extraction of the silver from the ore, this was soon discontinued, and, instead, an air-lift was placed in the barren sump to render the sulphide harmless by oxidation. This it accomplished rapidly, and no bad effects were ever noticed in the extraction treatment as a result of the formation of sulphide in precipitation. At Divisadero the question of soluble sulphide is ignored and no special preventive measures are taken. A small quantity of litharge and lead acetate is used during extraction, but this was proved advantageous when zinc was the precipitant and it has not been found necessary to increase the amount since the adoption of aluminum.

Conclusion. From the results given it will be apparent that there is no question of the saving in cyanide effected by aluminum precipitation, and that if there is any adsorption of the salt by precipitated alumina it is a negligible quantity as compared with the amount liberated for future use. Although at the prices of reagents current before the War the cost of aluminum precipitation is slightly higher than that of zinc, yet the introduction of the process here has been amply justified by results, and Mr. Charles Butters is to be congratulated for having allowed the experiment to be continued, in spite of the rather discouraging appearance of the process during the first two or three months, due to the difficulties and setbacks almost always encountered during the installation and development of new methods.

The Mnemonic system of filing papers employs twenty-three letters of the alphabet, thus having an advantage over the Dewey system, which employs decimals. The aim of the mnemonic system is to make each letter the initial of the term symbolized, hence it can be more easily remembered than an arbitrarily chosen number. In classifying the correspondence of a telephone company, for example, the divisions would be: C, Construction; E, Equipment; F, Finance and accounts; G, General; P, Operation; R, Rates; X, Executive. Construction will be subdivided thus: CC, Circuits, loops, phantoms, etc.; CK, Cables; CL, Pole-lines; CN, Conduits; CP, Poles, wires, etc.; CR, Real estate; CV, Private lines. Real estate may be classed under: CRC, Construction of new buildings; CRM, Maintenance of real estate; CRP, Purchase of property. Construction of new buildings will require: CRCC, Contracts; CRCN, Interior appointments; CRCP, Plans and specifications. Interior appointments need: CRCNF, Furnishing; CRCNH, Heating-plant; CRCNL, Lighting. Classification of lighting in detail: CRCNLE, Electric wiring; CRCNLG, Gas fixtures; CRCNLL, Oil; several kinds of oil will be shown by: CRCNL1L, CRCNL2L.

Alunite. Probably the most remarkable deposit in the world is a low bluff ridge, composed entirely of this material in the county of Gloucester, New South Wales. In 1912 the exports were 3425 tons valued at $68,500.

Crushing at the Tonopah-Belmont Mill

The crusher-plant has a capacity of about 100 tons per hour, and is operated only one 8-hr. shift per day. It is driven by one 100-hp. motor on crushers and trommel, one 20-hp. on waste-conveyor, one 7.5-hp. on grizzles and undersize-belt, one 20-hp. on inclined-belt, and one 15-hp. on horizontal battery-bin belt and automatic-tripper, a total of 162.5 hp. The actual power consumption, under full crushing load, is 80 horse-power.

Concaves for the No. 4 short-head crushers weigh 677 lb., cost $88, and last two years, crushing about 75,000 tons. These concaves are used about six months, are then set out, re-babbitted, and used for six months longer, when they are turned end for end and give another 12 months' service. The No. 4 mantle weighs 536 lb., costs $132, and has a life of two years, crushing about 75,000 tons.

Concaves for the No. 7½K crusher last about one year and crush about 150,000 tons. They weigh 1120 lb. and cost $202. The No. 7½ mantle weighs 1994 lb., costs $353, and lasts 18 months, crushing about 225,000 tons.

The manganese-steel trommel-screen weighs 3776 lb., costs $572, and lasts two years, handling 300,000 tons.

The consumption of wearing parts in the crusher-plant is 0.0325 lb. per ton of ore, at a cost of $0.00555.—A. H. Jones in Bulletin 104 of the A. I. M. E.

Waste in Mining

The losses sustained in other countries from lack of care and thought in this respect are enormous. Dr. James Douglas estimates, for instance, to take only one example, that at the Rio Tinto mines in Spain in a period of some 30 years, through the unskilful treatment of the ore, about 7,000,000 tons of sulphur, valued at not less than $70,000,000, was wasted, while with modern improvements in the method of handling the ore, about 1,000,000 tons of sulphur are annually saved to the world which would otherwise have been burned and served simply to pollute the atmosphere. He also points out that only about 60% of the hundreds of millions of dollars yielded by the Comstock lode was extracted at the time, and at first the rich tailing was not even collected, such was the haste of the miners to deplete that stupendous deposit which should have made Nevada prosperous for generations instead of whirling the whole country into a mad dance of reckless speculation.

The primary cause of a large part of this waste is over-capitalization, which involves a large output at any expense, if the value of the shares is to be raised and their price maintained. Over-capitalization generally demands over-production, which in its turn almost invariably involves waste at some stage of the progress of the metal from the mine to the consumer.

Combustion may be defined as the chemical union of combustible matter with oxygen, the supporter of combustion.

Methods of Paying for Metal Contents of Ores

By CHARLES H. FULTON

*No metallurgical process recovers all the metal in the ore, hence payment for all the metal cannot be expected. A deduction is made from the metal-content to allow for loss in treatment.

LEAD may be determined in two ways: (1) By wet analysis, which gives the actual amount of lead in the ore; (2) by fire-assay, in which the lead content is determined by fusion in a crucible. Fire-assaying may be considered smelting on a small scale. Therefore the smelter buys lead in ores on the basis of the fire-assay, as the results represent, in theory, the lead that he may expect to recover.

For ores that contain no appreciable proportions of easily reducible metals, like copper, antimony, and bismuth, or like zinc and arsenic, aside from the lead, the fire-assay gives results that are lower than those obtained by the wet analysis. The difference is usually about 0.5 to 0.9%; that is, an ore showing 35% lead by wet analysis gives 34.1 to 34.5% by fire-assay, or 700 lb. per ton by wet analysis and 682 to 690 lb. by fire-assay. On ores containing appreciable proportions of the metals mentioned above, the fire-assay often gives higher results than the wet analysis, as some of the metals are reduced with the lead, but these fire-assay results, of course, are incorrect. It follows, therefore, that in buying 'pure' ores, or those not containing easily reducible metals other than lead, the smelter wants to buy on the basis of the fire-assay, but when buying 'impure' ores, or those containing other easily reducible metals, he wishes to buy on the basis of the wet analysis, with a deduction to cover the loss in smelting. On the other hand, the position of the miner is reversed. He desires to sell 'pure' ores on the basis of the wet analysis and 'impure' ores on the basis of the fire-assay.

In order to adjust these difficulties the following practice has been adopted: For pure lead ores, such as are produced in the Coeur d'Alene district, Idaho, the fire-assay is still used to determine the amount of lead, although both mining and smelting companies check the results by wet analysis. In other instances, as in Utah, it is customary to make a fire-assay and then determine the lead in the fire-assay button by wet analysis and call the result the amount of lead in the ore. In still other instances a wet analysis is made for lead, and a deduction of 1, 1.3, or 1.5% is made from the result to give the 'dry assay', the equivalent of the fire-assay. For example, if an ore gives a content of 20% lead by wet analysis, the dry content will be 19 to 18.7 or 18.5% dependent on the deduction agreed upon. In short, an effort is made to determine the percentage of lead in the ore that is recoverable by the smelting operation.

The question arises whether the results obtained by fire-assay correspond to the yield in smelting. The losses in lead smelting, exclusive of those connected with refining, may be stated as ranging from about 4.5 to 17% of the lead smelted, as determined by wet analysis. Such losses include the loss incurred in roasting a fair proportion (35%) of the charge. The low figure applies to the smelting of a furnace-charge high in lead, that is, a charge, considered as a whole, that contains about 30 to 35% lead, whereas the high figure applies to furnace-charges low in lead, say somewhat less than 10%, or to charges that contain a large percentage of roasted material. The loss in normal smelting, or with 10 to 15% lead on the charge, is 8 to 11%. Therefore, an ore containing 35%, or 700 lb., of lead per ton, or 682 lb. by fire-assay, will yield in the normal furnace charge 89% of its contents, or 623 lb., a loss of 77 lb., or 59 lb. more than the fire-assay indicates. In the same way a deduction of 1.5% from the lead content of this grade of ore does not cover the smelting loss. On the other hand, if an ore contains 10% lead by wet analysis, or 200 lb. per ton, and the smelter pays for 10 – 1.5%, or 8.5%, or 170 lb. per ton, and he again recovers 89%, or 178 lb., it is obvious that his deduction more than covers his smelting loss.

It is therefore generally true that the fire-assay basis or its equivalent, the dry-analysis basis (wet analysis less 1.5%), does not cover smelting losses for medium or high-grade ores, but somewhat more than covers smelting losses for low-grade ores, provided a furnace-charge containing not less than 12% lead can be made.

In order to safeguard himself, the smelter makes an additional deduction to cover loss in smelting. The procedure in Utah is as follows: The smelter pays for 90% of the lead content, either determined by fire-assay or put on the dry-analysis basis; that is, lead determined by wet analysis less 1.5%. When this additional deduction is made, the total deduction more than covers any loss, as per the following example: In an ore containing 35% or 700 lb. of lead by wet analysis, or 682 lb. by fire-assay, payment will be made for 90% of 682 lb., or 613.81 lb. The loss in smelting this ore under the conditions already described will be 77 lb., or 9.2 lb. less than the deduction made. Again, as the grade of the ore decreases, the deductions made will become considerably greater than the actual losses.

In Colorado no special additional deduction is made, but its equivalent is obtained by paying less for the lead.

COPPER CONTENT is determined by wet analysis, either electrolytically or else volumetrically by iodide or cya-

*Abstract from 'The Buying and Selling of Ores and Metallurgical Products,' Technical Paper No. 83, U. S. Bureau of Mines.

nide method. In Michigan the fire-assay is still used for metallic copper concentrate or 'mineral.' The smelter desires to obtain a figure representing the 'yield,' as this theoretically corresponds to what he recovers in smelting and is all that he can be expected to pay for. Hence the copper paid for is the 'dry' copper, that is, the actual amount of copper as determined by the wet assay less a standard deduction for changing to dry basis. This deduction is usually either 1, 1.33, or 1.5%, but occasionally may be as low as 0.75%. Naturally, therefore, when the copper content of an ore is less than 1.5 or 1%, it is not paid for. When a contract specifies that the copper content on the basis of a dry analysis is equivalent to "wet less 1.5%," it means that if an ore contains actually 12.5%, or 250 lb. per ton, payment will be made for only 220 lb., the difference, or 30 lb., representing loss in smelting.

Usually the placing of the copper content on the dry basis fully covers any smelting losses sustained. According to the grade of the ores smelted, copper losses vary from 5 to 15%, the higher figure applying to ores of lower grade.

Gold and Silver. The deduction for loss in extracting gold and silver is made somewhat differently. Often the deduction for smelting loss is 5% of the gold content and 5 to 10% of the silver content. Thus a contract may read: "Gold will be paid for at 95% of the assay at $20 per ounce. Silver will be paid for at 95% of the assay at New York quotations." In other instances, in place of making a percentage deduction from the assay to cover loss, the price paid will be decreased to $19 per oz. for gold. Gold in an ore is usually not paid for if less than 0.03 oz. per ton is present, and silver if less than 1 oz. per ton. This is due to the fact that in a smelting mixture giving a certain type of slag the slag will retain a fixed amount of metal. In smelting low-grade ores the proportion of loss is much greater than in smelting high-grade ores.

Cost of Freight and Refining. So far the charges for smelting the ore and the deductions for loss of metal have been considered. There still remains to be added the cost of freight to the refining centre and of refining the metal in the crude product, so that it may be placed on the market. This charge is imposed by paying for the metal-content a lesser price per pound or unit than the quotation for refined metal. Thus copper in ore may be paid for at the New York quotation on electrolytic copper, on the date of assay, less 3 cents per pound, this 3 cents covering the refining, freight, and selling charge. Sometimes copper is paid for on the unit basis, for instance, $2.80 per unit of 20 lb. With refined copper at 17c., this is equivalent to a deduction of 3c. per pound.

This method, however, is not common for copper ores because it leaves out of consideration the fluctuations in copper prices and places a fixed value on the copper content of the ore during the terms of the contract. Lead in ore is more frequently bought on the unit basis, the price per unit varying with the sales price of the metal at New York. The price paid per unit of lead is always less than the value of 20 lb. of lead at prevailing lead prices. Thus lead may be paid for at 50c. per unit when the price of lead in the market is 4c. per pound. This rate means a deduction of 30c. per unit or 1.5c. per pound to cover refining and freight charges. When copper and lead in ores are bought on a unit basis, payment is usually made on a sliding scale, higher prices being paid per unit on ores that are high in metallic content.

Payment for lead in ores, after the percentage has been determined by fire-assay, or by wet analysis less either 1 or 1.3 or 1.5%, is made according to one of three methods:

1. By the unit and at quotation, a system used chiefly in Colorado.

2. For 90% of the lead content at the sales price, with a deduction per pound, a system used chiefly in Utah.

3. For 90% of the lead content at 90 or 95% of the sales price, a system used for Idaho ores.

Following are examples of payment by the unit-and-quotation system. The smelter pays for 'wet' lead, less 1.5%, as follows:

Lead content, dry basis, %	Price per unit.	Lead content, dry basis, %	Price per unit.
5 to 10	$0.35	25 to 30	$0.49
10 to 15	0.40	30 to 35	0.51
15 to 20	0.45	Over 35	0.51
20 to 25	0.47		

Unit equals 1%, or 20 lb., per ton.

The price per unit is based on what is called a 'quotation' of $4 per 100 lb. of lead. For every rise or fall of 5c. in the quotation 1% is added or deducted from the price per unit. The quotation is not the sales price in New York, but is determined as follows: If the sales price in New York is $4 per 100 lb., the quotation taken is 90% of this price, or $3.60. If the sales price is more than $4 and not above $4.50, the quotation is obtained by taking $3.60 and adding to it one-half of the excess of the sales price over $4. If the sales price is more than $4.50, the quotation is obtained by taking $3.60 and adding to it half the excess of the sales price between $4 and $4.50 and all of the excess above $4.50.

As a concrete example of payment by the unit-and-quotation system, suppose the sales price in New York is $4.30 per 100 lb. The quotation will then be determined as follows: $3.60 + ½ ($4.30 − $4.00) = 15c., or $3.75.

In the case of an ore containing 35% lead, for which, according to the table, 51c. is paid per unit on the basis of a $4 quotation, the price will become 51c., less as many cents as there are 5-cent units in the difference between $4 and the new quotation of $3.75. The difference is 25c.; therefore a deduction of 5c. per unit is made from 51c., and the actual price per unit paid is 46 cents.

By way of further example, suppose the sales price in New York is $5 per 100 pounds. The quotation will then be as follows: $3.60 + ½ ($4.50 − $4.00) + ($5.00 − $4.50), or $4.35. For a 35% ore for which 51c. per unit is paid on a quotation of $4, the price per unit will become 51c. + ⅕ ($4.35 − $4.00), or 58 cents.

Question. If a miner has a ton of lead ore that contains 36.5% lead by wet analysis, and the sales price of

lead in New York is $4.30 per 100 lb., what would be the value of this lead in New York, and what does he receive for it from the smelter?

Answer. The ore contains 730 lb. lead, which, at $4.30 per 100 lb., amounts to $31.39. The miner is paid for 35% lead at 46c. per unit, or $2.30 per 100 lb., a total of $16.10. The difference is $15.29. Of course, the miner is in no sense entitled to the full value of his lead, for certain losses and charges must be deducted; however, it is not just to make too great a deduction.

Under the method of payment on the basis of 90% of the lead content at the sales price, with a deduction per pound, the lead content is determined by the fire-assay, or by the wet method less the deduction of 1 or 1.3 or 1.5%. Ninety per cent of the lead thus determined is paid for if more than 5% lead be present; if the proportion be less, it is not paid for. The lead is paid for at the New York sales price, less a deduction of 1.5% per pound, if the lead content of the ore is less than 25%; a deduction of 1.25c. per pound is made if the lead content is more than 25%.

Question. If a miner has a ton of lead ore that contains 36.5% lead by wet analysis and the sales price of lead in New York is $4.30 per 100 lb., what would be the New York value of this lead to the miner and what does he receive for it from the smelter?

Answer. The ore contains 730 lb. lead, which, at $4.30 per 100 lb., amounts to $31.39. He is paid for 90% of 35% (36.5 less 1.5%) of lead, or 630 lb., at the rate of 4.3c., less 1.25c., or 3.05c. per lb., which amounts to $19.21. The difference is $12.18.

Under the method of payment for 90% of the lead content at 90 or 95% of the sales price, the lead content is determined by the fire-assay or by the wet method less the deduction of 1 or 1.3 or 1.5%. Ninety per cent of the lead thus determined is paid for at 90 or 95% of the sales price in New York as may be agreed upon. Lead in an ore, if less than 5%, is not paid for.

Question. If a miner has a ton of lead ore that contains 36.5% lead by wet analysis, and the sales price of lead in New York is $4.30 per 100 lb., what would be the value of this lead in New York and what does he receive for it from the smelter?

Answer. The ore contains 730 lb. of lead, which, at $4.30 per 100 lb., amounts to $31.39. He is paid for 90% of 35% (36.5 less 1.5%) of lead, or 630 lb., at 90% of $4.30, or at the rate of $3.87 per 100 lb. This amounts to $24.38. The difference is $7.01.

A comparison of the rates under the three methods for the three examples presented is given below:

Method of payment	Quantity of ore tons	Lead content %	Gross ore value	Paid to miner	Value to smelter
By the unit, and at quotation	1	36.5	$31.39	$16.10	$15.29
On basis of 90% of lead content at sales price, with deduction per pound.....	1	36.5	31.39	19.21	12.18
On basis of 90% of lead content, at 90 to 95% of sales price	1	36.5	31.39	24.38	7.01

Evidently the first system gives the least return on the lead. In this connection the reader should note, however, that the contract as a whole must be considered. For instance, under the first system, treatment charges are much lower than under the third system, so that the net outcome to the miner may be about the same on the same kind of ore under any of the systems.

In certain instances the smelter absorbs part of the rise in price of lead when the sales price goes above a certain figure. Thus, if the sales price in New York is $4 or less, the smelter pays at the rate of 90% of the sales price. But if the sales price rises to a figure between $4 and $4.50, the smelter will not pay at the rate of 90%, but will pay for only 90% of $4 plus one-half of the excess of the sales price over $4. If the price is above $4.50, it will pay for 90% of $4 plus one-half of the excess between $4 and $4.50 and all the excess above $4.50. As an example, if the sales price in New York is $4.80, the miner, on the basis of 90%, should receive $4.32. Actually he receives on the modified basis 90% of $4, or $3.60, plus ½ ($4.50 – $4) plus ($4.80 – $4.50), or $4.15 per 100 lb. The difference of 17c. per 100 lb. is absorbed by the smelter.

A feature of most schedules is that they do not provide for payment for a lead content of less than 5%. In some instances a lead content of less than 5% is paid for at the same rate as the bonus is granted on iron, namely, at 15c. per unit, as against the rate of about 40c. per unit usually paid for lead when present in low percentages. Another feature is that the price per unit paid for the lead in ores of low lead-content is less than that for ores of high lead-content. In the same way under the second system the deduction per pound is greater for ores of low lead-content than for ores of high lead-content. This difference is perhaps justifiable from the smelters' standpoint in that the losses are comparatively greater in smelting low-grade ores than in smelting high-grade ores.

PAYMENT FOR COPPER IN ORES, the percentage being determined by wet analysis, less 1, 1.3, or 1.5%, as the case may be, is made on the basis of the New York price of refined copper less a deduction to cover the cost of refining and freight of the metal to the market. The quotations in New York are made on three brands of copper as follows: (*a*) Electrolytic copper in the form of ingots or wire-bars; (*b*) electrolytic copper in the form of cathodes, that is, the electrolytically deposited copper in its original form previous to melting, and (*c*) casting copper, or copper not electrolytically refined and only reasonably pure. Cathodes are usually quoted at about 0.1c. less, and casting copper at 0.2c. less than wire-bars. The amount of the deduction from the market-price is given in the accompanying table.

It will be noted that the deduction on lead ores containing copper is greater than on 'straight' copper ores, the reasons being as follows: When copper is present in an ore that goes to make part of a mixture smelted in the lead blast-furnace, the aim of the metallurgist is to recover this copper in the form of a matte. The liquid

Kind of ore.	Dry copper content of ore, %	Deduction per pound.
Lead ore containing copper	1.5 to 5	6c. off casting-copper quotation.
	5 to 10	5c. " " " "
	More than 10	4c. " " " "
Copper ores	1.5 to 5	5c. " electrolytic-copper "
	5 to 10	4½c. " " " "
	10 to 20	4c. " " " "
	20 to 30	3½c. " " " "
	More than 30	3c. " " " "

Dry copper content represents content as determined by wet analysis less ½%.

products that flow from the furnace are (1) lead, which contains alloyed with it gold and silver and a varying proportion of such impurities as bismuth, arsenic, antimony, small amounts of sulphur, and some copper; (2) matte, a sulphide of iron, copper, and lead containing some silver and a little gold; (3) slag, which is the molten refuse of the furnace, composed of the gangue, or worthless material of the ore. This slag always carries away with it a certain proportion of the valuable metals—lead, copper, gold, and silver. These three products have decidedly different specific gravities, so that they can be readily separated, the lead, or heaviest, being separated in the furnace, whereas the slag, or lightest, is sparated from the matte in a settling chamber directly in front of the furnace. The slag goes to waste and the matte is saved.

The formation of matte is due to the presence of sulphur in the charge, and the amount produced is in direct proportion to the amount of sulphur present. If no sulphur were present, no matte would be formed, and any copper in the furnace-charge would enter the lead. This result would be undesirable, because the refining of lead containing considerable copper is costly and wasteful. If too much sulphur be present too much matte will be formed, in turn taking up a large quantity of lead, and making the refining of this product costly and wasteful. The real object, therefore, in forming matte is to throw the greater part of the copper present in the furnace charge into a separate product from which it can be more easily recovered.

The matte produced in the lead-furnace is different from the matte produced in copper-smelting in that it contains some lead, as well as copper. Its treatment for the recovery of the metals in it is consequently more costly than that of a copper-matte, and this fact is reflected in the deductions made from the price of copper in lead ores as against those made from the price of copper in copper ores. Copper in lead ores is usually paid for at market price less 4 to 5c. per pound, whereas copper in copper ores is paid for at market price less 2 to 3c. per pound.

Penalties are added to the smelting-rate on account of the presence in the ore of certain undesirable substances. The matter of penalty for excess silica has been discussed rather fully. The reason for the payment of a bonus for iron has been mentioned. Substances, the presence of which is commonly penalized, are zinc, sulphur (in lead smelting), arsenic (sometimes loosely called speiss), and antimony.

The zinc in the ore is not recovered in the process of lead or copper smelting, but passes partly to the slag and partly into the fume and flue-dust. The slag may contain as much as 8 or 10% zinc without much detriment, but when the proportion is greater, the slag becomes viscid, decreasing the furnace-capacity and increasing slag-losses. In the fume, zinc causes trouble by incrustations in the furnace and by increasing losses by volatilization. Hence a limit of 10% zinc is usually placed on ores, and every unit (20 lb.) per ton above this amount is penalized at the rate of 30 to 50c., the penalty charge thus obtained being added to the smelting-rate. This penalty is so heavy that in dressing ores there is a decided incentive to separate the zinc minerals into a distinct product whenever possible, thus avoiding the penalty on zinc in the lead and copper product, and at the same time obtaining a saleable zinc product that may be sold to the zinc smelter.

A sulphur content greater than 3% is penalized in lead smelting. It is customary to impose a penalty of 20c. on each unit of sulphur in excess of 3. In lead blast-furnace smelting, only a small percentage of sulphur is permissible in the charge, and ores high in sulphur must first be roasted. The roasting entails considerable expense, which is met by the imposition of a penalty on the sulphur content, this penalty being added to the smelting charge. In copper smelting, sulphur is desirable rather than otherwise and is not penalized.

Arsenic is commonly penalized in lead smelting and, occasionally, in copper smelting. Penalty is usually imposed on an arsenic content greater than 1 unit. The presence of arsenic in the lead blast-furnace charge causes the formation of an artificial arsenide of lead, iron, and copper, known as speiss, a most undesirable by-product and costly to treat for the recovery of the contained metals. Its undesirable qualities usually become apparent in the refinery. If arsenic be present in the furnace charge in small amounts, it will pass into the lead bullion, making this difficult to refine.

Antimony causes difficulties somewhat similar to those occasioned by arsenic, but is recovered in the refinery in the form of antimonial lead, which is a saleable product, so that a penalty is rarely imposed on antimony in lead-smelting operations.

The limits set for the occurrence of undesirable constituents vary much in schedules and contracts. Thus it is by no means standard that 3% represents the upper limit of sulphur content in lead ores, so as to be free from penalty. Occasionally penalty is imposed on a sulphur content greater than 1%, and again it may not be imposed until 6% is reached. The same remarks apply

to zinc and other substances subject to penalty. Neither are the prices charged per unit uniform or standard. Limits and prices are usually subject to agreement between the ore seller and the smelter.

Margins. It is apparent from the foregoing discussion that the deductions made for the smelter from the gross value of the ore is much more that the smelting charge alone, for it consists of that charge, plus the deductions resulting from the lesser price paid for the metals, the lesser amount of metal paid for, and the penalties. The smelter also deducts the freight-rate on the ore and makes settlement for this with the railroad company.

In discussions of the smelter business, the term 'margin' is often used; it may be briefly defined as the difference between the actual value of the ore to the smelter and the amount paid to the shipper. What is paid the shipper is the difference between certain credits and debits, the credits consisting of the sum due on metals at the agreed amounts and prices as per contract, and the bonus allowance on iron or lime; the debits consist of the freight and treatment charges and the penalties imposed. The difference is the net amount paid the shipper.

The gross value of the ore to the smelting plant, if this be of the ordinary type, not refining its own product, is the total metal content (100%) at a certain price per metal which is arrived at by taking the market quotation for the metal and subtracting from this a sum to cover the refining charge and the freight of the metal to the market. For example, if copper is quoted at 16.3c. per pound at New York, a Western smelting plant will figure copper to be worth 14.7c. at the plant, the difference, 1.6c., being allowed to cover refining and freight to market. In the same way, with lead quoted at 4.35c. at New York, a certain smelting plant will figure lead to be worth 3.34c. to itself at the plant, the difference of 1.01c. covering refining and freight. Similar allowance is made for the cost of recovering and refining silver and gold.

The gross value of the ore, determined as outlined above, less the net amount paid the shipper, is the margin on the ore to the smelting plant. This margin is the amount that the smelter has to cover his cost and profit and loss. As he has charged himself with 100% recovery, the loss of metal in smelting will appear as a charge against the margin. In calculating the final outcome to the smelting plant it is again desirable to consider debits and credits, the margin plus the value of the iron and lime contents being the credit, whereas the metal loss placed at the smelter's value for the metals, the charges for the silica and sulphur contents of the ore, the base cost of smelting, the cost of converting copper, and the interest charge for holding the metal stock, are the debits. The difference between debits and credits is the profit or loss. The refining company will conduct its accounts in a similar manner.

Résumé. It is evident from the foregoing that smelting rates and schedules are of a complex nature, although the principles on which they are based are reasonably simple. It is frequently stated that these rates and charges are made wilfully complex by the buyer, in order to obscure the amount of the deductions made. This view may have been correct in some instances, but the main reason for the complexity of present rates and schedules is to be found in the fact that the details have been increased from time to time as the smelting industry grew, new processes were invented, and new types of ores were found. It certainly seems desirable that the rates and schedules should be simplified in order that they may be more comprehensible to shippers of ores, particularly the small shipper who often is not familiar with the intricacies of the business and hence is not in a position to know whether justice is done him.

There is little question but that the principles upon which the rates and schedules are founded are just enough. However, individual deductions and charges for smelting might not be so reasonable. At first sight it would seem that when lead is worth 4.7c. per pound, a deduction of over 60% in this value to cover smelting, refining, and freight is too much. Determination cannot be made superficially, but there is no question but that, per ton of metal recovered, the smelting of low-grade lead or copper ore is much more costly than that of high-grade ore.

Another point of contention relates to the deduction for silica and the bonus for iron when ore is purchased on the neutral schedule. Frequently the penalty for excess silica is 12c. and the bonus for iron is 10c. It is claimed that the penalty and the bonus should equal each other. This claim is perhaps reasonable in copper smelting, in which the unit of silica is about equivalent to a unit of iron, but in lead smelting two units of iron plus lime are needed to be equivalent to one unit of silica, so that it seems fair to make the penalty on silica higher than the bonus for iron. However, in many contracts at the present time the bonus and penalty figures are equal. It is customary for a shipper who controls a considerable ore-supply to enter into contract with the smelting company for the treatment of his ores. In instances of this kind, which are frequent, much better rates and schedules are often obtained than are specified in the so-called open schedules, which are published for the shipper of small isolated lots. Rates also vary, the variation being dependent on the demand for certain kinds of ore. Thus, at times the silicious or 'dry' ores are scarce and again ferruginous ores are scarce, so that rates vary with the supply.

Oleic acid, usually called 'Red Oil,' is a fatty substance that plays the part of oil in the flotation processes. It is an organic acid obtained as a by-product in tallow-candle manufacture. It is solid at the ordinary temperature, and when required for flotation is liquefied by warmth, in order that it may be spread through the pulp, as butter is melted to a thin liquid in order to cover pop-corn.

Excavation continues at Panama, the June output of earth, rock, and gravel being 1,120,029 cubic yards.

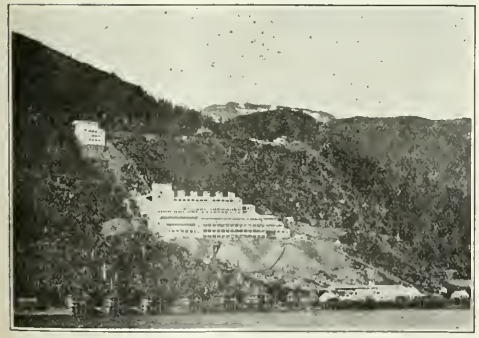
Perseverance Mine and Alaska Gastineau Mill

By ROBERT S. LEWIS

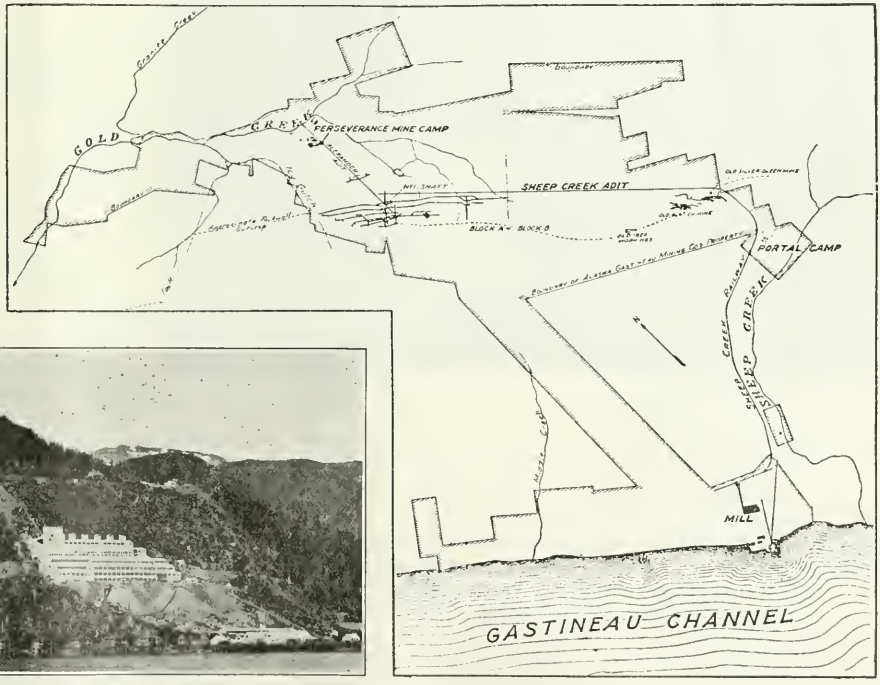
The mill of the Alaska Gastineau Mining Co. is at the town of Thane, 3½ miles down the Gastineau Channel from Juneau, where a large dock permits of landing supplies directly from steamships.

A railroad 17,000 ft. long connects the mill with the Perseverance mine. This road follows the northern side of Sheep creek for about 6000 ft. and then plunges into a 10,000-ft. tunnel that leads to the mine ore-bins in the very heart of the mountain. These bins are on the 1300-ft. level, the present bottom level of the mine, but prospecting has not yet been done to determine the lower limit of the ore, of which there is enough above this level to keep the mill running at full capacity for many years. The lode, which consists of slate, dips at approximately 70° and has a schist hanging wall and a greenstone footwall. Several gabbro dikes cut the lode. Stringers of quartz, varying in width from the thickness of a knife-blade to nearly two feet run irregularly through the lode and the dikes. The slate and gabbro carry small quantities of gold, but nearly all the free gold is found in the quartz stringers, together with pyrite, pyrrhotite, galena, and a little sphalerite. The stringers are richest in the gabbro, especially where sphalerite is present. Picked specimens show coarse specks of gold. Sorting cannot be done, consequently the entire lode is mined and sent to the mill. The lode varies in width from 50 to 200 ft., but the stringers of quartz often run out into the footwall, so that the limit of 'ore' must be determined by assay. A thin layer of slippery gouge keeps the lode quite free from the hanging wall. This fact is utilized in mining, as will be explained later.

A vertical shaft connects the 1300-ft. level with the top, or 500-ft. level, the shaft-house of reinforced concrete being built on the side of the mountain. This shaft is used only for hoisting men and supplies to the various levels. An air-driven hoisting-engine placed on the 1300-ft. level operates the two cages. The hoisting-ropes run up between the two compartments to the sheaves, which are set diagonally to the shaft in order to carry the ropes out to the centres of the compartments. Signals are given by the Anaconda system of flashing lights. In addition, a mine-telephone connects the levels with the out-



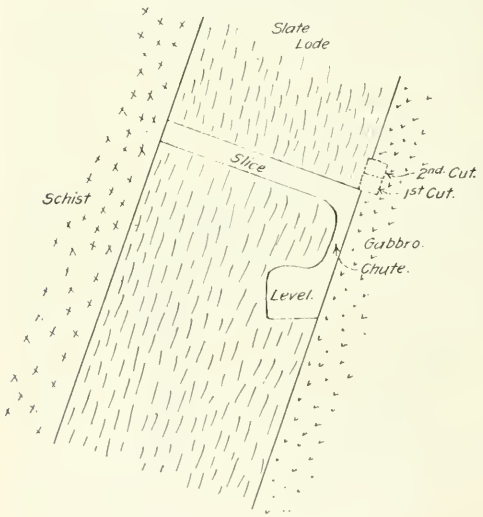
ALASKA GASTINEAU MILL, AT THANE.



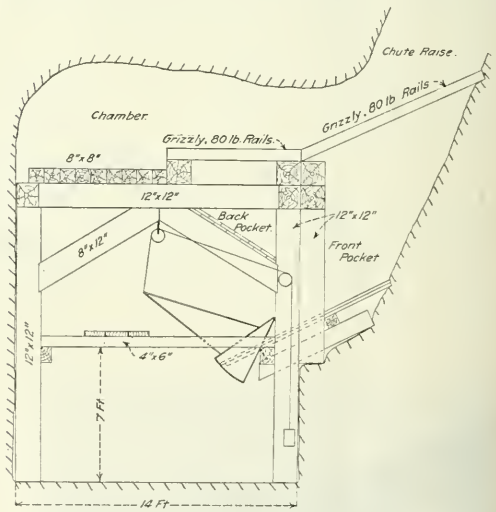
LOCALITY MAP OF ALASKA GASTINEAU PROPERTY.

side office. Since the engineer cannot see the shaft, a run-away and over-winding device has been found useful in preventing accidents. Several times, especially during the night-shift, it has kept the cages from being pulled into the sheaves.

From the different levels, which are 200 ft. apart, the ore is dropped through an ore-way to the 1300-ft., or main haulage, level. This ore-way is almost wholly in the foot-wall and parallels the vein. At the 900-ft. level a large timber bulkhead is used to break the fall of the ore that is dropped from the upper levels and thus prevent it from striking the bins at the bottom with destructive force. The bulkhead is hinged and is pulled out of the way when not required. In falling through the ore-way a marked sorting action takes place in the ore, so that when it is drawn from the bins the coarse pieces at the bottom come first and the fine comes last.



SKETCH OF CAVING METHOD.



BULLDOZING CHAMBER AND CHUTE.

Haulage to the mill is done by electric locomotives of the usual trolley type, but the interesting feature of the haulage in the levels is found in the use of storage-battery locomotives (6-ton Baldwin type.) Trains of nine 4-ton cars are hauled at any speed up to 16 miles per hour. An experience of over three years with this system of haulage has proved it most satisfactory. Costs are low, and the expensive and dangerous trolley-wire is eliminated. The locomotives are operated for 16 hours and are then charged for 8 hours.

In view of the large daily tonnage—over 12,000 tons—that is to be expected from this mine in the future, provision has been made for handling a much greater tonnage than is now being mined. (3300 tons per day was being mined at the time of my visit late in June.) The mine-cars are of the Granby type; this is an automatic side-dump car, operated by a projecting arm or lever which runs over a trip. After passing the trip, a car rights itself. The ore falls through a narrow opening into the ore-way. Thus the motor-man alone does both the dumping and the hauling. The cars pass over the dump at a speed of about three miles per hour. It is not likely that the haulage system will prove inadequate to any demands that may be made upon it.

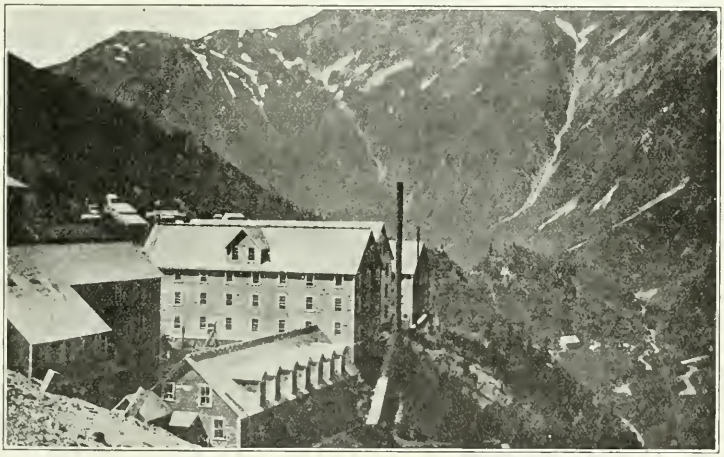
The stopes at full size are 400 ft. long with 40 ft. pillars between. A raise is carried through the middle of each pillar. Half of the raise is used as a man-way, the other half is a skip-way along which an air-hoist delivers drill-steel and other supplies from the level below. The stopes are started from the tops of chutes run along the foot-wall, although in wide stopes some chutes may be on the hanging-wall side of the vein. Two methods of stoping are used; shrinkage stoping and a special caving system. Shrinkage stoping is carried out in the gabbro, which is so hard that the back, far from requiring any support, must be drilled and blasted. The machines are set up on the broken ore, just enough of which is drawn out to afford working space for the miners. In the slate the caving system is best. This has been ascertained as the result of several years' experience with the vagaries of this particular material. From the tops of the chutes a slice is taken directly across the lode, and at right angles to the dip. (Though the lode is quite free from the hanging wall, it will not fall unless the cut should be made horizontally.) To start movement in the lode, a cut, well in the foot-wall, is next driven along the length of the stope. The cut is largely in the foot-wall to give the men a good roof under which to work. A slate roof is dangerous, it being almost impossible to test its firmness by sounding with a hammer or drill. Often no further work is necessary for some time, as the stope keeps slowly caving until a dome of equilibrium is established. Then a second cut will start the caving again.

One stope supplied ore for six months without a man working in it. In another stope four machines broke 26,000 tons in one month. In case the ore hangs or does not come down fast enough, a cut is made across the end of the stope along the side of the pillar. Faults in the lode cause no serious trouble from falls unless they are longitudinal faults, or faults of flat dip running along the length of the lode, when large blocks may come down. In one stope a block of ore 180 ft. long, 40 ft. wide, and 72 ft. thick came down in a solid mass. Nearly a month of drilling and blasting was required to get this ore into the chutes.

The prevent choking by large lumps, the chutes are protected by grizzlies, and safe places, called 'bulldozing chambers' are provided for breaking the large pieces. (See sketch.) The narrow neck protects the men working in the chamber from a dangerous rush of ore. All large pieces caught by the inclined grizzly are 'bulldozed' until they will pass through the horizontal grizzly into the back pocket below. This breaking of the ore before it reaches the chutes and oreways greatly lengthens the life of the ore-passes and makes it much easier to operate the bin-gates.

Water-Leyner piston machines are used for the heavy drilling in the stopes. Hammer-drills are employed in the raises, chutes, and for starting the stopes. Air is supplied at 100 lb. pressure. Dynamite of 30% is largely used, though 40% dynamite works to better advantage in the hard gabbro. In this gabbro 58 tons is broken per machine-shift as against 150 tons in medium-hard rock. The broken ore does not pack in the stope and runs freely whenever the gates are opened. Arc-gates are used throughout the mine. By the simple expedient of working from the bottom up, that is, the gates being pulled up to cut the stream of ore instead of being pushed down into it, they check the ore cleanly and almost instantly. The main loading-chutes on the 1300-ft. level have additional regulators in the form of the common rack-and-pinion gates. These are kept open at a suitable width, and serve to protect the arc-gates from the great weight of the ore in the bins. At this station four gates are used, one per car. In this way four 10-ton cars are loaded simultaneously, requiring only 8 spottings for the full train of 32 cars.

The very steep slope upon which the mill was built rendered it by no means an ideal millsite, a large amount of excavating in hard rock being required for the foundation. The bottom floor of the mill is 192 ft. above the Gastineau Channel, while the crushing plant is 493 ft. above the mill or 685 ft. above the water. Supplies are sent from the wharf directly to the mill over an inclined tramway, while a longer tramway carries material to a loading-station on the ore-railroad, from where it is sent either to the crushing plant or the mine. The rotary dump in the crushing plant handles four 10-ton cars at a time, dumping the ore upon an inclined grizzly having 8-in. openings. The grizzly is made of heavy I-beams, the upper flanges of which are protected from wear by manganese-steel shoes, which are cast in short sections to facilitate renewing. Air-operated finger-gates feed the oversize to two 36 by 42-in. Blake crushers set to 5 inches. From the crushers the ore passes over apron or caterpillar feeders, driven by changeable-speed gearing, to



THE MESS AND CLUB-HOUSE AT THE PERSEVERANCE MINE IN SILVER BOW BASIN, ALASKA.

stationary inclined screens made from ½-in. round iron and having 1½-in. square openings. The oversize, after being reduced in two No. 8 gyratories set to 2-in., unites with the undersize and drops into an ore-pocket directly beneath the crushing plant. This pocket is cut in solid rock and is 225 ft. in height, 110 ft. of which is the ore-pocket proper, being 30 by 50 ft. in cross-section. The remaining 115 ft. is a raise connecting the ore-pocket with the crushing plant. This unique ore-bin has a capacity of 10,000 tons. Arched steel plates between heavy I-beams form the bottom of the bin, and rest on reinforced concrete arches about 3 ft. thick. Between the arches are 8 variable-speed pulley-feeders, which supply ore to the 42-in. belt-conveyor. This conveyor, 608 ft. long, runs out through a tunnel to the coarse ore-bins in the mill. Operating at a speed of 315 ft. per minute, it has a capacity of from 300 to 600 tons per hour, depending upon the depth of loading. The entire framework of the conveyor is of steel, solidly anchored to the concrete floor of the tunnel. Ample space has been provided for a duplicate conveyor. From the bins the ore goes to stationary inclined screens having 1½-in. square open-

ings. The oversize is sent to 72 by 24-inch rolls set to $\frac{1}{8}$-inch and the undersize to 54 by 24-inch rolls set to $\frac{3}{8}$-inch. The rolls are run on choke-feed and crush dry. They are of unusually heavy design, having the large pulley in the form of a fly-wheel weighing 8000 lb. This construction requires an outboard bearing at the end of the roll-shaft. The bearings are water-cooled. Both large and small pulleys are on the same side of the rolls. The shells are 6-in. thick and are shrunk onto the roll-cores. Five-ton skips raise the product from the rolls 115 ft. to a series of 10-mesh impact-screens, the undersize going to the concentrating department and the oversize being returned to the 54-inch rolls. These skips represent a unique departure from the elevating machinery commonly employed in mills. Two work in balance, with automatic electric control. While it is being filled, the skip rests on a chair arranged to operate a trip when the desired weight of ore is in the skip. For smooth operation the hoisting cables must have any noticeable stretch taken up immediately, so as to maintain the skips in their proper relative positions. Each skip has an adjustable take-up for its cable. The flat cable, $\frac{5}{8}$ by $4\frac{1}{2}$-inch, is wound on a small reel, the shaft of which is the pin of the shackle connecting the cable to the skip. Stretch in the cable is taken up by a slight turning of the reel. Each of the four sections contains 15 impact screens, making a total of 60 for the mill, and there are two 54-inch rolls for every 12 impact-screens. The two 72-inch rolls serve the entire four sections of the mill. Seven sets of skips are used; one set for each 72-inch roll, and one set for each of the five pairs of 54-inch rolls. Dry crushing has the disadvantage of making the interior of the mill very dusty, but exhaust-fans are being installed. Judging from the performance of the first one, they should keep the mill fairly free from dust.

The concentrating department has a primary set of 10 double-deck Garfield tables and 10 Wilfley tables per section. Only two products are made; tailing and concentrate. The concentrate from the Garfield tables is treated on the Wilfleys, which make a concentrate that is shipped. This assays nearly 50% lead. The tailing from both classes of tables goes to a 4-spigot Janney classifier, the first three spigot-products of which are ground from 10 to 50 mesh in tube-mills running on open circuit. Each mill grinds 450 tons per day and is driven by a 50-hp. motor. A shovel-wheel dewaterer supplies the ore to the feed-box of the mill. The tube-mill product is treated on a secondary set of 10 double-deck Garfield tables, followed by 10 Wilfley tables, the wash-water for these tables being the fourth-spigot product of the classifier, together with the overflow from the tube-mill feed-dewatering wheel. Each primary Garfield table handles 300 tons per day or 150 tons per deck. A 15-hp. motor drives the 10 tables. A very simple method is used to carry the feed to the lower deck of these tables. The feed-box for the upper deck has five 2-in. pipes, set vertically and running entirely through it. Pulp to the table is supplied from a stationary feed-box with five spigots, having the same spacing as the pipes in the bottom. While the table is running, the pipes are beneath the spigots half of the time, thereby sending the feed to the lower deck. The concentrate from the secondary Wilfley tables will receive a more extended treatment than it does at present, when the new concentrate re-treatment plant is running. Now four different grades of concentrate are sacked and shipped to the smelter. It is stated that the mill heading averages $1.68 per ton and the recovery is 87%. The total operating cost is given as 64c. per ton. The visitor to this property cannot but be impressed with the magnitude of its operation and with the efficiency of the staff, which has brought a difficult problem to such a successful issue.

This application of copper concentration methods to a gold ore is startling at first glance. But with an ore that cannot profitably be cyanided and that is of such low grade that an enormous daily tonnage must be milled to make the small per-ton profit of economic importance, the innovation has been amply justified.

Filing systems for papers are numerous but two only are worth considering. The Dewey system of decimal classification is used by the United States department in Washington. By this system all knowledge is divided into ten classes and these again subdivided decimally. As applied to a telephone company the divisions are: 000 General, 100 Executive, 200 Finance and Accounts, 300 Construction, 400 Equipment, 500 Operation, 600 Rates. Each of these classes may be subdivided. For example, the heading '300 Construction' is subdivided: 310 Real Estate, 320 Pole Lines, 330 Circuits, Loops, etc.; 310 Real Estate is subdivided thus: 310.0 Purchase of property, 310.2 Construction of new buildings; this heading can be again divided 310.21 Plans and Specifications, 310.22 Contracts for new buildings, 310.23 Interior appointments; this last could be subdivided 310.231 Lighting, and this again into 310.231.1 Electric wiring, and so on to any degree of minuteness. A cataloguer familiar with the system would know that 016.581.974.-742 meant 'Bibliography of the Flora of Albany County, N. Y.' But to the ordinary persons the numbers convey no information, though they tell a definite story to the expert.

Diamonds were first found in New South Wales by E. J. Hargraves, the discoverer of gold, in 1851. The largest diamond yet found is said to have been obtained at Mt. Werong, near Oberon, in 1905, and weighed 28.5 carats. It is difficult to secure accurate statistics of the production of precious stones, but the yield of diamonds in 1912 was estimated at 2240 carats, valued at $10,000. The total production to the end of 1912 is given as 178,971 carats, valued at $600,000.

Graphite production of the United States in 1914 was 4336 tons, worth $324,118. Most of the crystalline, and all of the flake variety, was extracted in New York, Pennsylvania, and Oklahoma. The International Acheson Graphite Co. of Niagara Falls, manufactured 10,455,139 lb. worth $698,800.

Pre-Cambrian Ore Deposits in Ontario

By WILLET G. MILLER and CYRIL W. KNIGHT

*Introductory. During the last decade, owing to the great progress that has been made in the production of metals in Ontario, special facilities have been provided for the study of pre-Cambrian rocks. Our information has been much increased concerning the age relations of the rocks that represent various epochs of this great period, and the ore deposits that are associated with them. It has seemed to the authors that it might now be of interest to present a classification of the pre-Cambrian ore deposits of the Province, showing the various metallogenetic epochs into which the period may be divided. In no other part of the continent or the world has the pre-Cambrian proved to be of greater economic interest. The Province has not only the world's greatest deposits of nickel, among which have been developed mines that compare favorably in economic importance with those of any other metals found elsewhere, but the gold mines and the cobalt-silver areas are recognized as being among the greatest known.

From the following table it will be seen that there have been at least four great metallogenetic epochs during the pre-Cambrian period in Ontario, namely, Grenville, Algoman, Animikean, and Keweenawan. A fifth epoch of importance should probably be added to represent the orebodies associated with the basic intrusives that preceded the intrusion of the Algoman granite and followed the deposition of the Timiskamian sediments. There is proof that many important ore deposits have been removed by erosion, and it seems not unlikely that the rocks of certain epochs, not now productive, contained deposits that have disappeared through the removal of vast thicknesses of material.

GEOLOGIC MAP OF ONTARIO.

Economic Importance of Various Epochs. The table gives the value of the metallic production of Ontario for the year 1913, classified according to age and origin. Considerable nickel, cobalt, and arsenic in the Cobalt ores are not represented in the table, nothing being received for them by the mines. A comparatively small quantity of the nickel and copper should be credited to the deposit in Dundonald township, which is associated with the basic eruptives of pre-Algoman and probably post-Timiskamian age.

It should be understood that the ages given for the deposits do not refer to secondary concentration, as, for instance, in the case of iron ores, but to the epoch in which the metals were first deposited.

While at present there is no production of iron ore from deposits of Animikean or Timiskamian age in Ontario, millions of tons are mined from deposits of these epochs in the state of Michigan.

Since the authors have given elsewhere an explanation of the nomenclature employed in the table, it is not necessary to deal in this paper with the names applied to the various subdivisions of the pre-Cambrian.†

Certain metals may occur in economic quantities in more epochs than the table shows that they do, the authors not having been able to determine definitely the age relations of some deposits.

Sequence of Intrusion and Metal Deposition. The table brings out an interesting alternation of igneous intrusion and sedimentation, and the importance of the igneous rocks in the formation of ore deposits. It will

*Abstract of paper entitled 'Metallogenetic Epochs in the Pre-Cambaian of Ontario,' presented before the Royal Society of Canada, Section IV, May 1915, and prepared by the authors.

†Ontario Bureau of Mines, Vol. XXII, Part 2, pp. 123 *et seq.*, and Geol. Soc. Am., 1914, abstract.

be seen that there are broadly five great epochs of intrusion, basic and acid rocks alternating, namely, (1) Keewatin, basic; (2) Laurentian, acidic; (3) pre-Algoman, basic; (4) Algoman, acidic; (5) Keweenawan, basic, passing in places into a considerable volume of acidic varieties. The pre-Algoman basic rocks are of greater volume and wider extent than they are usually recognized to be, since they are frequently wrongly classed as Keewatin. These basic rocks are represented by the sudburite of the Sudbury area, by the lamprophyres of Cobalt and elsewhere, and apparently by the basic rocks of the townships of Dundonald, Reaume, and others where associated with them are nickeliferous pyrrhotite and chromite.

Owing to erosion, the sequence of metal deposition shown in the table is doubtless incomplete. Iron 'formation' occurs in three epochs, the Grenville-Keewatin, Animikean, and Timiskamian, but is of economic importance only in the former two. Certain deposits of titaniferous and non-titaniferous magnetites, not now being worked, are associated with basic intrusives that appear to be of pre-Algoman age. Arsenic occurs in two epochs and has been produced in economic quantities from rocks of both. In so far as is shown, gold occurs in economic quantity only in the Algoman, although small quantities are obtained in refining the copper-nickel ores, and certain auriferous quartz deposits, not now productive, appear to be genetically connected with Keweenawan intrusives. Nickel, as has been shown in a preceding paragraph, was deposited in economic quantities in two epochs. Cobalt, silver, and copper are produced only from deposits of Keweenawan age. Platinum, palladium, mercury, and other metals are found in small quantities with Keweenawan ores. Zinc and lead have been mined in the Province, but the age relations of some of the deposits are in doubt.

Keweenawan. The basic rocks that are classed as of Keweenawan age are found in numerous localities as dikes, sills, and flows over a vast region in that part of the protaxis occupied by Ontario, Michigan, and adjoining territory; in so far as can be determined at present these rocks are also found far to the northeast in the former territory of Ungava, now part of Quebec, and to the far northwest in the Coppermine River basin and northward to the Arctic coast.

In Michigan and in the Coppermine River country these basic intrusives are considered to be genetically connected with deposits of native copper. In Ontario, along the north shore of Lake Huron, the Keweenawan intrusives appear to have given rise to the deposits of copper pyrite, while at Sudbury the copper-nickel ores and at Cobalt the silver-cobalt veins have been shown to be genetically connected with them.

While it is not the intention in this paper to go into detailed descriptions, there are a few facts relating to the ores that are genetically connected with the Keweenawan basic intrusives that should be emphasized: (1) They contain the greatest known quantities of the two magnetic metals cobalt and nickel and a high percentage of the third element, iron. (2) The deposits are widespread. In the region surrounding Cobalt, silver-cobalt veins are found here and there over an area at least 5000 square miles in extent. Beyond this region cobalt ores are associated with these rocks in the township of Otter, north of Lake Huron, and in small quantities along the shore of the lake opposite Desbarats. Similar ores have been found in Michipicoten island in Lake Superior and in the area tributary to Port Arthur, 500 miles distant from Cobalt. With the effusive rocks of Michipicoten island is also found native copper under conditions similar to those of Michigan and the Coppermine River region. (3) Some of these ores, those of Sudbury, are considered to be a direct segregation from the magma, while the cobalt-silver deposits are less direct, having been deposited from aqueous solutions, although a few veins partake to some extent of the character of deposits formed by segregation from a molten magma.

Animikean. Interbedded with the Animikean clastic sediments are vast quantities of iron formation, a chemical deposit. Through the action of aqueous solutions, concentration of the iron has taken place, giving rise to orebodies of economic importance.

While the iron deposits of Ontario in the Animikie series of the north shore of Lake Superior have not proved to be of much economic value, across the international boundary in Minnesota they are represented by the great Mesabi orebodies.

Algoman. Gold deposits, which are found in numerous localities in the Province, from the Quebec boundary on the east to that of Manitoba on the west, are, in many cases at least, genetically connected with granites to which the name Algoman is applied. In a few cases the granites are represented by more basic rocks. The gold occurs in quartz veins, being associated usually with iron pyrite, but occasionally the ore carries considerable arsenical pyrite, or mispickel. Some of these veins have been worked as a source of arsenic. There are thus two epochs in which arsenic has been deposited in economic quantities: the Algoman and the Keweenawan, represented by the cobalt-silver arsenical ores of Cobalt.

The gold deposits are found chiefly in Keewatin schist, but a few occur in Timiskamian clastic rocks. It is worthy of note that the only gold deposits of the Province that have been proved to be of great economic importance are found in, or in the vicinity of, these Timiskamian fragmental rocks.

Most of the gold in the important deposits, belongs to a time later than the mass of the veins, having been deposited after the veins were disturbed and fractured.

Basic intrusives that appear immediately to precede the Algoman granite are genetically connected with important nickeliferous pyrrhotite deposits in the township of Dundonald and with small deposits of chromite and pyrrhotite, which have not proved to be of economic value, in the township of Reaume. These intrusives have not been proved definitely to be later in age than the Timiskamian sediments, but they appear to be so. If

this is their age, they correspond chronologically with the lamprophyre dikes of Cobalt and elsewhere and with the sudburite of Sudbury. Basic rocks genetically connected with titaniferous and certain non-titaniferous magnetites appear to be of the same age.

As in the case of arsenic, there are thus two epochs of nickel deposition in Ontario, the Keweenawan and that described in the preceding paragraph.

Basic rocks contemporaneous with sudburite are more widespread in the Province than is generally recognized, for they have frequently been classed as of Keewatin age. No age name has been applied to these rocks.

Grenville and Keewatin. Iron formation representing chiefly chemical deposits laid down during Keewatin-Grenville times is widely distributed. In fact, it may be said that there is scarcely a locality in the Province where Keewatin rocks are found that iron formation is absent. The iron formation usually consists of interbanded silica and iron ore, magnetite or hematite, but in places there is considerable siderite, or iron carbonate. Through the action of aqueous solutions on the iron formation workable deposits of ore have been produced at various localities.

Erosion of Ore Deposits. Nearly all the ore deposits

Pre-Cambrian Epochs of Ontario and Their Metal Production	Production in 1913	
Keweenawan		
Epoch, following basic intrusions, of (a) silver, cobalt, nickel, and arsenic at Cobalt and elsewhere, (b) nickel and copper at Sudbury, and copper elsewhere. Some gold deposits, not now productive, appear to belong to this epoch.	Silver	$16,987,377
	Copper	3,952,522
	Nickel	14,903,032
	Cobalt	525,028
	Cobalt and nickel	90,266
	Arsenic	101,463
		$36,559,688
Animikean		
Epoch of deposition of 'iron formation' as a chemical precipitate.	Iron ore	Nil
(Algoman)		
Epoch, following granite intrusions, of gold at Porcupine and at many other localities, and of auriferous mispickel. Deposits of galena, zinc-blende, fluorite, and other minerals also appear to have been derived from granite, but some of them were not formed till post pre-Cambrian times. Preceding the intrusion of the Algoman granites, basic intrusives, that appear to be of post-Timiskamian age, gave rise to nickel and titaniferous and non-titaniferous magnetite deposits and chromite.	Gold	$4,543,690
Timiskamian		
Epoch of minor deposition of 'iron formation' as a chemical precipitate.	Iron ore	Nil
(Laurentian)		
Granite intrusions probably gave rise to ore deposits that have been removed by excessive erosion as is known to be the case with deposits of later origin.		Nil
Loganian		
Grenville and Keewatin	Iron ore	$ 237,976
Epoch of deposition of extensive 'iron formation' as a chemical precipitate among other sediments.	Iron, pig	975,174
		$1,195,150

Timiskamian. No ore deposits are known to have been formed during Timiskamian times in Ontario. It may be added that on the United States side of Lake Superior rocks that appear to be of Timiskamian age contain extensive deposits of iron formation, with which are associated orebodies of commercial importance.

Erosion has removed by far the greater part of the Timiskamian rocks that once were widespread in Ontario, and it is possible that ore deposits of this epoch have also been destroyed.

Laurentian. No orebodies that are genetically connected with Laurentian granite and gneiss are known to occur in the Province, but as rocks of this epoch that are now exposed at the surface represent originally deep-seated material, from above which thousands of feet have been eroded, it is impossible to say that orebodies of Laurentian age have not been destroyed.

of the Province have been subjected to excessive erosion. The few exceptions that are known are represented by so-called 'blind' veins or those that do not come to the present surface, such as a small number of silver veins at Cobalt.

While it is not possible to determine the total amount of erosion to which the pre-Cambrian surface has been subjected during various epochs, since the Keewatin-Grenville rocks appeared above the surface of the primeval ocean, it can be proved to be enormous.

In pre-Timiskamian times the Keewatin-Grenville rocks were eroded to a great depth, as is shown by the thickness of the Timiskamian sediments, and the deep-seated Laurentian was exposed at the surface.

Again, in the epoch that gave rise to the Animikean sediments, erosion of all the older series was excessive and long continued. The folded Timiskamian frag-

mental rocks were cut down until they were represented merely by comparatively narrow belts in some localities, while over large areas no remnant of them remained. During this epoch the Keewatin, Grenville, and Laurentian again were subjected to great erosion.

In post-Animikean and pre-Paleozoic times there was a great erosion epoch. This is shown by the outlier of the Cobalt series, and the intrusives that penetrated it.

Since Paleozoic times there has been again much erosion, so that the Cambrian, Silurian, and Devonian strata have been removed over vast areas, exposing the underlying pre-Cambrian.

That many ore deposits of various ages have been destroyed during the several epochs of erosion is evident. Two or three hundred feet more of erosion would have left comparatively little, for example, of the Cobalt silver deposits, of which doubtless more has been eroded than has been mined, or of the great Mesabi iron deposits of Minnesota.

In considering the relation of ore deposits to erosion in the pre-Cambrian of Ontario it appears that workable ore deposits are confined to near the surface.

Complete erosion of certain series of rocks, it would seem, may account for the absence of ore deposits in those countries where the pre-Cambrian, although occurring in considerable volume, is barren. For instance, in the northwest highlands of Scotland there is evidence that fragmental series, probably corresponding to the Timiskamian and Animikean of Ontario, were completely eroded before the deposition of the Torridonian, which is considered to represent the Ontario Keweenawan. If we except the Moine or Eastern schists, the age relations of which are doubtful, the rocks now remaining in the Scottish pre-Cambrian appear to represent the Keewatin and Grenville, with the deeply eroded roots of intrusives, and the Keweenawan. If all the sedimentary series that lie between Keewatin-Grenville and the Keweenawan had been removed by erosion in Ontario, there would be nothing left of the orebodies that are now found enclosed in Timiskamian and Animikean rocks or in the intrusives associated with them, and the deposits of whatever age enclosed in the Keewatin and Grenville would also have largely disappeared.

Faulting and folding have preserved parts of orebodies that otherwise would have been completely destroyed by erosion. This is well illustrated by the Cobalt Lake fault, where silver veins have been protected on the down-throw side of the fault. Had it not been for this fault, and others associated with it, practically all the ore that has been mined in the vicinity of the fault and to the west of it would have been removed. Folding at Kirkland Lake and Porcupine has preserved comparatively narrow synclinal belts of Timiskamian sediments and the weathered Keewatin rocks that immediately underlie them, and at one time formed the surface of the earth. There is no reason for believing that erosion has been less in the two localities mentioned than elsewhere in the pre-Cambrian, but probably the character of the rocks, all of which were at one time, before folding took place, subjected to surface influences, has a bearing on the formation of openings and the deposition of ores. The gold deposits are found both in the Timiskamian sediments and in the Keewatin, the more schistose and more highly altered varieties of the latter group appearing to be the greater economic importance.

The French Zinc Process

This process consists in dissolving the zinc from a roasted ore by means of bisulphate of soda, to which a little manganese (oxide?) has been added, according to an anonymous writer in the *Nelson Daily News*. The zinc is then precipitated electrolytically.

The process is now being worked by the Standard Silver-Lead Mining Co. at Silverton, Slocan lake; the plant contains two completely equipped dissolving vats each capable of dealing with a charge of 2500 lb. of liquor and about 1000 lb. of ore. The zinc-depleted liquor containing bisulphate of soda from the electrolytic vat is pumped into the upper of these two vats. There is then added 700 to 1000 lb. of roasted ore from which the zinc has been partly extracted in a previous operation. In about an hour the solution of the zinc is finished and when the liquor has settled for a short time it is allowed to run down into the second dissolver, placed at a lower level. The sludge remaining in the bottom of the dissolver is then pumped through a filter-press to remove the water and the residue contains all the silver and lead. As the sulphur to the extent of more than 20% has been driven off in the roasting operation and zinc to the amount of about 40% has been extracted, the residue of the ore, of which a large quantity was treated, only weighed about 45% of the original ore. As it contained all the silver and lead originally in the roasted ore, the proportion of these metals was more than doubled. For instance, the ore treated had 31% zinc, 3.5% lead, and 32 oz. silver per ton. The zinc depleted residue contained 76 oz. silver per ton, and 8.7% lead, and 92% of the zinc had been taken out, that is, 2.7% of the zinc counted on the original ore was left in the residue. This residue is now ready for smelting or other treatment for the recovery of its lead and silver in the usual way. To the liquor that has been run down into the second dissolver, a quantity of roasted ore is again added to neutralize the bisulphate of soda. As soon as this has taken place the liquid settles rapidly to a clear solution, which is pumped through a clarifying filter-press, and is then ready to have its zinc deposited in the electrolytic-vats. At the Standard Co.'s plant only one electrolytic-vat was used, as the dynamo-power at disposal there was limited. Nine anodes were used and eight cathodes of the largest size each with an area of 8 sq. ft. What can be done with one vat can be done with any number on a large scale, a reduplication of vats of the same size being all that is necessary. The plant was well designed and erected and the results of running a large quantity of ore gave a remarkably good current consumption.

PALACE OF MINES AND METALLURGY.

Mining and Metallurgy at the Exposition

Engineers attending the meeting of the International Engineering Congress at San Francisco, during the period September 16 to 25, will find much of interest in the Palace of Mines and Metallurgy at the Panama-Pacific International Exposition. Some may be disappointed; others may consider it worthy of a great industry; we leave judgment to the visitors. If the original plans had been carried out, the place would be a hive of industry; however, things must be accepted as they are. Mine equipment is not complete without power, so engineers must step across the Avenue of Progress to the Palace of Machinery to see some of the latest prime-movers. The centre of attraction in the mining department is 'The Mine,' and as sections of some of the greatest mines in the country are represented, this should be the starting point for further exploration of the exhibits. This excellent model mine was constructed under the supervision of the U. S. Bureau of Mines, in co-operation with the mining companies represented.* The underground workings may be entered by an electrically-operated hoist, or by walking down the incline or slope. Mining men will feel at home as soon as they enter on account of the characteristic odors of decaying timbers and wet rock found in real mines. The excavation is below sea-level, but continuous pumping saves it from being flooded. In the small space occupied by the mine, the zealous student can learn more of underground mining from the exhibits and the courteous explanations of the white-capped young engineers than he could by months of hard study under the ablest of professors. Here are illustrated most of the methods and machinery used in coal and metal mines.

As you descend the well-worn steps of the incline, you need light to illuminate the darkness, and there is a choice of electric, oil, or acetylene safety-lamps, or an ordinary lamp. Should you need to resuscitate an asphyxiated person, the lungomotor is at your service. At your left, as you advance, is a Hercules powder-magazine with enough alleged dynamite to blow the whole building through the Golden Gate. The powder-magazine is not properly situated; in an actual mine it would not be in a cross-cut opening directly into a main gallery, but would be around at least two corners, so that the force of a possible explosion would expend itself on the rock-faces, and not on the unfortunate miners.

A little beyond the powder-magazine the first real mining appears. This consists of a completely timbered stope from the Goldfield Consolidated mine, in Nevada. Ore lies on the floor as if just broken. A small drill is ready to commence on a raise.

Next comes a model of the system of mining in vogue at the renowned Homestake, in South Dakota, one of the world's greatest gold mines. It has paid $35,000,000 in dividends, and yet there is 30 years' ore developed. At present the mills are crushing 4500 tons of $4 ore daily. This carefully made model, if correctly understood, conveys as much information as a good-sized volume on mining methods. It illustrates the working of a wide vein of low-grade ore by shrinkage-stoping. By a complexity of drifts and cross-cuts the 500-ft. wide zone of schist and quartz is divided into blocks 500 ft. wide, 60 ft. long, and 150 ft. high. This block is shot down in pieces up to 50 tons in weight for a height of 115 ft., and allowed to remain where it falls, without the use of

*See also 'The Mine—An Educational Exhibit,' by the Editor, M. & S. P., May 1, 1915.

timber. The 35 ft. separating this stope from the ground above is worked by means of square-sets, and then the whole stope is filled with waste. A mat of heavy timbers supports this waste and allows it to settle gradually. This is an admirable model and should be secured by one of our universities. Sample of ore and rock from the Homestake are also on view.

One would think that the Bunker Hill & Sullivan company had bodily transferred one of its stopes from Idaho to the Exposition. The placing of this lead-silver ore (8% lead and 8 oz. silver) took a mining engineer and his assistant two months; the total expense of this small exhibit was $5000. This reproduction of an actual working-face is excellent. The facility for artificially constructing an orebody has often been used for fraudulent purposes in various parts of the world. In one case an expert found that the mine had been gutted behind an artificial wall a few feet thick; in another the perpetrators of the fraud were victims of their own lack of faith, as the would-be victims eventually found rich ore. This was in a noted silver-lead mine in Nevada, some 50 years ago. The Bunker Hill exhibit shows an ordinary waste-filled stope, a much commoner system than that of the Homestake. Among the photographs on the wall, those that show the wreck of the Wardner mill after it was dynamited on April 29, 1899, by a thousand or more miners who came on a captured railway train, and the photograph of the ill-famed 'bull-pen' in which several hundred miners were subsequently imprisoned, should be of special interest to students of our industrial history. A Baldwin-Westinghouse storage-battery (Edison) locomotive, hauling two 25-ton cars of ore just filled from a chute, is ready to pass out of the level. On the lower levels storage-batteries are used; trolleys appear in the main adit.

Copper men have their turn next at the Copper Queen mine, Arizona. There a stope, ore-chute, man-way, timber-way, and timbering are shown; also faces of ore in place, slabs weighing a ton or more each being brought from Arizona. Specimens are exhibited of tenorite and melaconite in kaolin, chalcocite and pyrite, chalcopyrite and bornite, cuprite and malachite in iron oxide and kaolin. This exhibit cost $10,000.

Iron mining is shown by workings of the Lincoln mine at the great Mesabi range, Minnesota.

The black coal mines seem gloomy when contrasted with the bright ores of the Copper Queen. Reproductions of the anthracite mines of Pennsylvania and the bituminous mines of Kentucky, West Virginia, Wyoming, and Washington contain various coal-cutting machines, electric locomotives, drills, cars, safety-exit, manway, automatic mine-door, and other appliances used in such mines.

Between the metal and coal displays is a station where a motor-driven compressor supplies air for the drills, a centrifugal pump for draining the mine, a winze with sinking-pump and small hoist, and a Waugh drill, which occasionally bores a hole in a block of concrete. Fresh air from the surface is introduced at this station by a Sirocco fan working near the collar of the main shaft. A fuse magazine, a cap and fuse exhibit of the Ensign-Bickford Co., underground foreman's office, and a motion-picture theatre where actual mining scenes are shown, complete the workings.

The fact that the Bureau of Mines has reduced the cost of producing radium to $36,050 per grain of bromide will perhaps make a visit to the radium booths more interesting.

At 2 p.m. each day, save Sunday, the mine crew of the Bureau gives an exhibition of rescue-work and first-aid. A violent explosion occurs; protected by their Draeger helmets and store of oxygen, the rescuers enter a room full of poisonous gases, rescue a supposed victim of the explosion, resuscitate him by the most approved methods, and finally leave him in charge of a surgeon and nurses in the complete hospital near at hand. The Proto and Westphalia rescue apparatus are also ready for emergency.

The Bureau's exhibits on the main floor of the building include lantern-slide pictures, a gas-proof smoke-room to test rescue-appliances, a collection of ingredients used in the manufacture of explosives, and samples of the final product, welfare demonstration, a map showing the position of the Bureau's rescue-cars and stations in the East, apparatus to minimize the explosibility of coal-dust, operating devices showing the losses that occur in burning coal in various types of boiler-furnaces, and many other instructive arrangements, including photographs of mining and metallurgical activity.

With the co-operation of the American Smelting & Refining Co., the Anaconda Copper Mining Co., Phelps, Dodge & Co., the International Nickel Co., the Thiogen Co., the Braun Corporation, and the Nevada Mine Owners' Association, the U. S. Bureau of Mines has fitted up a complete testing laboratory. Smelter-fume investigation and cyanide problems are the principal subjects at present. In the former, the solid particles have been studied, while the gases are yet to be investigated. The apparatus includes Braun laboratory appliances, a model bag-house given by the Mammoth Copper Co.; from the Western Precipitation Co. came a model of an installation at the Trail smelter, in British Columbia, and a working unit capable of dealing with 500 cu. ft. of gas per minute; a Wedge multiple-hearth roasting-furnace; a Dwight-Lloyd sintering-machine and product; and a complete assaying and chemical laboratory. For instruction of visitors various mill and refinery products from the Homestake mine, plans of smelters, and assaying are described graphically.

Adjoining the Bureau laboratory is a cyanide-plant, which can be operated to suit any tests being made by the Bureau staff. The visitor can see the operation of an 18-in. by 4 ft. 6-in. Hardinge, motor-driven, herring-bone-gear, conical pebble-mill in closed circuit with a simplex Dorr classifier. The Dorr company also has three 6 by 8-ft. tanks, serving as thickener, agitator, and thickener respectively. Less than 1 hp. drives the gear. Slime from this plant can be pumped to the Merrill

Metallurgical Co.'s installation of an automatically-sluiced slime-press of 30-ton capacity per day, a new type of solution clarifier, precipitation-press, and zinc-dust feeder. Byron Jackson stage-pumps move the solutions and pulp. Adjoining this plant, but not connected with it, is a complete Oliver continuous filter, treating heavy flotation concentrate from the Anaconda company's Washoe plant.

In its endeavors to instruct the engineer and layman, the U. S. Geological Survey has an extensive exhibit near the Bureau of Mines. This includes examples of the work done by the various departments of the Survey, and pictures of field-work, indicating how, where, and why it was done. Cases contain maps of the coal-fields of the United States, samples of coal, and details of age, number, and thickness of beds. Other cases contain samples of minerals and products reduced from them, and brief descriptions of their use. After seeing these the visitor can wander among maps, field-instruments, stream-flow instruments, drafting materials and instruments, and models showing the activities of the Survey.

"Alaskans please register" is the sign in front of the Alaskan exhibit, adjoining that of the Survey. A golden cube, about 9 ft., represents the Territory's gold output from 1880 to 1914 inclusive, a total of $244,156,799. Samples of gold, silver-lead, and copper ores, and coal are shown in several cases. Mention of copper is interesting, as this year it is expected that the Kennecott company's mines will produce 70,000,000 lb., a figure close to some of the greatest copper mines in the United States. A section of a Sitka spruce, 7 ft. diameter, gives an idea of the growth of timber; so also the furs, grasses, grain, fruit, vegetables, and the skin of an 11-ft. bear illustrate other resources of the territory.

Millmen should not miss an inspection of the Pacific Tank & Pipe Co.'s manufactures, the Senn concentrating-tables, the Trent cyaniding apparatus, and the Straub circular 10-stamp mill.

Only the States of California, Idaho, Missouri, Nevada, New York, and Oregon have made a mining and metallurgical display. The Anaconda exhibit may be said to represent the greatest centre of activity in Montana. Alaska has been described above. Principal features of each are as follows:

California. Cases containing ores and minerals from several counties, placer gold, a model of the Mammoth copper mine, metals, photographs of mining scenes, a model hydraulic mine in operation, a Hendy full-size giant, a model electrically-driven Yuba Construction Co.'s dredge, and a peg-model of the Sunset-Midway oilfield. Geologists should not fail to examine the last.

Idaho. An area of 49 by 61 ft. contains 250 samples (one piece weighs 3860 lb.) of gold, silver, lead, copper, zinc, and rarer ores. The well known Sawtooth mountains form a background. Mill-products and photographs explain the activities in many directions.

Missouri. Zinc and lead naturally occupy large space in this booth. These products of the State are valued at about $30,000,000 per year. The famous Joplin zinc district is thoroughly explained by a mine-model, drill-cores, ores, a complete operating 25-ton mill, and zinc manufactures. The lead area displays ores, four tons of pig-lead, and sublimed lead products.

Nevada. The excellence of this exhibit is shown by the prizes given to it by the Exposition Jury of Awards. Nevada is essentially a mining region, a normal year's metal output being nearly $40,000,000. Some famous gold, silver, and copper mines are situated within the State. The display is instructive in its relief map, cases of rock and ore, mine-models, geological maps, flow-sheets of mills, panorama of mining districts, and cubes representing outputs of the various metals. Specially interesting are the platinum ores from the Boss mine.

New York. The booth of this State is likely to be overlooked, as many people do not know that the annual output of minerals is over $40,000,000. Indeed, it is an interesting display, largely from a metallurgical point of view. Lime, cement, talc, magnetite iron ores, pyrite, oil, garnet, carborundum products made at Niagara Falls by the Acheson process, graphite ore and graphite products from the Joseph Dixon Crucible Co.'s mines and mills, a model of the Sterling salt mine at Halite, with the grades of rock-salt made, an instructive diagram of the Solvay ammonia-soda process at Syracuse, and other things make the whole worth a visit.

Oregon. Considering the relatively small production of gold, silver, and copper in this State, the display is creditable. Dredging men will be interested in the coarse, flaky gold recovered by the only boat, the Powder River dredge at Sumpter. Gold-silver ores from mines in Baker, Grant, Josephine, and Malheur counties show the varied character of the district. Useful building-stones are on view.

Montana. Copper men would expect a good exhibit by the Anaconda company of Montana; in this they will not be disappointed. The floor-space is 3500 sq. ft. The exhibit has been arranged to take the visitor step by step through the various processes that the ore undergoes from the time it is taken from the mine until the finished wire-bar, cake, or ingot copper is shipped to the consumer. The geology of the Butte district is shown by plans and models of mines. Large specimens of ores show the association of minerals. More models illustrate mining methods, timbering, and head-frames. Wet concentration, smelting, and their products are explained by display-bottles and a complete collection of common shapes of refined copper.

Lead miners and millmen will be particularly interested in seeing their metal reduced to a product that consumes a great deal of the lead output, namely, white lead. A complete plant, using the Dutch process, is in operation, the exhibit of the W. P. Fuller Co., San Francisco. Behind it is a multi-colored Moorish pavilion, showing artistic taste in construction and in the use of paint.

For the reduction of tin concentrate from Bolivia, a smelter is now being erected in the East, so the extensive

display of tin ores from that country may be studied with profit.

The Argentine Republic is not generally connected with much mining, but the large and well arranged lot of samples of ores, rocks, oils, etc., will surprise even those well informed concerning South American resources.

As in many other departments of the Exposition, Japan is prominent in the Mines building with an excellent assortment and display of coal, ores, and metals from a number of important mines. The Japanese government co-operated with the large mining companies, including the Mitsu Bishi & Co., Mitsu Mining Co., Kuhara Mining Co., Imperial Steel Works, Hokkaido Colliery & Steamship Co., Nippon Oil Co., and the Japan Sulphur Co. The Imperial Geological Survey's collection includes minerals and fossils of the islands, supplemented by the economic minerals.

Chemists will find the Stauffer Chemical Co.'s exhibit of various acids, alkalis, and paints of interest.

A golden obelisk and two golden spheres are prominent objects in the centre of the building. They represent the gold output of the Witwatersrand compared with other countries and the rest of the world, respectively. In 1914 the Rand contributed 38.3% of the world's total of $446,500,000. A model of the surface equipment of the Modder B mine shows the typical Rand arrangement of plant. The peculiar 'banket' ore from the 'reefs' will attract attention, so will the many photographs of the principal properties.

The oil production of California was approximately 100,000,000 bbl. last year, valued at $50,000,000, or 50% of the total mineral output. It is therefore fitting that a good deal of space is devoted to various phases of oil production. The models of the Lakeview oilfield, Section 36 of the Midway field, and the Richmond refinery, all shown by the Standard Oil Co. of California, are full of interest. So is the large map of the United States on which are marked oilfields and pipe-lines. Few people realize that a continuous pipe-line connects New York and the Gulf of Mexico—near Beaumont—a distance of about 2500 miles. An important device invented by the Standard's engineers is that for excluding water from oil-wells. This is of the utmost importance to oil-producers, millions of dollars having been wasted for want of a similar system in districts that have been ruined by the influx of water into the wells. A collection of fossils, some under small microscopes, characterizing the oil formations, is shown. Road-building materials are explained by those in charge of the exhibits. The section of 10-in. pipe, with tools for its construction, gives some idea of the great work necessary in the transportation of oil. The uses of petroleum are manifold. The most recent product is a colorless, odorless, tasteless 'petrolatum,' used for lubricating the human digestive tract; the war having stopped the importation of this product from Russia, it is now made in America for the first time.

Adjoining the Standard Oil display are four gigantic dinosaurs guarding the model of the Lakeview gusher in the exhibit of the Union Oil Co. These lizards lived in the Cretaceous period. They have been constructed to testify that the officials of the company believe in the organic origin of oil—a theory that has the support of most scientists. The Lakeview was the greatest of Californian gushers, its maximum production was 75,000 bbl. per day, and a total yield of 10,000,000 bbl. This is a large quantity of oil, but was greatly exceeded by the Baku wells in Russia, where the early operators were ruined by the rivers of sand that flowed from their wells and covered valuable farm-land.

It is fitting that the United States Steel Corporation, which employs 228,000 men, and has an income of over $519,000,000, should occupy 42,000 sq. ft. (nearly an acre) of floor-space, one-fifth of the entire Mine building. Models of furnaces, mines, ore-docks, and many models of towns give a slight idea of the extent of its activities. Safety-first signs in many languages, and photographs of safety-devices, show something of the watchful care for employees. A pamphlet contains reproductions of hundreds of photographs of houses with gardens, kindergartens, pensioners, cooking-schools, and sanitary arrangements from primitive to complex. For the mining engineer the model of the Sauntry-Alpena open-pit mine is awe-inspiring in its immensity, with the steam-shovels and railway trains. As you study these gigantic mines soft waves of music flood you with harmony. They come from an organ and harp that contain pipes and wires made by subsidiary companies of the Corporation. Motion pictures of mining, transportation, smelting, and manufacturing iron and steel are shown for eight hours each day. The whole exhibit requires hours of study.

New labor laws, which include hours of working, wages, and compensation for injury, are much discussed by mine-owners at present, and to those of a statistical turn of mind, the Prudential Insurance Co. offers a series of 200 charts dealing with disease, death, and other cheerful subjects connected with life insurance. The method of showing the combination of three variables on a plane surface is ingenious, and worthy of the attention of the mining engineer. For example, one of these charts shows the weight, age, and number of deaths from tuberculosis; by the side of this hangs a chart showing similar statistics for heart disease. The differences between the sufferers from these two diseases is brought out with startling clearness. An interesting pamphlet gives the documentary history of insurance. The earliest recorded legislation, the Rhodian sea law of 1000 B. C. still governs the construction of all maritime contracts to the present day. The Aetna Insurance Co. displays a number of safety-first devices.

The object of most work is monetary gain, and a model mint is in operation in the building, at certain hours of the day. Here may be seen bars of gold, silver, copper, and nickel used in coining; a gas-fired melting-furnace, rolling-mill, strip-shears, cutting-press, annealing-machine, washing barrel, and a minting-machine. During August this plant coined $100,050 of $50 pieces.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Copper containing about 10% nickel has a high tensile strength, with high ductility and reduction of area.

Cyanicides are substances that decompose active cyanides, forming compounds which are not solvents of gold and silver.

Square-set and shrinkage-stopes are probably the easiest to ventilate. This has been found to be the case at the Copper Queen mine.

Amalgamation of gold and silver ores accounts for 8% of the United States quicksilver production. California mills use over 50% of this amount.

Most of the oil produced in northeastern Mexico is from gushers, over 90% coming from about six wells. Under present conditions a pumping-well in the Republic is not commercially profitable.

Tin, tungsten, uranium, tantalum, niobium, and probably molybdenum, occur more frequently in acid rocks, while iron, manganese, nickel, cobalt, chromium, and platinum occur more generally in basic rocks; the two last particularly in peridotite.

Heating solutions to 90° temperatue at the Tonopah-Belmont mill, in addition to increasing the ultimate extraction about 2%, facilitates the coagulation of the slime, being of benefit in the settling and increasing the rate of percolation in the final filtering.

Frozen ground in Alaska varies in depth; it is less on the ridges than in the valleys. A shaft sunk on the ridge south of Eldorado creek reached unfrozen ground at 60 ft., while one in the valley of the same creek was stopped by running water at a depth of a little over 200 ft. The ice is of great advantage from the point of view of pumping.

Fracture in rocks results from tension, compression, and torsion. Tectonic fissures arise from causes outside the rocks in which the effect is produced. These are called 'exokinetic' and generally occur in connection with orogenic, or mountain-making, processes. 'Endokinetic' fissures depend upon causes arising within the rock itself.

Experience in ventilation at the Copper Queen mine has shown so far that in poorly ventilated areas, comfort, efficiency, and economy are obtained in increasing the natural air-supply with mechanical means until the following conditions are obtained: temperature, 77° F.; relative humidity, under 85%; velocity of air in working places at least 100 ft. per minute; volume of air in working places at least 250 cu. ft. per man, per minute. This may be termed a good working atmosphere and is the present standard for mines at Bisbee.

Three prime requisites necessary for the combustion of gases discharged in the fire-box of a boiler are as follows: (1) a sufficient supply of free air in the fire-box and intermixed with the gases; (2) a sufficient temperature at the point and moment of ignition; and (3) sufficient room for the expansion of the burning gases during the act of their combustion.

Estimates of the thickness of the earth's crust have been made by comparing the rise of temperature in depth with the rise of the melting-points of minerals under pressure. The results thus obtained vary between 25 and 90 miles. According to the view generally accepted, both pressure and temperature gradually increase toward the centre of the earth. The conclusion may consequently be drawn that in the interior the critical temperature of all compounds will be passed. According to Arrhenius the material present will, on account of the tremendous pressure, be in an extremely viscous condition, which he described as that of gases compressed to the rigidity of iron.

The oil-deposit in the Furbero field, State of Vera Cruz, Mexico, is of a type hitherto unknown. The igneous nature of the so-called 'sand' encountered in drilling was not recognized until a number of wells had been drilled. It was not until recently, according to E. Degolyer, that the geological relations of the sill or laccolith, which gives rise to the accumulation of oil, were known and the so-called 'anticline' was found to be, in part, the result of igneous intrusion. The determining factor in the accumulation of oil has been the providing of pore space for a reservoir by the metamorphism, accompanying the igneous intrusion, of the under or overlying shale, which were previously impervious.

Rats have been fed by the Chinese in their coal mines as guardians. When there is danger the rats leave the mine, and the miners, noticing this departure, flee also and are saved. From a French paper we learn that an inventive American has made the rat even more useful in coal mines. This use depends on the susceptibility of the rat to fire-damp and other poisonous gases. A vigorous rat is chosen and put in a cage containing a treadmill that is connected with a little dynamo. When the rat runs on the tread-mill the electric current generated lights a lamp; a morsel of strong-smelling cheese is the attraction for the rat. As long as the rat is well, he runs and the lamp shines, but when the gas weakens him the light grows dim. Thus the proportion of gas can be told by the candle-power of the lamp. If the lamp goes out, it is a sign that there is danger, and a general alarm is given. Naturally the rat does not work all the time, but has his regular shift; so several rats must be provided. In order to keep the rat in good condition his food must be carefully regulated; overfeeding makes him lazy.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

GOLDFIELD, NEVADA

JUMBO EXTENSION, MERGER, AND REORGANIZED KEWANAS MINES DEVELOPMENTS.

Ore shipments from the Jumbo Extension mine continue at the rate of 80 tons per day, averaging $40 to $50 per ton. Two developments of interest have been reported during the past week. The shale-contact ore-channel has been penetrated by a south cross-cut from the 526-A raise, being the farthest point to the southeast at which the contact-channel has been exposed and the farthest workings in this direction. The cross-cut shows a face of ore assaying over $60 per ton. This discovery establishes the continuity of the rich ore for a considerably longer distance than had been proved, and affords further evidence that the course of the ore-channel is southeast, directly toward the southern part of the Sunflower claim of the Merger Mines Co. In earlier development it appeared that the ore must extend almost directly south, toward the St. Ives claim, and the trend farther to the east is important to the Jumbo Extension company, as it gives the latter more than 200 ft. greater distance on the ore. The new find, with intervening raises and drifts, proves this orebody over a distance of more than 550 ft., on the dip of the shale, below the new branch raise above the rich 524 drift, on the 880-ft. level. The elevation of the new discovery makes it doubtful if the Jumbo Extension will find the contact ore at all on its 1017-ft. or deepest level, and it is thonght that it may pass out of the Velvet claim and into the Sunflower above this depth. This, however, would facilitate the extraction of the ore within Jumbo ground, as it would involve no sinking below the present bottom level of the mine. The second discovery of importance has been made near the centre of the more fully developed part of the mine. In developing the main ore-channel, south and east of the first discoveries, raises were driven from the southeast cross-cut, within the shale, on the 1017-ft. level. Raise 503-A was driven to connect with the main 921-ft. level, where rich ore was first found on the shale-contact. Raise 503-B exposed the ore, on the contact, near the point where the main lode enters and appears to form a wide fissure within the shale. Some of the richest ore was found here. Raise 503-C penetrated this fissure and progressed for 18 ft. in ore of good grade. For a width of 12 ft. the ore was of medium grade and the remainder, 6 ft. on the hanging-wall side, was very rich at this point. Raises D and E have since been driven to the contact, exposing high-grade ore, the series of raises covering a distance of over 350 ft. An east cross-cut from the 503-C raise was recently started, 45 ft. above the 1017-ft. level and into the shale foot-wall of the fissure, below the pay ore. This cross-cut has demonstrated a more extensive fracturing of the shale than was suspected to exist and a high degree of enrichment throughout the fractured area, the cross-cut having exposed ore of excellent grade well within the shale. Mr. Turner regards this discovery as significant, and it may lead to additional ore in this part of the mine. The great width of the contact ore-channel is further attested by good ore found in new workings from a raise 150 ft. west of the Velvet boundary, in the Paloverde claim, approximately 400 ft. west of the new discovery in the south cross-cut. Stoping is confined altogether to the ore within the shale, as the ground about these stopes is moving, and all ore that will yield a profit is being extracted here, in order that the stopes may be filled and the ground be properly preserved for the future extraction of lower-grade ore. A cross-cut will be driven on the 1017-ft. level, from the south end of the south cross-cut, near the southwest corner of the Paloverde claim, across this claim and a large part of the Velvet claim, and to a point under the Velvet shaft, which is now being sunk to reach the 1017-ft. level. This shaft, for which high-class equipment was provided, has passed the 400-ft. point, and should be completed by the end of the year, when the hoisting capacity of the mine will be more than doubled.

In the Merger Mines property the east drift on the 1175-ft. level, which had been following the shale contact in quest of the Jumbo Extension ore-channel, and which entered a hill of shale, has again penetrated the contact zone. From present indications in the Jnmbo Extension workings, it appears likely that the Merger will be compelled to drive considerably farther than was formerly supposed to reach the Jumbo orebody.

Interest is gaining in the Reorganized Kewanas company's property as the result of a discovery made during the week. A cross-cut driven east from the north drift, in the latite, has exposed a vein that shows a seam from 2 to 3 ft. wide, assaying around $28 per ton. This may prove to be within the shale contact-zone, as the workings have been on the shale, only having lately left the shale, and have been progressing through latite. The ore contains some copper, and is said to be similar to that of the Jumbo Extension. The work of the Kewanas company is conducted through the Laguna shaft of the Goldfield Consolidated. A cross-cut was driven east, into Kewanas ground, at the 700-ft. level of the Laguna, and a winze was sunk 140 ft. where it exposed the shale and where the lateral work of the Kewanas has been carried on.

CRIPPLE CREEK, COLORADO

GOLD OUTPUT.—ISABELLA PRODUCTION.—ORE-HAULAGE RATES.—RICH ORE IN THE CRESSON AGAIN.

The estimated production of the district in August, as reported by mills and smelters, is as follows:

Where produced.	Tons.	Average value.	Total value.
Golden Cycle, Colorado City ..	38,000	$19.00	$722,000
Portland, Colorado City	10,500	21.00	220,500
Portland, Cripple Creek	19,600	2.59	50,764
Portland-Independence	11,000	2.60	28,600
Kavanaugh-Jo Dandy	1,000	1.60	1,600
Gaylord-Dante	700	4.00	2,800
Smelters, Pueblo and Denver ..	4,000	55.00	220,000
Total	84,800	$14.69	$1,246,264

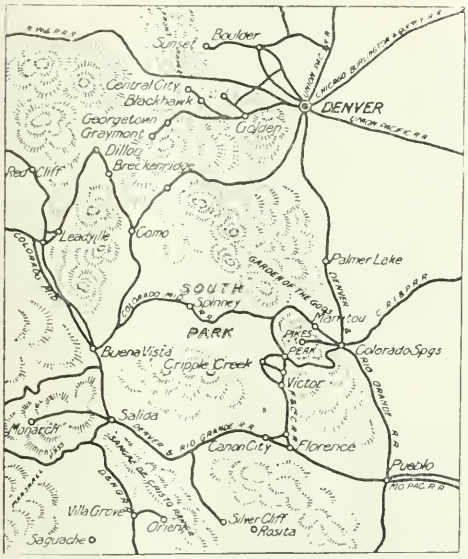
The tonnage was one of the largest recorded; the grade was somewhat lower. The Gaylord and Kavanaugh were the only small mills in operation, and they were not worked full time. It is expected that the Ajax and Jerry Johnson mills will be running before the end of September.

The period has been a busy one at the Isabella mine. It is reported that about 100 cars of ore were shipped. The superintendent Mr. Mitchell, claims that this quantity exceeded by 15 cars any other monthly production since he was placed in charge.

In a recent decision handed down by the Public Utilities Commission of the State of Colorado, the Cripple Creek and Colorado Springs railway has been ordered to reduce its rates

on ore of a greater value than $20 per ton so far as connected with mills in the Cripple Creek district. This means that on ore having a value of $20 or over, the Commission has decided that the rate of delivery to the mills be 25c. per ton less than that charged for hauling the products of the mines to the mills at Colorado City. The new rates will become effective not later than September 19, 1915.

It is reported that another rich development has been made in the Cresson mine. While little inside information can be secured, there is no doubt that the company is sacking high-grade ore. It is very probable that it is the downward extension of the famous shoot found last fall at 1200 feet.



MAP SHOWING RAILROAD FROM CRIPPLE CREEK DISTRICT TO COLORADO SPRINGS.

LORDSBURG, NEW MEXICO

NORMAL WORK IN THE STATE.—CHINO AND BURRO MOUNTAIN COPPER MINES.—MOGOLLON ROADS.—EIGHTY-FIVE MINE.—STEINS, PINOS ALTOS, HANOVER, AND RED RIVER DISTRICTS.

Steady progress has characterized the larger mining centres of New Mexico during the past six months; there has been no noticeable increase in the State's mineral production, neither has there been any decrease.

The Chino company is treating nearly 8000 tons of ore daily. It is making general improvements at its power-house. The company is also working on a new wage-scale, employees being paid according to the price of copper.

The Burro Mountain Copper Co. is making rapid progress at its new townsite, grading being under way at present. The spur to the site has been completed, and supplies are now being hauled over it. The 1000-ton mill is under construction, and steel framework erection is employing a large number of men at the mine. It is probable that the company will add to the list of Phelps-Dodge producers by the first of the new year. A recovery of about 79.80% of the metal contents of the Burro Mountain ore is expected. The company is over-run with labor of all classes, and men seeking positions are warned away from Tyrone.

In the Mogollon district of Socorro county the mines are maintaining their usual output of gold-silver concentrates and bullion. Several important transactions in the purchase of property have been made, but this has not materially affected the mineral output of the Mogollons. A question of importance to the operators is that of more adequate transportation facilities as mentioned in the PRESS of September 1. Three entrances into the district are under investigation. Three hundred men are at work on the State highway authorized by the last New Mexico legislature from Magdalena to Mogollon, which will be known as the northern route. This is not well favored by the operating companies of Mogollon. The latest suggestion, and one that is receiving support, is a proposed road from Lordsburg and Clifton, Arizona, by way of Jackson, New Mexico, into the district. This would open the Gila River country of Arizona into the Mogollon district, and lessen the cost of hay, grain, and oil. Bids are being called by the commissioners of Grant county for the erection of a bridge across the Gila river on the Silver City-Mogollon route. It seems evident that some new route into the Mogollons will be permanently established before long.

In the Lordsburg district the Eighty-Five M. Co. is exploring ground below the 450-ft. level with a Smith-Travers diamond-drill. The machine will also do other work in the district. The company has just started a new electric hoist (Ottumwa), replacing a gasoline engine. The caterpillar tractors for hauling ore from the Eighty-Five mine to Lordsburg have been moved to Safford, Arizona, where they will transport material from the Graham mountains.

The Cobre Negra mine of the Susquehanna Copper Co. at Lordsburg is under option to Faris V. Bush. The mine is developed to 300 ft., and was a large producer of copper carbonate ore above water-level. The ore also contained high gold-content.

Steins is active and several high-grade copper discoveries have caused an influx into the district.——The Johnny Bull Extension has been leased to John Moffitt of El Paso, Texas. ——The Oldan is being profitably worked by William Charles, who is making regular shipments to the El Paso smelter.—— The Panama, Coil, and other mines are being operated with satisfactory results.

New companies to be incorporated in New Mexico within the past two weeks are the Meeker Mining Co. of Pinos Altos (Peterson, Esplane, and others), and the Gold Star Miuing & Milling Co. of Albuquerque.

In the Pinos Altos district Stauber and Wright are successfully operating their mill on complex ore. There is little activity besides this.——The Hardscrabble mine, north of Pinos Altos, is giving excellent returns to J. T. James and associates of Bisbee, Arizona. A recent shipment yielded $1210 per car at El Paso. The ore averaged 40 oz. silver, 17.50% copper, 2% lead, 16.3% iron, and 32% silica. A large amount of money has been spent on the property, and several sections have been put on the market for lease and sale.

At Hanover, the Empire Zinc Co. has commenced work on the new electric power-house to operate the mines and a proposed mill.——Above Hanover, J. W. Bible is preparing the Modoc mine of the Phelps-Dodge company for extensive work. ——The United States Copper Co. is to begin operations at the Philadelphia mine within a short time. The company has had financial troubles, but is now reported to have plenty of money to deepen the main shaft and other work to prove the value of its ground.——J. I. McCullogh and L. M. Stiles, with other El Paso men are reported to have bought the Torpedo mine; and Organ, New Mexico, people are to begin work before long.

The Red River district of Taos county is undergoing extensive development preparatory to the erection of mills. The Buffalo New Mexico Mining Co. is sinking on the Silver King vein at the rate of four feet per day, the present depth being 170 ft.——The Memphis-Red River Mining Co. is down 90 ft. on its vein, where there is two feet of $30 ore.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Chisana

According to T. W. Hocker of Cordova, very little gold was extracted at Chisana this season. There is plenty of water, but little activity. He predicts that the place will be deserted next summer.

A writer in the *Cordova Times* considers that future prospects of the Chisana district are discouraging. From 1913 to August 12, 1915, the James-Nelson claims had yielded $155,715. There was only 250 ft. of ground remaining to be worked on No. 6. The total output of the region for the season will be about $135,000. The James-Nelson people are digging a ditch to sluice the Hamshaw and other ground. Not over 50 people will winter there; many are preparing to leave.

Cordova

Rich copper ore, an extension of the wide shoot at 500 ft. depth in the Bonanza mine, has been opened at 600 ft. The increase in value of the property is estimated at $6,000,000.

Juneau

Suit has been commenced by C. Goldstein, F. B. Hyden, A. D. Nash, and J. Welch against the Alaska Gold Belt Co., alleging that the defendant is not owner of 11 claims in upper Sheep Creek basin.

July returns of the Treadwell group totaled $239,864; details will appear in the next issue.

ARIZONA

Mohave County

The cross-cut at 400 ft. on the Black Eagle section of the Tom Reed mine has passed through 35 ft. of ore. Of this, 14 ft. assays $20, 30 ft. averages $25, and five feet on the hanging wall is worth $7.80 per ton. Drifts have been started on the vein. At 1075 ft. in the Tom Reed the shoot is 225 ft. long on the west, being from 15 to 20 ft. wide, and assaying from $22.50 to $40 per ton.

The United Eastern is shipping 20 tons of ore daily to the Gold Road mill. Development continues to open plenty of good ore.——Work in the Carter has been encouraging, and the shoot should soon be cut at 250 ft.——The Good Ore mine is expected to resume ore production at an early date. A fine shoot has been opened at 530 ft.——At 350 ft. in the Gold Reed incline shaft ore showing free gold was cut. Driving has been started at 375 ft. At Chloride the Payroll gold-silver-lead mine has been unwatered.——The Rainbow, in the same district, is to be examined.

Yavapai County

The Brookshire and Treadwell properties in the Jerome district have been sold for about $1,000,000. The Clift mine is included in the deal. Work is to commence at once.

About 20,000 tons of tailing at the Crown King mill, containing about $150,000 of gold and zinc, has been acquired by M. P. Randolph and D. B. Gemmill. A plant at Superior is to be moved to Crown King to treat the dump.

Fifty tons of 56% copper ore was sent from the United Verde Extension mine to the smelter at Douglas. This shipment will net about $8000.

After being in continuous operation since early in 1886, the old smelter of the United Verde Copper Co. at Jerome was closed on August 21. There was a large gathering present to witness the final run. The new plant at Clarkdale has assumed the duties of the Jerome smelter.

CALIFORNIA

Butte County

It is proposed to construct a dam ¾ mile above Oroville to act as a restraining structure, and so permit the resumption of the hydraulicking in Butte, Yuba, Plumas, and Sierra counties. The silt is to be pumped over the dredge tailing at Oroville, and so make it of value. H. R. Berkey of Sierra county is in Sacramento arranging for the details to be submitted to the Governor. The dam would be 72 ft. high, several hundred feet long, and would cost $1,000,000.

Calaveras County

According to the general manager of the Calaveras Copper Co., S. M. Levy, the mine is in excellent condition. The stope on No. 4 level, south of the Union No. 1 shaft, is in 225 ft. in average grade ore. Plans are being prepared for a new ore-house, increased grinding plant, and a filter-press.

Eldorado County

The two-stamp mill at the O. W. Jackson mine north of Mosquito, Georgetown district, recently yielded gold worth $1600.

Modoc County

The High Grade district has been examined by W. B. Tucker of the State Mining Bureau. He considers the present situation as encouraging.

Nevada County

The Golden Center company has declared a dividend of 4%.

A number of improvements are being made to the surface equipment at the Golden Center mine. A 100-ft. head-frame and new hoist are part of the plant.

Placer County

A dredge costing $75,000 is to be built at Gautier bridge by T. Donahue and others from Seattle. They have secured four miles of Bear river above and below Dog Bar bridge.

Shasta County

The first shipment of ore, five carloads, from the Balaklala copper mine to the Mammoth smelter at Kennett was made on September 1. There are 125 men employed at the mine.

COLORADO

Eagle County

Gold has been found at the head of Brush creek near Thomasville. Prospecting has been active in the district for some time. There is nothing new from the Eagle silver district, where are the Lady Belle and Lady Belle Extension.

Lake County (Leadville)

At the Penrose shaft the water was down to 516 ft. from the collar on August 29.——The zinc-oxide plant is working at capacity. The product contains from 75 to 80% zinc, while the residue has been reduced from 10 to 3% metal.——Local men have a lease on the Reveille and Pilot gold claims in upper California gulch.——A mill is to be erected to treat ores from the Garbut and Ibex No. 3 mines.——The Bwichcogh mill is working well.

Gilpin County

In the Mammoth-Kansas vein on Quartz hill water is standing at the 525-ft. level, and at 600 ft. from the surface in the Ophir shaft. The water is receding slowly. The shaft on this vein is 1450 ft. deep. Some $10 to $20 ore has been opened on the Kansas vein——The Concrete mine is being re-opened. R.

Sayre of Blackhawk has received backing from Denver people. ——In August, lessees at the Frontenac shipped 75 cars of concentrate and four of smelting ore.——The Bates, Ingalls, and other leasing companies are getting good returns.——The Pittsburg, in lower Russell gulch, shipped five lots in August, as follows:

Tons.	Gold per ton, oz.	Silver per ton, oz.	Copper, per cent.
16.3	4.18	6.75	6.25
8.5	4.45	7.39	6.10
12.1	4.72	7.50	6.20
13.1	6.30	7.00	6.20
8.2	9.49	12.00	17.20

Last week the mining property of the Pewabic Consolidated Mines Co., in bankruptcy, was sold to W. F. Gray of Blackhawk, operating the Coeur d'Alene mine on Academy hill, for $30,500. The property is fully equipped and in good order.

Ouray County

During July the Camp Bird mine produced 2668 tons of ore which yielded a profit of $62,000.——On August 28 several old buildings at the Revenue mine, recently acquired by the St. John Mining Co., of London, were destroyed by fire.

Park County

The London mine, worked under lease in charge of C. Aicher, is producing rich gold ore.——There are 60 lessees employed, most of them on good ore. Leadville people are largely interested.

IDAHO

Shoshone County (Coeur d'Alene)

The Hercules mine and mill, closed since May 29 on account of the smelting contract, have resumed work. The Northport smelter is being re-modeled to treat ore and concentrate from the Hercules and Tamarack & Custer mines controlled by the Days.

The Coeur d'Alene Antimony Mining Co., which has acquired the Antimony mine, on Pine creek, near Kellogg, has men at work re-timbering the shaft, preparatory to unwatering the property, according to W. H. Bourke of Spokane, fiscal agent for the corporation. Pumping and hoisting machinery have been delivered at the mine, and probably will be installed in a few days. A previous operator produced a good deal of high-grade ore.

Control of the Interstate-Callahan Consolidated Mines Co. is the subject of a suit recently commenced. Two sets of directors and officers were elected at Duluth, Minnesota, three weeks ago, and the dispute, which is somewhat complex, is between them. The Idaho court has appointed Eugene R. Day to act as receiver and manager to protect the shareholders' interests.

The Carbonate Hill Mining Co. has bonded its property to the Butte & Superior company for $587,630. The ore-shoot recently cut has been opened for 100 feet.

MISSOURI

Jasper County

North of Miami, Oklahoma, the Picher Lead Co. is sinking five shafts, one of which has opened high-grade zinc-lead ore at 265 ft. Three 300-ton mills and one of 500-ton capacity are to be erected at the shafts.

MONTANA

Missoula County

(Special Correspondence.)—The Martina Gold Mining Co. has started its 40-ton cyanide-plant treating accumulated tailing from the stamp-mill. The company expects to operate until the beginning of winter and resume in the spring.

Nine Mile District, Martina, August 31.

Silverbow County

The Butte-Duluth Mining Co. is in financial difficulties, and is in the hands of a receiver appointed by the State court. A number of employees are owed a total of $4098, and ask for some relief. The company's engineers state that a great deal of money has been spent on equipment, and the company is now able to treat ore in the re-arranged plant.

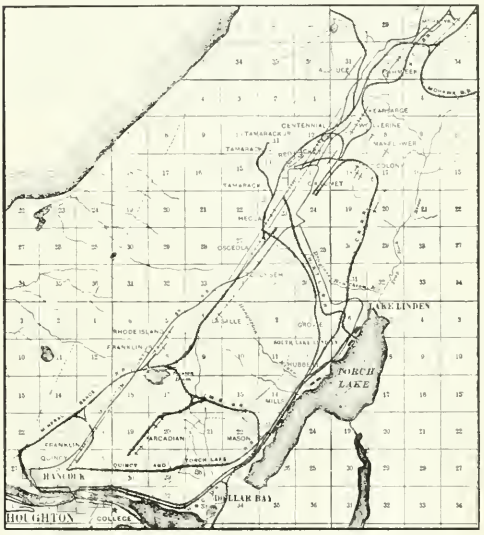
There are over 13,000 men employed at the Butte mines at present. The average wage is $3.75 per day, making a large total monthly distribution.

MICHIGAN

The Copper Country

During July the Mineral Range railroad hauled over 500,000 tons of ore from 13 mines to the mills, also mass copper direct to smelters. The Calumet & Hecla company has a large interest in this line.

In the White Pine district there are 17 diamond-drills search-



PART OF THE COPPER COUNTRY, SHOWING MINES AND RAILROAD SYSTEMS.

ing for the Nonesuch and White Pine lodes, and further proving the White Pine Extension, Onondaga, and other mines.

A second bonus of 5% was paid last week to employees of the Mohawk and Wolverine companies. Monthly bonuses will be distributed as long as copper sells at the present price.

NEVADA

Esmeralda County

The estimated production of the Goldfield Consolidated in August is as follows: Ore mined, 32,100 tons; gross extraction, $267,500; operating expense, $160,500; and net realization, $107,000.

Humboldt County

The Darby 10-stamp mill and cyanide-plant at Mazuma resumed work last week. The plant is being operated under lease by the Delaware Mining Co., which recently purchased the Delaware mine above Vernon. The ore now being treated comes from the dump, where there is 1400 tons averaging about $25 per ton. The haul from the mine to the mill is 4½ miles. H. H. Hunter, Sr., of Lovelock is responsible for the revival at these two centres.

Mineral County

Virginia City men are developing a molybdenite deposit near

Sweetwater. A lode 2 to 6 ft. wide is said to average 17 to 20% metal. Experiments are under way on the local treatment of the ore.

NYE COUNTY

Five companies and several lessees at Tonopah last week produced 9907 tons of ore worth $204,286.——There has been an improvement at 800 ft. in the Red Plume claim of the Tonopah company.——The Victor mine of the Extension company has been drained; work was resumed at 1540 ft., and 5 ft. of ore is showing in the cross-cut.——A station has been cut out at 1330 ft. in the Midway.——Fifteen sets of lessees at the Montana are employing 47 men.

UTAH

SALT LAKE COUNTY

Companies and lessees at the Little and Big Cottonwood districts continue busy and optimistic. Twenty-five men are working at the Alta Consolidated. Some rich copper ore is being opened.——The Emma copper mine is shipping two cars of ore; 26 men are employed.——The Columbus Extension has arranged for a market for its zinc ore. The last carload returned $18 per ton net.——A geological survey is to be made of the Alta Cottonwood property. The main adit is in 850 ft. toward the quartz-limestone contact.

WASHINGTON

SPOKANE COUNTY

During August the Spokane Stock Exchange business totaled 1,283,244 shares of Washington, Idaho, and British Columbia companies, valued at $200,063, a record.

STEVENS COUNTY

A contract has been let for a large quantity of lumber for the Northport smelter. While excavating in the old plant several thousand dollars worth of copper matte was unearthed.

TOOELE COUNTY

Work it to be resumed at the Le Vine-Pratt-Allen properties in Pine canyon. The adit is in 2500 ft., and is to be driven 15,600 ft. to act as a mining, transportation, and drainage tunnel for several mines in the Bingham district.

CANADA

ONTARIO

The old Wright lead-silver mine, on the Quebec side of Lake Temiskaming, is being unwatered by the Canadian Mining & Finance Co. The property has been worked at irregular intervals for 200 years.

At 200 ft. in the Tough-Oakes mine, at Kirkland Lake, No. 3 vein has been cut, showing 18 in. of ore worth $200 per ton. At 100 ft. depth the shoot was broken up. At the bottom of the winze, down below 300 ft., there is also 18 in. of $600 ore.

YUKON

On August 17 Dawson appropriately celebrated the nineteenth anniversary of the discovery of gold in the Klondike. The *Dawson Daily News* published a special edition. From 1885 to 1915, inclusive, the current year being estimated, the total output is $185,000,000. (Alaska has yielded $265,000,000, including 1915.) A total of 6236 placer claims were in good standing at the end of March 1915. Of these, 5350 were in the Dawson district, 456 in Sixtymile, 245 in Duncan, 53 in Whitehorse, and 132 in Kluane. Quartz claims aggregated 910, of which 466 were at Dawson, 199 at Duncan, 85 at Whitehorse, 8 at Kluane, and 52 at Conrad. To August, there were 162 claims crown granted.

MEXICO

HIDALGO

During July the Santa Gertrudis mine yielded a profit of $2300 from 6500 tons of ore. On account of shortage of lime, treatment was suspended from July 12 to early in August.

PERSONAL

LEON J. PEPPERBERG is in Texas.

R. M. RAYMOND has gone to El Paso.

KARL EILERS is at the Fairmont hotel.

P. E. O. CARR is at San Antonio, Texas.

GEORGE OTIS SMITH is at the Stewart hotel.

F. LYNWOOD GARRISON is at the Colonial hotel.

H. L. SWAIN, of Baldwin & Swain, is here from Mexico City.

O. C. RALSTON, of the Bureau of Mines, Salt Lake City, is here.

W. E. SIMPSON and G. A. DENNY have gone to London from Mexico.

HARRY OAKES, of Kirkland Lake, Ontario, is visiting the Exposition.

THOMAS H. TULLOCH will be at Superior, Arizona, for about two months.

L. C. HARRINGTON, of the University of North Dakota, is at Ketchikan, Alaska.

W. MOTHERWELL has gone to Colorado Springs, and expects to remain there for several months.

F. SOMMER SCHMIDT passed through San Francisco on his way from Latouche island, Alaska, to Salt Lake City.

E. K. SOPER, recently in the University of Minnesota, has been appointed Professor of Mining in the University of Idaho.

F. C. FRENCH, who has been for the past three years with the Butte & Superior Copper Co., at Butte, has returned to Salt Lake City.

P. R. BRADLEY, manager of the Alaska Treadwell, and STANLY EASTON, manager of the Bunker Hill & Sullivan mine, are expected to attend the Engineering Congress.

FRANK L. SIZER has retired as superintendent for the Mascot Copper Co., Arizona, but will continue to act in the capacity of consulting engineer to the company, with an office in San Francisco.

Among those who will arrive on the special train of the engineering societies from New York, due on the 15th inst., will be W. L. SAUNDERS, BRADLEY STOUGHTON, JOSEPH B. TYRRELL, R. V. NORRIS, MARTIN L. GRIFFIN, EDWIN LUDLOW, EUGENIO AGUILERA, J. B. HARPER, ROBERT H. RICHARDS, BURR A. ROBINSON, T. H. O'BRIEN, R. A. WALTER, L. D. BURLINGAME, GEORGE S. PAGE, GUILLIAEM AERTSEN, S. M. PITMAN, WALTER HARVEY WEED, C. G. MEMMINGER, SIDNEY J. JENNINGS, and C. E. TURNER.

On the train from New Orleans will be NELSON B. GATCH, W. ROGERS WADE, E. NORRIS HOBART, R. B. STANFORD, JOHN H. BERNHARD, and B. H. CASE.

Schools and Societies

The College of Mines and Engineering of the UNIVERSITY OF ARIZONA at Tucson will commence a 10 weeks' course for miners on October 4. It will be thoroughly practical.

Invitations have been sent by the AMERICAN ASSOCIATION OF ENGINEERS to the engineering departments of all the principal railroads, corporations, and firms in the city of Chicago to attend a booster dinner to be held at the Hotel LaSalle on September 14. F. H. Newell, head of the department of civil engineering at the University of Illinois, and who until recently was director of the U. S. Reclamation Service, will speak at this dinner on the 'Needs of Organization Among Engineers.' The aims of the Association is to raise the standard of ethics of the engineering profession, and to promote the economic and social welfare of engineers. A 30% increase in membership, drawn from engineering professions in all parts of the United States, has been registered by this organization during the past two weeks. A national convention is to be held at Chicago on December 10 and 11.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, September 9.

Antimony	35 —35¾
Electrolytic copper	18½—18¾
Pig lead	5.15— 6.10
Quicksilver (per flask)	$95
Spelter	17 —17¼
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	30

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, September 9.—The entire metal market is lifeless, and quotations are merely nominal.

COPPER

Prices of electrolytic in New York, in cents per pound.

May	13.97	18.71	Nov.	11.75	....
June	13.60	19.75	Dec.	12.75	....

Exports of copper during the week ended August 21 totaled 9,566,132 lb., worth $1,742,659. Of this, France secured 6,770,690; England, 1,413,524; Japan, 720,000; Italy, 249,587; Russia, 225,223; and Spain 128,995 lb. Imports of all kinds amounted to 4,045,285 lb., worth $691,090. England sent 979,000; Peru, 914,813; Chile, 658,090; Portuguese Africa (probably in transit), 586,550; Japan, 473,352; and Canada, 431,100 pounds.

The first shipment of copper from Chuquicamata, Chile, arrived at Savannah, Georgia, last week. It consisted of 16,878 bars weighing 70 lb. each, or a total of 1,181,460 pounds.

July outputs were as follows: Chino, 6,650,429; Nevada Consolidated, 6,292,413; Ray, 4,471,400; and Utah Copper, 14,641,000 lb. August returns were: Anaconda, 22,800,000; Old Dominion, 2,830,000; and Shannon, 950,000 pounds.

The Michigan copper country produced 26,000,000 lb. in August.

Dividends declared are: Calumet & Hecla, $15 per share; Calumet & Arizona, $1 per share; Guggenheim Exploration, 4%; Superior & Pittsburg, 38c. per share; Old Dominion, $1.50 per share; and Wolverine, $5 per share.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Sept.	2	July 28	47.29
"	3	Aug. 4	47.08
"	4	" 11	47.27

June	56.43	49.03	Dec.	49.27	....

With the improvement in exchange between New York and London there has been a stronger silver market, but the upward movement is about finished. On September 4 about 250,000 oz. was sent from San Francisco to China. During the third week of August China was a buyer of metal, but the Indian Bazaars maintained a temporizing policy, sending at intervals buying limits too low to tempt sellers.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Aug.	11	Aug. 25	95.00

It is expected that the American Zinc Co., which had a bad year in 1914, will earn $5,000,000 net during the current year. In July and August the profit was $2,000,000.

According to a consular report a firm at Hongkong is buying a good deal of spelter; previous requirements came from Germany.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.		1914.	1915
Jan.	37.85	34.40	July	31.60	37.38
Feb.	39.76	37.23	Aug.	30.20	34.37
Mch.	38.10	48.76	Sept.	33.10	....
Apr.	36.10	48.25	Oct.	30.40	....
May	33.29	39.28	Nov.	33.51	....
June	30.72	40.26	Dec.	33.60	....

On September 8 tin was quiet at 33 to 33.50 cents. With a capital of $100,000 the Standard Smelting Co. of Pittsburg has been organized by H. S. Glenn, C. E. Glenn, C. R. Buchheir, and R. S. Wile. Two Wile electric-furnaces are being erected in the old works of the R. E. Nuttall Co. to smelt Bolivian 'barrilla' (tin concentrate). The initial capacity is 6 tons of tin daily.

ANTIMONY

The market has not gained in activity or strength. The quotation for Chinese antimony has remained at 28c., duty paid. For future delivery sellers offer about 27c., in bond.

ALUMINUM

Quotations have advanced. Spot metal, 98 to 99% pure, in ton lots, is quoted at 36 to 37c., New York. For small lots excessive premiums are asked. Spot is scarce, and automobile makers are eager to get the metal. The scarcity of brass rods has caused some makers of shrapnel fuse-timers to use aluminum for certain of the parts. Tobin bronze and phosphor bronze have also been used.

Eastern Metal Market

New York, September 3.

The excited activity in copper, lead, and zinc, which developed full force on August 25 and 26, came to an end in the last days of the month. All three metals are now quiet. They show indications of softening, but so far the advances that accompanied the movement have been fairly well held. Copper producers still quote 18c. All the metals are affected adversely by the low rate of sterling exchange, which, on September 1, touched $4.50, closing at $4.55. Spelter has been uncertain, buyers withdrawing from the market with the advent of September. In three days, the A. S. & R. Co. advanced its New York lead quotation $8 per ton, making the quotation 4.90c. per lb. Second-hands are showing some disposition to take profits, but 4.90c. is still general. August deliveries of tin were large—4500 tons. Tin has been dull and prices have declined. Sellers have not been living up to the requirements of Great Britain, and the Tin Committee of the New York Metal Exchange has requested closer conformance with them, stating that infractions may jeopardize the entire arrangement under which tin is imported. Antimony remains inactive and weak. Aluminum has advanced.

The steel industry continues to prosper under the stimulus of sustained war business. Practically the entire open-hearth steel capacity of the country is under contract for the remainder of the year, and the mills are avoiding, so far as they can, contracts running into next year. There is a growing tendency on the part of all who have taken war business to say less about it; one reason for this attitude being the growing unrest of labor. Demands for the 8-hr. day and higher wages are appearing on all sides, and in most cases are being acceded to. Pig-iron continues to advance, and particularly high prices are being paid for steel-making iron. Next to the munition manufacturers, the automobile-makers appear to be the busiest class in the country.

COPPER

Three features stand out in the copper market: first, the activity that was at its height on August 25 and 26, ended on the 28th; second, while producers are still adhering to 18c., 30 days, delivered, second-hands will sell freely at substantial concessions, certainly at 17.75c., cash, New York, and probably as low as 17.50c; third, the purchasing of copper by Great Britain is seriously imperiled by the demoralization in sterling exchange which, on September 1, dropped to $4.50, although it later recovered and closed at $4.55. At $4.50 the decline represented a loss of practically 36c. from $4.8665, which is the normal equivalent of the pound sterling. [The rate has been erratic, mounting on September 3 to $4.70, then dropping to $4.64.]

Last week reference was made to the indications of activity in copper which appeared on August 24th. On the 26th the trade was particularly excited, and for a time a runaway market was threatened. A large business was done, especially at the outset of the flurry before buyers had time to think things over. When they did stop to consider, it occurred to them that the advance of 2c. in the course of a few hours was not a natural procedure, and they became more conservative. A producer is authority for the statement that American consumers led the way in the movement, and that they were followed by purchasers on foreign account. One statement made is to the effect that the rapid advance was a device to stir English buyers to activity. However that may be, it is certain that the heaviest purchasers were war contractors, here or abroad. As ammunition plants get into full swing, and more contracts are being placed steadily, more and more copper will be needed; but it remains to be seen how far this demand will compensate for the falling off in ordinary consumption. In the excitement of last week, enough Lake changed hands to establish its level at 18c. For months its quotation has been almost entirely nominal. The August exports of copper totaled only 16,289 tons. Since January 1, the exports have been 170,524 tons, against 273,365 tons, in the same period of 1914, a falling off of 102,841 tons. It should be remembered, however, that the exportation of copper contained in finished products has greatly increased. The quotations for electrolytic September 3 were 17.50 to 17.75 cents.

ZINC

At the opening of the week ended September 4 zinc was quoted at 16.50 to 17c., but subsequently the market weakened. Buyers withdrew until the situation was nominal; apparently in sympathy with the quiet conditions in the copper market. Between August 26 and 30 a large business was done, and on some sides 20c. spelter was again predicted. It is curious that during the excitement, and after it had subsided, spot zinc was exceedingly hard to procure. While the quotation at New York was about 16c., for prompt delivery, which really meant September delivery, 15.50c. was called a fair average price for last quarter delivery. By September 3, the market stood at 15c. New York, for prompt, while futures ranged from 13.50 to 14.50c. A characteristic of the present market is its uncertainty, and the rapidity with which purchasers drop out of sight before they have filled their supposed requirements. All concerned seem to be very sensitive. This is largely due to statements recently circulated with the unmasked purpose of depressing the market. Certain dealers have gone to unusual pains to show that over-production was impending, although it would seem to be to their advantage to pursue a different policy. On the other hand, statements are being made now that production will not be augmented as much as was predicted. The August exports totaled 3839 tons.

LEAD

On August 26 the A. S. & R. Co. advanced its New York quotation for 50-ton lots, $2 per ton or to 4.60c. per lb., and on the 27th it made a further advance of $4 per ton or to 4.90c. per lb, a total advance in three days of $8. As mentioned a week ago, the advance of $2 per ton, to 4.60c. (August 25) brought about a stampede on the part of buyers, and it was not checked until 4.90c. was quoted. Second-hands withdrew the low prices they had been quoting and followed the lead of the big interest. The fact that many consumers were pinched in the last bulge unquestionably restrained some of them from action on the new advance, but the fact remains that a large quantity of lead changed hands. After August 28 the market became quieter, and at least some of the second-hands then got busy taking profits on metal they had bought at around 4.50c. As a rule, however, the market, though showing some weakness in the direction alluded to, held fairly firm, and 4.90c. New York, was the general quotation on September 3. August exports totaled 2508 tons. Live war inquiries are still pending.

TIN

Deliveries into consumption in August were large, amounting to 4500 tons. Arrivals at Atlantic ports totaled 4936 tons, and those at Pacific ports destined for the East, 1100 tons. In general, business in August was slow, and prices declined. The total arrivals since January 1, 1915 are figured at 31,375 tons, against 29,900 tons in the same period of 1914. In stocks and landing on August 31 was 2527 tons, and there was afloat on that day 6170 tons. The total visible world supply August 31, 1915, was 15,127 tons, against 16,084 tons a month previous, and 14,452 tons, August 31, 1914. In the past week business has been slow, and the quotation for spot dropped on August 31 to 33.50c. New York. The average price in August was 34.37c. Early this week the market was practically at a standstill.

Engineering Exhibits at the Exposition

The following is not given as a complete directory of exhibits; it is a suggestion for the visiting engineer whose time is limited, and represents the more notable prog-

EDITORIAL

T. A. RICKARD - Editor

LOOK at page 427, on which an urgent appeal is made to you.

SINCE July 28, 1914, twenty-one declarations of war have been made. None of them has been cancelled as yet.

JOHN D. RYAN confirms the opinion expressed in these columns several weeks ago. He is reported as saying: "After the war is over there will probably be a temporary dull period followed by the best copper market the world has ever seen."

GOLD is absorbed by the United States to an extent rarely recognized. The whole of the domestic production, averaging $87,500,000 per annum for 18 years, plus imports of $12,500,000 per annum, making just $100,000,000, is absorbed in this country.

WHETHER New York is to be the money centre of the world depends not on the fall of sterling exchange, but on the restoration of it, in consequence of the ability of New York to meet the financial requirements of an abnormal epoch in international relations.

VISITORS to the Panama-Pacific Exposition are urged to see the U. S. Steel Corporation's motion-pictures, which are on view from 11 a.m. to 6 p.m. This cinema display illustrates drilling for iron ore, exploratory work, mining, transport in various forms, blast-furnaces, pipe-making, steel-shaping, and the manufacture of cement from slag.

SPEAKING of institutes and congresses, we note that a Mining Conference is to be held at Seoul, in Korea, on September 25 and 26, under the auspices of the chief of the Mining Bureau of Chosen; it is also proposed to form a Korean Mining Institute, all of which has been done on the initiative of Messrs. A. H. Collbran, E. W. Mills, and Arthur R. Weigall.

FROM our Platteville correspondent, who regularly covers this zinc-producing region of Wisconsin, we learn that the product now being made is high-grade, there being no market for concentrate containing under 58% zinc, which is in strong contrast with the low-grade material shipped prior to the recent rise in spelter and the more exacting demands of the smelters. A complete transformation has been made in treatment during a few months, showing what can be done when circumstances force a change, otherwise Platteville would be unable to sell any of its product. Among the new methods of separating zinc is the Campbell process, in which the ore is roasted before being exposed on a magnetic field, whereby the iron is removed. This process is being used at Linden, Wisconsin, with satisfactory results.

THAT big spelter production of which much has been predicted recently is being whittled down from day to day. The United States Zinc Co. reports that it is not the intention to increase the capacity of its plants. The United States Steel Corporation announces that the only zinc plant under construction on its account is the one at Donora, Pennsylvania, where 10,000 retorts will be erected. A retort produces about 4 tons of zinc per annum.

SAFETY-FIRST is being vigorously pushed at Butte. A motion-picture play has been acted on the 1600, 1700, and 2000-ft. levels of the Tramway mine and is now being shown in a local theatre. These are said to be the first moving pictures taken so deeply underground. A contest was held in Butte on September 6 between First-Aid and Mine-Rescue teams; the winning team will represent the city at the first national contest, which is to be held in San Francisco on the Exposition grounds, September 23 and 24.

CHEAP LABOR to the tyro may suggest cheap production; but the student of labor conditions and industrial history has learned that cheap labor most often indicates a high cost of production. This is well shown by shop records, where when the machinists averaged $3.28 per diem the cost per piece was $1.17, while when the average earnings were $5.74 the cost per piece dropped to 54 cents. Records of a large manufacturer having factories in Europe and America showed that for a cost of 100 in the United States the cost in Sweden was 102, in Germany 106, in France 111, and in Russia it was 133.

KOWKASH is the name of a new goldfield in Canada. Our Toronto correspondent gives particulars. The locality of the latest 'rush' or 'stampede' is in Ontario, and on the National Transcontinental railroad. The name is a merciful abbreviation of Kowawkagashkama, the name of the river near which the first discovery was made. The gold-seekers are flocking to the scene, not in prairie-schooners, on horseback, or on foot, as in former occasions of the sort, but in special trains, with Pullman dining-cars and all the comforts of home—if not better. Our correspondent quotes Mr. J. B. Tyrrell as being well impressed by the samples shown in Toronto. We

know that he has backed his opinion by going to Kowkash, so that we shall miss him at the Engineering Congress, for which he had been booked.

ONE of the expectations falsified by the War was the idea of our stock of gold becoming exhausted by shipment across the Atlantic; on the contrary, the danger lies in the opposite direction. By a fortunate coincidence our crops of wheat and cotton were both abnormally large last autumn, being 930 million bushels of the one and 17 million bales of the other, so that an amazing international balance of credit was created by the end of June this year, the sum being $1,094,000,000. Other expectations, we are thankful to say, have not been fulfilled, such as the ruin of our copper industry and the swamping of our exchanges by the liquidation of American securities from Europe. But one consequence, the necessity for big loans to our customers across the water, was not foreseen, and must be faced now. Upon it will depend the trend of human history.

SECRETARY DANIELS has a splendid advisory board for the Navy Department. The national engineering societies have nominated representative experts to contribute their inventive genius to the service of the country, under the chairmanship of Mr. Thomas A. Edison. We note with pleasure that Mr. William L. Saunders, president, and Mr. Benjamin B. Thayer, ex-president of the American Institute of Mining Engineers, have been selected as representatives of mining and metallurgy; also Messrs. Joseph W. Richards and Lawrence Addicks as exponents of electro-chemical engineering; Messrs. Peter Cooper Hewitt and Thomas Robbins as nominees of the Inventors Guild; and a number of others of equal distinction but not so well known to us or to our readers. The idea of mobilizing the talent of the country for defensive purposes is a bit of sublime common sense greatly to the credit of the Federal Administration.

WHEN we wrote on the subject of directors and speculation, we were aware that directors do speculate and do make a wrong use of information that comes to them in their official capacity. We could have quoted chapter and verse for speculations in mining shares that ran perilously near the line dividing unfairness from criminality. But we confess the bold operations of the Rock Island wreckers exceed anything in our experience. These recreants wasted $20,000,000 in unwise and improper deals "outside the proper sphere in which stockholders had a right to suppose their moneys were invested." Of this $1,000,000 was voted to the officers in the form of gratuities. The *Nation*, from which we take the above facts, states that "the crux of the whole thing lies in the attitude of directors like Daniel G. Reid, who testified that he burns his books at the end of every month, and so could not explain his profits from the various transactions in which he as a director took part." In many countries such burning of records is a criminal offense, and it should be criminal in this supposedly enlightened land. We believe that in Russia a merchant is obliged to keep his books for ten years. Such atrocities as that of Mr. Reid go far to justify the fierce attacks made on capital by demagogues like Mr. Frank P. Walsh, the ex-chairman of the Federal Industrial Relations Commission; they also account in no small measure for the savage doctrines of the I. W. W. and other anarchistic organizations.

IN a recent issue of *Science* Mr. Joseph W. Richards, an honored professor and an effective writer, makes a protest against the publication, by general scientific societies, of numerous abstruse papers on specialized research. He calls it "an anachronism of the most glaring kind." And adds, "Is it fair to any man on earth to ask him to pay for the whole set of papers in order to get the one or two which he can read understandingly and profitably? You surely cannot expect a man of understanding to risk acute mental digestion by trying to assimilate the specialized articles entirely outside of his ability to absorb. Then why should any individual be expected to pay good money for so much material useless to him?" What the Lehigh professor says of the proceedings of the National Academy of Science can be said of the publications of societies less academic in character. Pan-scientists have their counterpart in pan-technologists.

Standardization

Any serious attempt to standardize the usages and terms current in professional practice is deserving of support. The latest effort in this direction is the report of a committee appointed by the Mining and Metallurgical Society of America. That organization is small in membership, but strong in its members; so also the committee is not large, but distinguished. The recommendations are not made to the mining profession in general, but to the members of the Society, numbering about 250 engineers and geologists. As a text for its report the Committee takes the standards advocated at intervals by the Institution of Mining and Metallurgy in London. On one matter the Society's committee is in such perfect accord with the Institution that the recommendations made by the latter are adopted verbatim; we refer to the unauthorized use of publications. In regard to 'ore in sight' the Committee emphasizes the need for defining the gradation of mental vision, but does not, we regret to say, recommend the abolition of a misleading phrase. No ore is 'in sight' until it is in a bin, if then; it was a pity therefore that the other common terms, such as 'in reserve,' 'blocked out,' 'assured,' and so forth, were not passed in review, with recommendations to adopt those that are most nearly descriptive of the various stages of assurance involved in the act of estimation. The Institution prescribed that the engineer "should demonstrate that the 'ore' so denominated is capable of being profitably extracted under the working conditions obtaining in the district." Surely this was a

wise provision; what is the use of estimating the tonnage in a block of ground until it has been explained clearly how much of it, and why, is 'ore,' that is, lode-matter from which a profit can be won at the end of the operations anticipated. It is true the Committee asks the engineer to "clearly define what is meant in the report by the terms 'ore in sight,' 'ore blocked out,' or such other general terms as he may use referring to the quantity and quality of the ore," but the Committee itself has failed to "clearly define" what it means by 'ore,' for 'quantity' and 'quality' mean nothing without reference to the cost of exploitation and realization. As regards screens, the Committee rejects the Institution's standards, founded on wires and openings of equal size, preferring instead to use the Tyler scale, which is based on the size of the openings alone. The Committee believes that this is "the proper and logical basis." In the use of weights and measures, the Committee urges the adoption of the metric system in all reports dealing with South American mining enterprise; also the employment of the Centigrade thermometric scale. This is wise. In measures of water, the Committee opposes the Institution's suggestion to drop both 'miner's inch' and 'sluice-head,' in favor of definite statements of flow in cubic feet per minute. The Committee wants 'miner's inch' retained and 'sluice-head' rejected. One represents American, the other Australian, usage. Both are equally objectionable as standards of measurement. If the 'miner's inch' is to be defined as 1.5 cu. ft. per minute, why not state the number of cubic feet per minute in the first instance, and so avoid the use of a measure that varies greatly in different localities? The Committee opposes the use of the Imperial gallon, just as the Institution rejected the American gallon. Both are equally justified, and both have failed in recommending a unit suitable for international usage. As regards assay-values the Committee makes the good suggestion that "all samples should be dried at 100°C. before being subjected to assay or analysis, and that the report should definitely state that this precaution has been taken." The Committee joins with the Institution in recommending the use of the 'fluid ton' of 32 cubic feet, because it is approximately equal to the short ton, which, of course, is the standard weight. It is recommended that pennyweights and decimals thereof be "completely eliminated." Is this well? In most gold mines, where the grade of ore is normally below an ounce per ton, it is convenient to use the pennyweight because it is the equivalent of a dollar. Why accept 85 shillings and $20.67, alternatively, as "a convenient constant" for the value of an ounce of fine gold? The Institution and the Committee concur on this point. An ounce of fine gold is worth slightly less than 85s.; why then use the exact sum, $20.67, as the equivalent? Why not $20, which is a more convenient constant, and the one actually in general use? The difference between $20.67 and $20 is less than the margin of error in the estimation of the average assay-value of the ore in a gold mine. By way of further remark we may say that all standardization committees are in jeopardy of criticism, therefore we venture to suggest that this Committee should have tried to avoid issuing a "partial" report; it should have been impartial. Perhaps it was intended to say that the report was incomplete. The last of six headings is called "the latter"; that is contrary to Hoyle and other authorities on the game. The Committee says: "We recommend concerning the use of this term the following." We recommend that the sentence be torpedoed and that the *disjecta membra* be re-arranged in orderly sequence. "The infraction of this resolution" suggests something heinous; the gentlemen of the Committee probably mean 'the disregard of this regulation.' However, for fear of being deemed frivolous we shall close these remarks in more serious vein. We recognize the good purpose, and the probably good results, of the Committee's efforts. Therefore, we urge them to go a step further. Why not mobilize a joint committee of the leading mining engineering societies with a view to advancing the cause of standardization? Otherwise, only confusion will result. Of course, the Committee above-mentioned can say that its recommendations are not intended for the profession at large, but some engineers are members both of the Institution and the Society that have made these praiseworthy efforts to standardize. Moreover, the secretary of the Mining and Metallurgical Society of America announces that he expects the co-operation of the Canadian Mining Institute. Why not organize a committee to represent the two societies just mentioned, the Institution of Mining and Metallurgy, and the American Institute of Mining Engineers? The joint committee of the four leading societies would be in a position then to recommend standards that should be honored by all mining engineers speaking the same language. The gentlemen whose report we have discussed are amply competent to take a lead in the matter.

American Mining Congress

To live is an accomplishment: to survive is a feat. Men and organizations alike gain in reputation by mere persistence of effort. The unfit disappear; the morally weak cease to exert influence. As we recall the early days of the Mining Congress, its dubious character and its uncertain scope, and now recognize its strength of purpose and assured position, we are moved to congratulate the founders and their successors. Turning to our back volumes we find the progress of the Congress recorded year by year. It was organized, and convened for the first time, eighteen years ago. The idea was born, if we remember correctly, in Gilpin county, Colorado. The agitation for the free coinage of silver was at its height and the worthy citizens of Gilpin thought it well to remind the world that gold was important also. So they sounded the call for a 'Gold Mining Convention.' On July 7, 1897, the delegates assembled at Denver, but they had hardly concluded the preliminaries before the stereotyped free coinage resolution was passed by acclamation. Whereupon the Gilpin delegates, much cha-

grined, walked out. The Congress was abandoned by its originators and beeame something quite different from what they had planned. At a later date it barely escaped capture by the Western Federation of Miners. So it has had a chequered career. At its start, and for five years thereafter, it was known as the International Mining Congress, a grandiose title that belied any useful purpose within its power to accomplish. In those days, in absurd contrast with its name, the principal propaganda of the Congress was the creation of a Federal Department of Mines and Mining with a Cabinet Minister at its head. Mr. Irwin Mahon was the first secretary and the guiding spirit of the organization, aided by a group of mining promoters and politicians, to whom the annual session afforded an opportunity not only for ventilating sundry schemes of governmental paternalism, but also a chance for boosting the particular mining locality in which the Congress foregathered. At those meetings a great deal of windy talk was made, pseudo-experts aired their opinions, and pompous persons won newspaper notoriety. In its third year the Congress was on the verge of collapse. At that time the following comment appeared in our pages: "The Milwaukee meeting was of no avail. If real mining men could continue to believe that their attendance would be productive of benefit they would attend even at some personal sacrifice, but the average miner is too busy a man to go a thousand miles to listen to essays by people who do not know what mining is."

Nevertheless, even these early defects did not kill the Congress, because amid the chaff there was some good grain and among those attending the suecessive conventions were some serious men. In 1902, at the Butte meeting, Mr. James H. Richards presided, and for eight years thereafter he served, with persistent zeal and loyalty, as President. To him mainly the Congress is indebted for an escape from its early divagations. He was assisted by the late Ernest R. Buckley, who succeeded him in the presidential chair, in 1910, and would have continued to be an influence for good if he had not been called away untimely. Mr. Richards brought several mining engineers of high repute into the Congress and slowly won for it a national recognition. Men like Messrs. Charles W. Goodale, S. A. Taylor, James W. Neill, James W. Malcolmson, and James W. Abbott (is there something mystic in these particular initials?) were among the first engineers to give help; then Messrs. James Douglas, David W. Brunton, Hennen Jennings, J. Parke Channing, Edmund B. Kirby, and S. W. Mudd took a hand. The United States Geological Survey was among the first to recognize the Congress, deputing various geologists to read papers. In 1908 the Director of the Survey, Mr. George Otis Smith, himself took part in the proceedings. The President was persuaded to nominate delegates as early as 1904, and in 1911 President Taft addressed the Congress when in session at Chicago. In 1906 Mr. James F. Callbreath became secretary and at the same time permanent headquarters were established at Denver, together with a bureau of enquiry, a library, and an exhibit of ores. Out of the early propaganda for a Mining Department eame the more practicable demand for a Bureau of Mines, which was established in 1910. This is to the credit of the Congress; also the fact that it endorsed the late J. A. Holmes as the first director of the Bureau. The Congress gave its support to the efforts made by the Post-office department to check the sale of stocks in fraudulent mining schemes and in 1906 drafted a bill providing for the punishment of fakers. Its efforts in this direction have not been ineffective. At the annual conventions the need for amendment and uniformity in the mining laws have been advocated by Messrs. W. R. Ingalls, Horace V. Winchell, and George W. Riter; a correction of various Alaskan regulations has been urged by Messrs. John L. Steele, Maurice D. Leehey, and Falcon Joslin. Prevention of accidents in mines, the excesses of the Forest Service, and railroad-building in Alaska were other matters that received attention at the annual sessions, with good results, for the public and the press were undoubtedly made to understand the need for reform, and members of the legislatures were given useful hints for the enactment of statutory changes.

Now the directorate of the Congress and the personnel of its committees are unexceptional, and the general character of its discussions has been raised to a dignity quite foreign to those silver-tongued harangues and boostings that used to mark the early sessions. We think the Congress deserves the general support of those engaged in mining. We need a parliament of mining operators and engineers to assemble periodically with a view to crystallizing opinion on matters of moment to the industry. To strengthen itself for its main purpose the Congress should discard its statistical work, which is being done, and done better, by the Federal bureaus; it might as well drop the enquiry department and the ore exhibit, both of which deflect its aim. No; the work that the Congress can do is plain enough. It must be an annual convention of those interested in the business of mining—the miners, superintendents, operators, capitalists, and engineers actually engaged in a great industry, together with the Government officials, professors, journalists, and others able and willing to contribute to the general stock of ideas on the subject. If the American Institute of Mining Engineers had chosen, it might have assumed leadership in all matters affecting mining, but under the guidance of Dr. Rossiter W. Raymond it early adopted the policy of keeping clear from any commitment of opinion on public affairs, so that there was room—and need—for an organization that could perform this function. None is more important. The social obligations of good citizenship call upon the members of the profession and the bigger brotherhood of all those actually engaged in mining operations to unite in giving effective support to the American Mining Congress. We hope that the San Francisco meeting, under the presidency of Mr. Carl Scholz, may be marked by a large attendance and unmistakable public support.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Big Business

The Editor:

Sir—Your editorial in the issue of July 10, and Mr. W. L. Austin's letter of July 24 induce me to give my views on the subject.

Big Business is an example of combined effort and owes its success to the union of many men, wisely guided and provided with ample capital, working efficiently for a common purpose. Among the many questions that arise concerning their operations, the most important seems to be: Is Big Business a development in harmony with the evolution of society, or is it an artificial and transitory phenomenon that will disappear like muzzle-loaders and hoop-skirts, or will it be found as necessary to the normal development of society as telephones and submarines?

Solomon advised an idle gentleman to learn from the ant and though an investigation of these little insects may not teach us much, yet it is of interest to note that they are the most numerous and perhaps the most successful forms of life that exist on earth and that much of their success is due to combination. Indeed, some entomological authorities have said that the present age really ought to be called the "ant era." The residents of Oakland and Berkeley have some faint idea of the power of combination when they encounter the tiny Argentine ant who is smaller than this letter l and yet when joined in thousands has worried and is still troubling no inconsiderable portion of the inhabitants of those bay-cities. But for really big business in the ant line one should study the long columns of the driver ant, whose onslaught no earth-dweller can resist—the ravening lion, the gigantic serpent, and man himself all flee when the driver ant approaches. This insect is perhaps the best example of big business that the world offers; unfortunately his power is used with no regard to the rights of others.

Omitting from consideration many other forms of animal combination, and turning to humanity, we find that as man develops he dwells in larger and larger communities and combines his efforts in ever-increasing masses. The history of the mechanical arts shows, first, the isolated worker in his own dwelling; later, with the invention of steam, the factory system developed and men, women, and, unhappily, children gathered together in thousands. As the latest development we see the owners of these factories, workshops, and mines combining together into Big Business. A little consideration of the history of these great combinations shows that they are a natural and helpful development of society and that an attempt to restore unlimited competition by legislation is a retrograde movement, likely to be futile as was the attempt of Mrs. Partington to brush back the swelling tide of the Atlantic with her broom.

That Big Business has abused its power is certain, but the remedy is at hand and does not lie in futile attempts to restore competition, but in regulation. The power of regulation is inherent in government and has already been exercised in regard to railways to the extent of partly destroying their credit. The principles on which the regulation of Trusts should be based are the adequate protection of the actual capital invested and the absolute destruction of unfair competition. Such consolidations as those in which the Pittsburg iron and steel manufacturers made their millions by selling their plants to the United States Steel Corporation at grossly inflated prices should be guarded against. And that form of competition wherein a Trust sells its products below cost for the purpose of compelling a competitor to join the Trust or to be forced out of business, and perhaps ruined, should be made a criminal offense. To fix the exact return that should be allowed on invested capital, having due regard to the risk involved in most business transactions, and to regulate the amount of profit legitimately due for promotion services will be a matter of great difficulty. The wit of man has accomplished more difficult tasks and there is no reason why the problem of the regulation of the Trusts cannot be solved without attempting to restore competition. The rigid rule that Trusts must be destroyed because their operations are large is based on sentiment, not on reason. Moreover, the separation of the Trusts into their component parts does not seem to have been beneficial to the consumer, who is the one to be considered. This is shown by the results of the dissolution of the Standard Oil Company, where the market value of the separate companies much exceeds that of the parent company before dissolution; this means that the total amount of the profits of the separate companies is larger than when they were united, and as the expense of operating the separate companies is much larger than that of operating the combination the total loss to the consumer is very great. The breaking up of the Tobacco Trust does not seem to have helped anybody, except the newspapers, for the price of the products is no lower and the expenses of the smaller dealers have been increased by cut-throat advertising.

In conclusion it seems plain that as consolidation makes for economy and efficiency—this is well shown

in comparing the results obtained in the anthracite fields of Pennsylvania by the large companies as compared with the smaller operators—it should be encouraged and not repressed. Consolidation, or Big Business, is a natural development and cannot be replaced by competition without great loss to society. When the powers gained by consolidation are abused; when the Trusts are unfair to competitors or become too powerful financially, or politically, they should be regulated and not destroyed.

Germany, which apparently stands at the head of the nations as regards efficiency, is not afraid of Trusts, but insists on their formation and much of her business success is due to this policy.

W. H. Shockley.

San Francisco, August 16.

The Amateur Miner

The Editor:

Sir—Since reading your editorial contained in the issue of July 31, entitled 'The Amateur Miner,' I have often thought as to what would have been my answer to Mr. Gray had he come to me for advice as to how to enter properly the mining business and continue it with pleasure and profit. The following is the result of my deliberations:

It requires a good round sum of money to acquire a mine by purchase, where usually a small sum is sufficient to secure a prospect which would justify one in expending the necessary money to develop it into a profitable producer. Judging from your description of the gentleman, he would be perfectly able financially to place in the field a prospecting party, and it would appear also that to obtain a mine in that manner will appeal to him with the greatest force—he would be able to take part in the actual finding, organizing, and operating of a mine. I would therefore have advised him to enter into arrangements with a man of experience, preferably one who has made a speciality of mining geology, not only theoretically but practically also, and engage him as the head of a small prospecting party. No doubt such a man would be willing to give his service on the basis of a small salary and in addition an interest in any mining property that was discovered and located by him. Such a prospecting party should consist of three men, the two, besides the chief, to be paid good miner's wages without any interest in discoveries, and one of these should take care of the team, do the cooking, etc. The wagon would be headquarters, and be moved from place to place as the work of prospecting progressed.

This manner of prospecting is by no means new, with the exception that it has not been my experience to see such a party headed by a responsible and trained geologist. The old way was to start out a couple of men with a wagon-load of supplies, who were then left to their own devices—no system of reports was arranged for, and indeed, such men are incapable of writing concise or intelligent statements as to the mineral occurrences in the country traversed, or the discoveries made. But with a competent man in charge, a systematic detailed account of each day's work would be recorded, and when an important discovery was made, his report would receive the intelligent consideration of his principal or any group of investors gathered together for the purpose of furnishing funds for development and equipment.

An important question would then arise as to where would be the most likely territory for the party to commence operations. No doubt the chief of the party would have some views on this subject. My own suggestion, having in mind the approach of winter, would be for the southern parts of Arizona, Nevada, and California, which I believe to be promising fields, and where prospecting can be carried on from now until next July without any particular inconvenience. At times an opportuntiy would present itself for obtaining a promising prospect which had already been discovered by others—such a contingency may well be anticipated, and advantage taken of it when offered.

The cost of such an expedition, carried out as indicated, would amount to $500 per month, and the first cost of outfitting with team, wagon, supplies, etc., would be $500 or thereabouts.

It is my candid opinion that if Mr. Gray followed the plan that I have outlined, and that a reasonable share of good fortune attended the party, he would finally become the owner of a paying mine; he would also be engaged in a clean business, a business full of adventure and health, and which is often of a highly profitable nature, and furthermore, when you next had occasion to refer to him in the columns of your paper, it would be as Mr. Gray, the mining operator, not Mr. Gray, the amateur miner.

Ernest G. Locke.

Rochester, Nev., September 1.

The Ontario Nickel Commission

The Editor:

Sir—On returning to the city after an absence of several weeks in the north, my attention was drawn to an editorial note in your issue of August 7, page 194, in reference to the Nickel Commission recently appointed by the government of the province of Ontario.

"Accidents will happen in the best regulated families," and it is not surprising to find that even the carefully and brilliantly conducted Mining and Scientific Press once in a long time falls into error. The following paragraphs are tendered as corrections:

(1) "In order to exercise greater control over the industry, the government of Ontario has appointed a commission to enquire into the feasibility of refining the nickel matte in Canada." The commission is instructed to investigate not only the refining of nickel but the whole nickel industry, including the character of the deposits in various countries and the taxation of the Ontario mines.

(2) The statement "It is fortunate that the Imperial government insisted on the appointment of an experienced metallurgist as chairman of the commission"

shows that the writer of the editorial is not cognizant of the facts. The Imperial authorities recommended the chairman at the request of the Ontario government. The Imperial government, it is scarcely necessary to say, does not assume or exercise autocratic powers. The constituent parts of the Empire not only enjoy full liberty, but the Empire by recognizing its treaty obligations and Hague conventions seeks to promote liberty throughout the world.

(3) In the last sentence it is said that "The commission looks like a sop to public sentiment, for it is extremely unlikely that its report will be applicable to any emergency created by the War." It is here assumed that the nickel situation is a new one, created by the War. Such is not the case, there having been agitations for investigations or more complete governmental control at various periods during the last 25 years. Discussions have taken place in the legislature, at the annual meetings of the Canadian Mining Institute and elsewhere.

Toronto, September 1. W. G. Miller.

The Prospector

The Editor:

Sir—In a recent article in your magazine, lent me by a friend, entitled 'Speculation in Mining,' you manifest much concern as to the lack of interest shown toward mining by the public generally. I regard your enlightened interest in the matter as a sign that the prospector may yet come back into the field from which you have helped to drive him. If you will review your issues for a few years back, and right up to July last, you will find voluntary advice to would-be investors in mining ventures to investigate by means of thoroughly trained men, and then place their money in something else. Scarcely an issue of the mining journals but contains warnings to the public. Caution is the bell-note in any magazine you may pick up. The depressed state of mining requires a less number of trained men. They are conducting street-cars, etc. This condition the prospector hails with joy. When the engineer trained by magazines to knock mines and the prospector is building county-roads, the magazine too will go. Then the prospector will return. Foundry-men will send their salesmen to him, and help out any worthy mining effort. Then, and not until then, will the public's point of view change in favor of mining.

The trouble with you magazine writers is your perspective of the mining situation is viewed from a wrong angle. Your mythical prospector with a mountain of ore for sale appeals to no one, and the highly technical language with which your mythical engineer deals a solar plexus blow to that prospector's report is not calculated to remedy existing conditions. The magazines are largely responsible for the public attitude toward mining. Caution, caution, creeps into every mining report from engineers, until the public regards us as a lot of fakers. The mining field is being combed for a prospect that has 10,000 tons of ore in sight at a nominal price. Nothing else can get past in this day of caution.

Havilah, Cal., August 31. Wm. W. Waters.

Distress in Russia—An Appeal

Just as we were going to press we received the following telegram from Mr. Edward T. McCarthy, one of the most honored men in the profession of mining. He is at Moscow, on his way from London to Siberia, and has been strongly affected by the sight of the unspeakable misery of the peasants fleeing from the War zone into Russia's old capital. We believe that this appeal will not be fruitless. Any contributions sent to this office will be forwarded promptly to the American embassy in London.

Moscow, September 13, 1915.

T. A. Rickard,

420 Market Street, San Francisco.

Have cabled Edgar asking Hoover if he would raise American fund ten thousand pounds or more help refugees pouring into Moscow. Small English community supporting hospital, hundred fifty beds. Can only feed three thousand daily, being limited by funds. Refugees mostly have only summer clothing. Accommodation, food, clothes hopelessly inadequate. Moscow already receives one-third total wounded. Authorities overwhelmed new influx refugees. Private aid alleviate awful distress. I appeal to my old American friends. Lose no time. Send succor. Excellent English organization, with co-operation American consul, doing utmost in this frightful calamity. Words fail describe terrible sufferings of these patient peasants. Immediate preparation against winter urgent. Your previous knowledge Russia enables you to realize what this means. Frisco will, I know, respond.

McCarthy, care Woolmer.
Post-office Box 19, Moscow.

[Edgar means Edgar Rickard. Hoover refers to Herbert C. Hoover, of course. Woolmer is H. C. Woolmer, consulting engineer to the Spassky and Atbasar mines.—Editor.]

Costs at the Jumbo Extension

During the year ended June 30, 1915, there was 16,420 tons of ore produced, yielding $39.64 per ton. Expenses were as follows.

Item of expense.	Per ton.
Mining	$ 3.12
Development	3.54
Milling, including freight, royalties, marketing concentrate	1.05
Freight and treatment on ore shipped	7.29
Freight and treatment on concentrate shipped	0.24
General expenses, including office, legal, corporation, administrative, etc.	2.39
Bullion tax	0.32
Construction and new equipment	1.02
Total	$18.97
Net realization	20.67

Goldfield, Nevada, produces 40% of that State's output of gold, and Tonopah 73% of the silver.

Why is Flotation?

By CHARLES T. DURELL

Some of the fundamental principles of this concentration 'upside down,' as it may be termed, being such a new method, have been overlooked. There has been such a mad scramble to get results in advance of the 'other fellow,' and to penetrate the cloud of secrecy enforced by patent litigation, that there has been little time to answer the question as to why the heavier mineral floats and the lighter gangue sinks. In this buzzing cloud of secrecy the student can distinguish such phrases as 'froth flotation,' 'surface tension,' 'oil-films,' 'DeBavay float,' 'liquid skins,' etc., all of which tend to confuse rather than answer the main question. A few articles in the magazines have given various data, phenomena, causes, and effects, but no definite theory explaining these has been clearly stated.

The action of any flotation machine in successful operation seems quite simple, the mineral floating in preference to the gangue, giving rise to the phrase 'selective flotation.' All that is necessary for the one type of machines is to place the mineral particles gently on the surface of a liquid so that they will not sink or, in the other type of machines, attach to them something of a lighter specific gravity than the liquid so that they will rise bodily to the surface. On the face of it, this is quite simple. Apparently the simplest of all is to attach 'life-preservers' or something buoyant to the mineral particles.

Herodotus describes how "the virgins drew up gold by means of feathers daubed in pitch." Therefore this or an oil, for instance, can be employed to float mineral. The Elmore patents for this flotation, due to the buoyant property of oil, are still in effect. Due to the large quantity of oil necessary, as well as other things that make this method of no commercial value at present, the only 'why' to be considered in this class of flotation is the selective action, which will be discussed later.

The simplest and cheapest 'life-preserver' is undoubtedly the pneumatic one, which is beyond the time of Herodotus or perhaps even history itself, since eggs and cream were surely frothed before the stylus was known. Any little girl who has helped her mother in the kitchen can tell how any foreign substance, such as a piece of egg-shell for instance, is buoyed up and brought to the surface by these bubbles. These are bubbles of air, and what could be cheaper for the manufacture of these simple pneumatic 'life-preservers?' It is true that Delprat, with his process, uses carbon dioxide, but this is simply a case of using a by-product that would otherwise go to waste.

Therefore the whole sum and substance of this apparently complex problem of ore concentration by flotation, now surrounded by a cloud of secrecy, consists in either attaching mineral particles to gas bubbles, preferably air, or attaching air bubbles to mineral particles. It amounts to the same thing whether the bubble be attached to the solid or the solid attached to the bubble. In the one case, a 'surface tension' type of machine is used for the concentration, while in the other a 'froth' type of machine is used. These will be taken up later.

Therefore the two prime requisites to flotation are:

1. Attachment of bubbles to solids;
2. Creation of selective action of bubbles for metallic particles instead of for the gangue particles.

Since the all-important requisite is the attachment of gas bubbles to solids, it is logical to investigate this phenomenon first with the simplest materials at hand—air and water.

Far back in primeval time the progenitors of the fishes made air bubbles that came to the surface of the water and yet we, a few years ago, knew but little more concerning air bubbles in water. There was no reason for these aquatic things knowing the ways that air can exist in water but there was no excuse for our building Pachuca tanks, blowing air in at the bottom and then writing a beautiful chemical equation to show that these air bubbles were necessary for dissolving gold. Visible bubbles of air, which have been blown into the water, can in no possible way sustain the life of a fish. Neither can they aid one iota in dissolving gold in a cyanide solution. Nor can visible bubbles of air, introduced into a liquid in this way, be attached to solids to aid in flotation. Available air or oxygen for things of this nature must be air actually in solution. A fish may be breathing freely at the bottom of an aquarium. If the water be warmed so as to expel the air, the fish will rise to the surface and try to jump out. Only nascent hydrogen can unite with arsenic in the Marsh test. In the same way, only nascent oxygen from the dissolved air can act as shown in the chemical equation:

$$2\,Au+4\,K(CN)+H_2O+O=2\,KAu(CN)_2+2KOH.$$

when gold is dissolved. Only nascent gas can be attached to mineral in the flotation process. This fact is quickly demonstrated by introducing a small jet of air into the bottom of a flask, filled with water, where rests some pulverized ore, the metallic particles of which are in a perfect float condition. Why will the mineral particles, which almost float of their own accord, refuse to attach themselves or be attached to the small bubbles of air? To prove that these same metallic particles can be floated by bubbles of air, it is only necessary to remove the jet and place the flask on a hot plate when they will immediately collect air driven out of solution by the heat and rise to the surface. Some one may here

remark, that the rise of temperature of the solution causes enough expansion of the air bubbles already attached to the metallic particles to produce flotation. Anyone familiar with the law of Henry will know this is not the case on noting the greatly increased size of the bubbles. Why, then, cannot air bubbles be attached to mineral particles in the place of nascent or dissolved air?

All great facts, when thoroughly understood, are demonstratable by simple experiments with material at hand. Sometime when the young man at the soda fountain absent-mindedly forgets to stir your cherry phosphate and sets before you the straws, demonstrate the above fact to your satisfaction while the nascent bubbles of CO_2 form and rise to the surface of the liquid. Crush the straw slightly to reduce the size so that only a minimum of air can be forced through. With this straw, blow air into the colored syrup in the bottom of the glass so as to form a few small bubbles that can be watched closely. These bubbles that come to the surface are colored. Why? The air itself is not colored. Therefore, since the only part of the liquid that is colored, is in the bottom of the glass, the air must be enveloped in the same identical portion of liquid throughout its passage from the bottom to the top of the glass. In other words, the air bubble, on being introduced into the liquid, is immediately surrounded and inclosed by a film of liquid, which remains with that air bubble throughout its passage just as if it were a part of the bubble. Here is a concrete example of surface tension, a force that can be measured, as explained in any text-book of physics.

This phenomenon is worthy of investigation. The bubble rises to the surface of the liquid by reason of the force of gravity. That is, the force of gravity is greater than adhesion of the molecules of the air for the molecules of the liquid; otherwise the air would remain in the liquid. The molecules of the liquid move freely among themselves according to the definition of a liquid. In other words, the force of cohesion of any single molecule within the liquid is equalized by the cohesive force of other molecules of the liquid. An extraneous force would be required to separate them. An air bubble, for instance, introduced into the liquid, unbalances this cohesive force. It is self-evident that this force of a molecule must act equally in all directions from that molecule. Therefore molecules of the liquid adjacent to the air bubble have their force of cohesion on the one side satisfied by that of adjacent molecules of the liquid, while, on the side of the air bubble, there are no molecules of the liquid to equalize this force. Being statical, this force must be equalized by that of adjacent like molecules in a transverse direction. Since a force of cohesion was already in existence between these adjacent molecules this force is thereby multiplied so that there then exists a greater cohesive force between the molecules immediately surrounding the air bubble than that existing between the molecules in the interior of the liquid. This force is 'surface tension;' it is so great that these molecules of the liquid surrounding the air bubble are firmly held together and torn loose from adjacent molecules of the liquid as the bubble rises to the surface. That is to say surface tension causes the molecules of the liquid to form a film around the bubble and remain with it to the exclusion of like molecules during the time the bubble remains in the liquid. To all intents and purposes, this film is seen to be the same as if it were a membrane of some solid. The air in these bubbles can no more come in contact with the liquid through which it is passing than it could were it inside a toy balloon, for instance. The bubble may be said to be enclosed in a 'liquid skin[1].' Therefore to attach this bubble to any substance, this liquid skin must first be penetrated or broken. As seen from above, this requires some force.

As shown above, the force of chemical affinity is not sufficient to overcome this surface tension. So then, it could hardly be expected that a mere adhesive force would be greater than this surface tension. Therefore, to attach gas to solids in a liquid, it is first necessary to dissolve the gas in the liquid and then expel it in a nascent state.

There are at present only three known ways of forcing a gas mechanically into solution so that it actually occupies the interstitial spaces of the liquid molecules: (1) beating it in with stirrers or paddles as is described, for instance, in the patent papers of the Minerals Separation Co., where propellers or centrifugal pumps are used; (2) dividing it into such minute portions that, by capillary force, it is actually taken into solution, as is done in a Callow cell; and (3) introducing it as a surface film surrounding a jet of fluid by means of surface tension, as is done by a method under process of patent.

There are also three methods of expelling dissolved gas from a liquid that are of vital interest to the matter in hand: (1) Super-saturation, so that the excess gas comes out of its own accord; (2) heating, which expels some of the gas by increasing its volume; and (3) reduction of pressure. The present Elmore machines work the pulp in a vacuum, taking advantage of the fact that "at constant temperature, the gas dissolved in a given volume of liquid varies directly as the pressure"—Henry's law.

Since it is easier to work in the open air than in a vacuum, flotation machines using the principle mentioned, of forcing more air into solution than the liquid can hold, are preferable. The second method mentioned, of expelling dissolved gas by heat, aids the super-saturation type of machine in two ways: (1) nascent gas is expelled from the liquid to be readily attached to solids for flotation; and (2) dissolved gas is expelled from the solids so that gas bubbles may be easily attached to them. Here lies the whole secret of flotation.

[1]A striking experiment to show these liquid films is as follows: To a beaker partly filled with a colorless oil, add a small quantity of permanganate solution. Blow air through a finely drawn-out glass tube into the permanganate solution now on the bottom of the beaker. Air bubbles enclosed in the colored liquid film rise through the oil and break at the surface, because of the expansive force of the gas. The colored water drops back through the oil exactly in the same manner that a balloon, bursting, drops to the earth.

No solid can be floated unless it contains some dissolved gas. Why? For the reason, explained above, that the enveloping 'liquid skin' cannot be penetrated or broken. It was shown above that a gas bubble is surrounded by a film of liquid. A solid in a liquid is, in the same way, surrounded by a film of the liquid, for the same reason. Therefore, in a liquid, the molecules composing the film around a gas bubble would have no more attraction for those composing the film surrounding the solid than they would have for any molecules in the liquid itself. Hence the bubble would not attach itself to the solid. It is seen then that flotation has for a foundation a subject of which practically nothing is known—occlusion of gases.

It is self-evident that the same cause which tends to super-saturate a liquid with gas will also have the same tendency to super-saturate a solid contained therein. And also the same cause that tends to dispel from solution the dissolved gas will also tend to dispel the gas from a solid in this same liquid.[2] Therefore a solid in a liquid becomes a nucleus for the formation of bubbles. This is easily demonstrated by the formation of vapor bubbles when water is boiled.

The surcharging of a liquid with a gas, tends to surcharge any solid in this liquid—on account of diffusion. The adhesion of the gas for the solid, therefore, will tend to condense the gas on the surface of the solid. Sufficient condensation will collect enough molecules of the gas to form a bubble on the surface of the solid. The same effect, due to diffusion of gas in the opposite direction, will be produced by causing the gas to be expelled from either the liquid or a solid contained in this liquid. An example of this is the dumping of a cold ore into the hot solution of a flotation plant. Bubbles immediately tend to form on the ore particles, by reason of cohesive and adhesive forces, and have the tendency to be enlarged by the gas in solution in the liquid.

It is natural, therefore, to suppose that solids with high occlusive power for gases have a greater tendency to float. Here, then, is a cause of selective flotation. Hezekiah Bradford's patent No. 345,951 is the first to recognize this. Speaking of metallic particles, he states: "These floating particles appear to possess some peculiar qualities which repel water from their surfaces, especially when such particles are exposed, even momentarily, to atmospheric air[3]." Later this phenomenon caused trouble to, instead of benefiting, Hebron, who says in his patent No. 474,829, an interest in which is assigned to Carrie J. Everson: "I expel from such mineral and metal particles—the air and other gases—by producing as far as practical a vacuum—or, and preferably, by applying heat to the ore, thereby obtaining the desired expulsion of air and other gases."

Why then do minerals (here in these patent papers meaning solids containing metal), and especially sulphide minerals, occlude gases more readily than other solids? It is only necessary to look into the subject of ore deposition for the answer. Primary sulphide ores are changed near the surface to sulphates, carbonates, oxides, etc.; in other words, chemical affinity assists sulphides in absorbing oxygen or carbon dioxide. Hebron and others discovered, by the aid of the microscope, that most mineral particles to be saved by concentration have larger pores and surfaces of larger extent than equal sized 'gangue' particles. This gives a greater chance for gas occlusion, which is another cause of selective flotation.

There is practically no adhesive force existing between oil or fatty substances and water. As a general rule, an oil is but slightly soluble in water or water in oil. Therefore water will not adhere to a surface wetted with oil or oil will not adhere to a surface wetted with water. Also an oil, due to its property of capillary attraction, has that power of entering solids. Therefore, due to larger surfaces and pores, most metals and sulphides are capable of absorbing oil so that sufficient oil can be attached for agglomeration and flotation. This selective flotation, as mentioned above, is not now worth considering, because so large a quantity of oil is necessary. A small quantity of oil then cannot create selective flotation.

Mickle's experiments[4] showed that none of the minerals tried hot, cold, or with reduced pressure floated on oil under any of the conditions where floating would take place on water. This was to be expected, since the specific gravity of oil is less.

What then is the potent factor for selective flotation? It is the ability to vary the "angle of hysteresis[5]." It has been seen from the above that solids occlude gas which can be expelled from them. If this gas be expelled from them when they are in a liquid at a time when gas is expelled from the liquid, they become the nuclei for the formation of gas bubbles which will float them under certain conditions. Now, therefore, if it be possible in an ore mixture to drive out a considerable portion of the gas from all the particles, there will be insufficient remaining in the 'gangue' to float it while the mineral containing more gas will float to the surface. It has been found, for instance, that sulphuric acid in very small quantity added to water will decrease the angle of hysteresis to that point where quartz and similar 'gangue' will sink, while that of the metallic particles remains practically unchanged.

Since an acid in very minute quantity will produce this effect, it is not due to rise in temperature or reduction in pressure, which would drive out the occluded gas. This must be caused then by no ordinary phenom-

[2]"As in the case of liquids, we would expect that the amount of gas adhering to the surface or absorbed in the pores of a solid would vary with the nature of both of the solid and of the gas, with the extent of the surface, with the fineness of the pores and lastly with the temperature, becoming less as the temperature rose." Josiah P. Cooke, Jr. 'Chemical Physics.'

[3]He describes a traveling belt with one end in water to take advantage of this fact. This antedates, and is the same principle as, the Macquisten tubes.

[4]Proceedings of the Royal Society of Victoria. Vol. 23. Part 2 of 1911.

[5]Transactions Institution of Mining and Metallurgy, 1912, Presidential Address by H. L. Sulman.

enon. The only way that an acid can act in this manner is in the capacity of an electrolyte especially when diluted to its dissociation point. That is, complete ionization exists. Yet with this extreme dilution, gas is expelled from a solid contained therein. In other words, equilibrium does not exist. Why? It is on account of these ions of the electrolyte which cause this displacement of equilibrium between the solution and the gas dissolved in the solids within this solution. This then resolves itself into a simple case of osmotic pressure. The surface of the solid is the septum. The ions of the electrolyte enter the solid while those of the gas leave. Since the carrying solution is saturated with gas already, bubbles form; and this action continues until the eutectic point is reached. So far an acid (sulphuric on account of its cheapness) has been used as the electrolyte, because it produces such a great change in the angle of hysteresis.

In the future, as more is learned concerning flotation, the finer and more delicate manipulation will be better understood, permitting an alkaline electrolyte to be commonly used. This will allow of the selective action for mineral particles other than sulphides so that, for instance, cerussite or malachite can be separated readily from gypsum, quartz, etc. This is not to be confused with Horwood's "differential" or "preferential" process, whereby the surfaces of some sulphide minerals are oxidized by roasting to prevent them floating with another sulphide in a mixed sulphide ore.

While, as stated above, the fundamental requisites are the manufacture of 'life-preservers' and the attachment of these to the mineral particles, it is still necessary to rescue these particles. Bubbles, on coming to the surface of a liquid, burst if not protected, and the attached mineral particle sinks. Why do they burst? (1) Relief of pressure, so that the contained gas expanding exerts more pressure on the liquid film, (2) adhesive force of contained gas for the atmosphere, or (3) evaporation of the film causes this bursting. The greater the supersaturation, the greater the interior gas-pressure of the bubbles, so that they in reality explode. This is the case with bubbles in a glass of soda-water, for instance. How can this be prevented? The small boy will prevent it by coating the bubbles with soap—that is, by toughening the liquid film. This then is the secret of "the froth-forming material" so frequently mentioned in the various patent papers of the Minerals Separation company. Why is an oil the most useful substance with which to do this?

It has been shown above that metallic particles are readily coated with oil. Therefore, an oil may not only toughen the bubbles but a cohesive force is exerted on the oil-coated metallic particles. Besides an envelope to hold the gas, an aeronaut uses a net to strengthen his balloon, so that when the pressure is relieved by the higher atmosphere it will not burst. This same effect is obtained in froth-flotation. In the same way that particles form around drops of water on a dusty floor and prevent the globule from breaking, small particles form a network around the large bubbles. This is due not only to the force of cohesion of the oil on one particle for that on another, but the force of cohesion existing between the particles themselves. Thus a froth is formed of bubbles that do not readily break.

It is a well-known fact that water has the greatest surface tension of all liquids under ordinary conditions, except mercury. It is therefore a safe assumption that dilution with another liquid will decrease the surface tension. The tendency to float is decreased. With reduced surface tension bubbles burst more readily. From this it is easily seen that surface tension is decreased exceedingly by the use of a volatile liquid. Alcohol evaporating from a substance held near a bubble will diffuse sufficiently to readily dilute the surface film and quickly burst it. Mineral particles floated when, for instance, amygdaloidal or globulous eucalyptus oil is used will dance on the surface of the liquid, being apparently attracted and repelled until evaporation has progressed sufficiently to equalize the surface tension not only of the liquid but of the bubbles as well.

Water then is the natural and universal medium for all flotation machines and air the necessary adjunct. The air may be in the pores of the mineral particles and as films around them, so that they are not easily wetted, in which case the machine may take some such form as a Macquisten tube or Henry E. Wood type—a purely surface-tension effect into which enters nothing but water and air. The meniscus of the water buoys up the metallic particles surrounded with an air film that prevents them being wetted. The force of gravity is less than that of surface tension, so the particles float. If the particles be surrounded by a water-film, the cohesion of the molecules of this film for those of the body of water neutralizes the surface tension, and gravity sinks the particles. Or again, minute bubbles may be attached to metallic particles that necessarily contain occluded gas. A thin film of oil may enclose or contain the particles and their attached bubbles. With sufficient displacement the particles will rise to the surface and form what may be termed a DeBavay float. Or, lastly, the bubbles may be large and have the mineral particles attached to them, as well as being attached to each other. This is the so-called froth flotation.

Concentration at the Tonopah-Belmont mill is 0.67% by weight, and 11.5% in extraction of silver and gold. An analysis of the concentrate is as follows:

S	31.6	Mn	1.1
Insoluble	30.6	Cu	0.6
Fe	29.8	As	1.6
Pb	1.3	Al_2O_3	0.42
Zn	0.6	Undetermined	1.57
CaO	0.8		
		Total	100.00

In the last financial year this product assayed 446.05 oz. silver and 2.368 oz. gold per ton.

Brass is a copper-zinc alloy containing over 50% copper. When a third metal, such as tin, is added, the mixture is then called 'tin-brass.'

Regulations for Metal Mines

A publication of considerable interest to the metal-mining districts of the United States has just been issued by the Bureau of Mines, under the title, 'Rules and Regulations for Metal Mines.' It is to be known as Bulletin 75 of the Bureau of Mines, the authors are W. R. Ingalls, J. Parke Channing, James Douglas, James R. Finlay, and John Hays Hammond. This committee was originally appointed at a meeting of the American Mining Congress at Denver, Colorado, in November, 1906, and its object was the drafting of a modern law governing quarrying and metalliferous mining which could be recommended to the several States for adoption, in the hope that the passage of such a uniform law by the mining States would tend to lower the number of fatal and serious accidents.

When the committee took up its work, it found that Colorado, Missouri, Montana, and New York were the only states that had enacted mining laws of broad scope applicable to other than coal mines. California, Arizona, Idaho, Kansas, Michigan, Minnesota, Nevada, New Mexico, North Carolina, Oregon, South Dakota, Tennessee, Utah, Washington, and Wyoming, were found to have statutes pertaining to metalliferous mining, but with few and incomplete safety provisions.

This committee of the American Mining Congress did considerable work along this line and made a number of reports. In April, 1911, Joseph A. Holmes, Director of the Bureau of Mines, invited the committee to serve as a committee of that bureau with the idea of preparing a final draft of a law and this was accepted.

Starting with a composite of existing laws, the committee by successive stages endeavored to work out a general law that would embody the best mining thought of the day, be in accord with approved modern mining practices, and yet at the same time be effective and practical in operation, and not merely a collection of rules and regulations to be disregarded or enforced at will.

The committee in discussing its report says: "We have found that a great deal of interest and attention among mine operators has been awakened by our advocacy of improved means for promoting safety in mining. However, we are under no illusion that our recommendations will be immediately and generally adopted. We consider our work to be especially of educational character rather than anything else. It will be useful in three main ways, we think, as follows:

1. As a basis for State legislation.
2. As a basis for private systems of inspection.
3. As a collection of simple rules for the guidance of everybody engaged in mining.

"Since the publication of our first report several States have adopted new mining laws and amended their old ones. In this connection our code has served some purpose; for example, in the drafting of the laws that now stand on the books of the States of Nevada and Arizona. We do not expect that any State will at once adopt all of our recommendations, especially those that are essentially of legal character. We offer them as what we think ought to be and hope some day will be.

"Since our first publication, furthermore, most of the mining companies of consequence have adopted inspection systems or have at least framed codes of safety rules, which have been based to a large extent on our code, notably so in the case of the Cleveland-Cliffs Iron Co. This tendency, in fact, has become one of the most important phases in the national movement for 'Safety First.' This is the gratifying consummation that we had in mind. Unquestionably, also, the widespread adoption of State laws providing compensation for injured workmen has helped the safety movement by making accident prevention worth while.

"We consider, however, that the chief usefulness of the code of rules that we have formulated will be to small operators, who frequently engage in unsafe practices without knowing that they are unsafe or without thinking about the matter at all. There is a reasonable hope that our report will be of educational value to all mining operators.

"The act that we have drafted may be regarded from two angles—from the legal and from the technical. With respect to the latter we have had in mind the conditions and practice of mining existing and prevailing in the several parts of the United States. In our treatment of the matter from the legal standpoint, in which we have had the advice of good lawyers, we have refused to clothe the inspector of mines with the optional powers that are given to him under the laws of many of the British colonies, and, also, we have refused to convey to him the sweeping power that is given to health inspectors in some of our own States.

"The code of mining rules that has been finally drafted by the committee is the co-ordination of the experiences, opinions, and suggestions of a great many men who have assisted the committee in an advisory capacity and as directly employed aids. The former have included many engineers actively engaged in practice, members of professional societies, and members of the bar; the latter have included members of the regular staff of the Bureau of Mines and of the personal staffs of members of the committee. The committee has sought to obtain many points of view and to summarize many experiences. The draft that has been prepared is not offered as the last word upon this subject. There are many phases of this subject with which the committee has been unable to deal thoroughly. Thus the committee confesses its inability to formulate at the present time adequate rules covering the important subject of ventilation of mines. Similarly there are many practices in open-cut mining, by steam-shovels, etc., regarding which the committee has felt unable to formulate rules. We feel, however, that the rules so far as prescribed may advantageously be applied to open mining whether it be simple quarrying or the extraction of metalliferous mineral, as well as to underground mining."

Ore Dressing on the Mother Lode

By E. S. PETTIS*

An article by M. W. von Bernewitz in your issue of January 3, 1914, fully describes the metallurgical practice along the California Mother Lode. He speaks of a general impression that ore treatment in this region is sadly behind the times, though he found the contrary to be true at the time of his visit there. A. H. Martin mentions the fact that "California metallurgists have been most conservative in adopting methods developed by operators in other fields." We hear from many sources that modern ore-dressing methods are not to be seen on the Lode in contrast with the improved schemes adopted elsewhere. This may have been true formerly, but it does not hold good today.

An engineer visiting Amador county will learn that premature precipitation occurring during treatment, but is also due to the fact that this particular variety of slate is naturally the refractory part of the ore and the gold is not readily soluble in cyanide solution.

The ores from different mines vary in character, of course; this is perhaps not so noticeable in their appearance as in their amenability to treatment. It is most evident in the cyanidation of the concentrate. In some cases as much as 95% of the gold may be extracted by direct treatment and fine grinding, and in other cases less than 75%. A 90% extraction is claimed at a recently constructed mill, and large-scale tests indicate that a high extraction can be obtained by careful size reduction, amalgamation, and concentration, without re-

A TYPICAL MILL ON THE MOTHER LODE.

W. E. Darrow has been most progressive in the treatment of slime by concentration. The Darrow-Hambric slime concentrator produces a low-grade concentrate amenable to cyanidation with a fair extraction. This seems to be the best method available for treating the slime produced from the slaty ores of this district, and I venture to say that this will remain the prevailing scheme of treating the so-called float slime for some time to come. The oil-flotation process may possibly be adopted in the larger mills, but this is doubtful, and direct cyanidation has so far not shown satisfactory results, giving about 50% extraction. The poor extraction by ordinary methods of cyanidation is not entirely due to the reaction commonly called re-precipitation, which is sorting to fine grinding or canvas-plant treatment. However, the average extraction in the various mills is about 85%.

I remember, when passing through Salt Lake in 1907, the criticisms aimed at the wholesale use of stamps in Nevada and California, and we (on the outside) are still talking more determinedly than ever about "the passing of the stamp-mill." Here I make special mention of a new stamp-mill in the Grass Valley district where cyanidation follows amalgamation and concentration. It seems that the noise of the stamp-battery will still remain with us, much to the dissatisfaction of operators, though we all admit that the roar of the stamp-mill from a distance is music to the ear and a proclamation of productiveness.

*Metallurgist, Mill Valley, California.

We must bear in mind that the stamp-battery, essentially a quartz mill, has been performing its duty on the Lode and elsewhere as a gold-saving device as well as a crushing machine, and no other device seems to be equal to the double duty. The uniqueness of the stamp is that you can make it do the work of the rock-crusher and of the fine-grinding machine combined. This is typical of California practice, with amalgamation in the mortar as the main argument. Perhaps this is the cause of associating amalgamation with ore-dressing rather than with metallurgy.

The Plymouth mill was the first to deviate from old practice, although this mill cannot be taken as the model for the new metallurgy; still it is a step in the right direction and promises excellent results. In his article on this subject Mr. Caetani* has not emphasized emphatically enough the value of stage-crushing and classification of the general run of Mother Lode ores. I need only refer to the persistence of the canvas plant. I believe his contention correct regarding the danger of enriching the colloids by excessive sliming of mineral through fine-grinding in one operation, as with the stamp-battery. Surface tension of the water plays an important part in the floating of excessively ground sulphides and the oily nature of the slaty slime increases the float losses. An exceedingly dilute pulp is required to separate the fine sulphides by settling. This is the reason for the development of the automatic Darrow deck tables.

There is one advantage of classification that is not often mentioned, but appeals to the practical operator of the small mill and is not evident in the older California mill. That is, the concentrator department should be operated separately from the crushing department; and the classifier seems to perform this function, inasmuch as the classifier and dewaterer practically insure the non-interference with good concentration by variation of feed and water ratio in the crushing department. When the battery-man can use all the water he wishes without interfering with good concentration, the stamp-mill can be brought to its maximum crushing efficiency. It has been my experience in operating concentrators on unclassified material that the irregular ratio of feed to water continually occurring in the stamp-mill, due mainly to the occasional avalanche of fine ore from the mill-bin into the stamp-mortar, materially interferes with good concentration. The real value of classifiers and dewaterers is not for better concentration alone, but for the purpose of enabling the use of more water in the stamp-battery to lessen the excessive sliming of free mineral, the use of a finer screen, and the maintaining of the economical tonnage. Where dewatering is desirable, a classifier is advisable at 20-mesh to separate the sand and slime for slime-thickening and better extraction by economical concentration. Thickening-cones are considered necessary at nearly all up-to-date plants to precede slime concentration, but you see no such apparatus on the Lode, even where the total extraction is obtained by ore-dressing methods.

It might be interesting to recall an extreme case in the treatment of an ore once considered refractory. The following results were obtained by actual mill-runs at a 20-stamp mill in Tuolumne county. The plant has been converted into a direct-cyaniding and all-sliming plant, and has given excellent results on quartz ore.

MILL-RUN No. 1

The stamps dropped 105 per minute; 4½-in. drop; 6-in. discharge; crushing through 60-mesh; water ratio, 5:1; inclination of plates, 2 in. per foot; stamp-duty, 1.5 tons.

Twenty 850-lb. stamps, seven 4-ft. vanners, and canvas-plant; unclassified concentration; 1205 tons.

Ore heading $10.40

	%
Amalgamation	40
Vanner concentration	9
Canvas concentration	13
Total	62

MILL-RUN No. 2

Stamps dropped 83 per minute; 7-in. drop; 7-in. discharge; 60-mesh; water-ratio, 10:1; grade of plates, 1⅜ in. per foot; stamp-duty, 1.6 tons.

Sizing:

	%
— 60 + 100-mesh	30
+ 150 "	10
+ 200 "	8
— 200 "	52

Classification into three products: Coarse sand, fine sand, and slime, 445 tons.

*Ore heading $6.49

	%
Amalgamation	37.0
Vanner concentration	15.2
Canvas concentration	12.3
Total	64.5

*The increased extraction was obtained from ore 40% less in value.

MILL-RUN No. 3

Stamps dropped 85 per minute; 7 to 8-in. drop; 8-in. discharge; 60-mesh screen; water-ratio, 8:1; grade of plates, 1½ in. per foot; stamp-duty, 1.8 tons; feeding finer ore to battery, 532 tons.

*Ore heading $8.69

	%
Amalgamation	42.5
Vanner concentration	19.1
Canvas concentration	8.2
Total	69.8

*20% lower-grade heading, concentrate of same value ($50 per ton) in all runs.

I was told at one of the plants where vanners are in use that unless careful plate-amalgamation preceded concentration, some of the fine amalgamable gold was lost, passing from the vanners with the tailing. I failed to observe as careful plate-amalgamation on the Lode as elsewhere, referring to mills in which the grade of plates is set at an inclination of 1¼ to 1½ in. per foot.

The California practice is to get the free gold as soon as possible, and in changing to the two-stage crushing method we are confronted with the problem of amalgam-

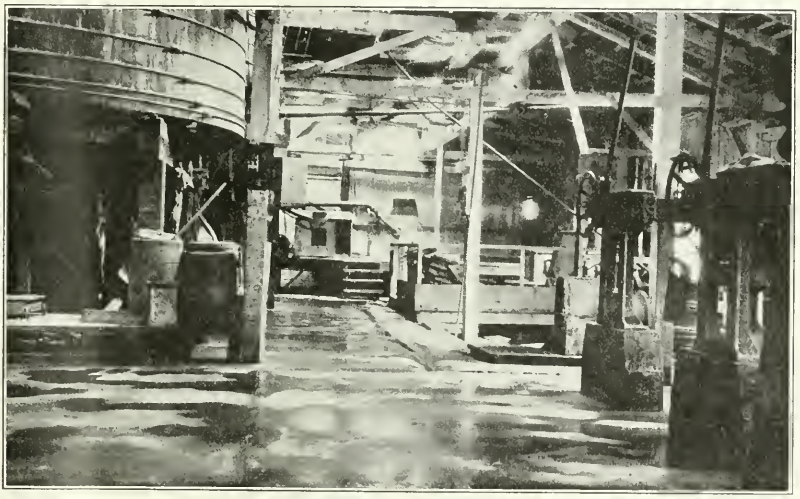
*"The Plymouth Mill," by Gelasio Caetani, MINING AND SCIENTIFIC PRESS, October 31, 1914.

ating the coarse gold as successfully as has been accomplished in the mortar of the stamp-battery.

In South Africa, plate amalgamation in the tube-mill circuit is advisable for extracting the coarse gold, but cyanidation follows, whereas in a concentrating plant the concentrator saves what the plate cannot, and in some cases the reverse.

In adopting the two-stage crushing of modern practice, why not eliminate this unnecessary amalgamation of coarse gold entirely before concentration, as has been done in many mills elsewhere, and employ the apparatus now used in amalgamating the concentrated material as it comes from the table? If it is true in any particular case that the concentrators lose fine gold that can be amalgamated, I believe in amalgamating a thin pulp after concentration and classification, passing the fine over plates of low inclination, obtaining the benefits of classification in plate-amalgamation as is the better practice in concentration.

Probably the most modern mill on the Mother Lode is at the Original Amador mine. This mill was described in the PRESS of June 19. The excess water used in stamping and classifying is clarified in a large thickening-tank, with subsequent concentration of the thickened slime on Deister tables. Cyanidation of the total concentrate is another addition, completing the process of local treatment. The Deister tables used throughout the plant are operated at high efficiency. As the concentrate can be treated locally, an increased extraction is possible by producing a so-called sandy concentrate. The most noticeable departure from ordinary Mother Lode practice is the elimination of extensive plate amalgamation before and after fine grinding. Some amalgamation of the coarse gold is attempted in the Hardinge amalgamator, and on short sluice-plates following. No provision was made for returning an oversize from the pebble-mills, as they have sufficient capacity to reduce the ore with one passage through the mill. I am told that the capacity of the whole plant is to be increased, and the pebble-mills operated with a return of an oversize. In this event there will be less sliming of the sulphides and less enriching of the slime, which is concentrated in a thickened condition. An equal extraction with increased tonnage will be the result. The pebble-mill, reducing to 40 or 60-mesh, seems to work at higher efficiency with some very coarse material in the circuit, and in feeding a pebble-mill product from a stamp-battery, instead of using, say, an 8-mesh screen with a low discharge to maintain a given tonnage, it is better to feed as uniform a product as possible. Therefore a 6-mesh screen and higher mortar-discharge is preferable, using water in proper quantity.



INTERIOR OF A CYANIDE PLANT.

[Mr. Pettis neglects to mention an essential feature of this mill, namely that the overflow from the concentrate-classifier is pumped to one 18-ft. diam. by 12-ft. deep treatment-vat, equipped with the Trent cyaniding apparatus. This vat, with a dilution of 70%, has a capacity of 30 tons of concentrate; and, when starting to grind a charge, the vat is filled with barren solution, the circulating pump started, and the valves set to operate as a thickener and replacer. Then the pulp from the classifier, having about 80% dilution, with about 50% of the gold dissolved during grinding, is pumped into a 12 by 12-in. box hung in the centre and submerged 3 ft.; and, while the charge is being ground and thickened in the bottom of the treatment-vat, the clear overflow, with a large proportion of the dissolved gold, overflows and goes to the sump-vat, which has a filter-bottom. After the charge is ground, and previous to agitation, about 50% of the solution in the treatment-vat is replaced with barren solution, and the valves on the vat changed to operate as an agitator. This is continued for six or

eight hours, after which all the recoverable gold is in solution. The valves are then changed on the treatment-vat so as to operate as a thickener and replacer, and about 10% in excess of the solution in the vat is replaced with barren solution, after which 20 tons of wash-water, carrying about 2 lb. alkalinity per ton is added, and the charge allowed to settle into the wash-water. The solution above the pulp is then decanted into the sump-vat and the pulp sluiced to waste.—Editor.]

In the testing-plant I have found that crushing in the stamp-battery to 8-mesh, screening through 20-mesh, and concentrating the 20-mesh undersize (representing about 45% by weight of the original ore), an extraction of 50%, or more, of the total content can be obtained from the general average of the Mother Lode ores. No appreciable amount of free mineral remains on 20-mesh.

Experimenting with a somewhat refractory ore containing perhaps a less proportion of slate than the average, about 10% slime was produced in stamping through 8-mesh. In this particular instance the ore was crushed through 8-mesh and concentrated, re-ground in the closed circuit of a continuous pebble-mill to 40-mesh, plate amalgamated, and concentrated unclassified. The ore assayed $4 per ton, and yielded 50% at the first 8-mesh concentration, 30% by plate-amalgamation of 8-mesh tailing re-ground to 40, and only 5% by final concentration. The slime portion, 10% of original feed from 8-mesh crushing was thickened and concentrated on a Deister table with the following results:

	Percentage by weight.	Assay.		Content, %
Heading	100	$3.20		100
Tailing	...	2.65		79.7
Concentrate	1.85	35.20		20.3
Extraction	...	0.65	or	20.3

Extraction per Original Feed

	Percentage by weight.	Assay.		Content, %
Heading	10.1	$3.20		7.95
Tailing	9.02	2.65		6.40
Concentrate	0.185	35.20		1.55
Extraction	....	0.065	or	1.55

The gold extraction from this first slime product by direct concentration is low even when exercising great care, and very little of the gold can be saved when endeavoring to concentrate on the same table with 20-mesh sand and an excess of water. The first slime produced by coarse stamping or wet crushing with balls should be eliminated from the bulk of sand and fine material before finer grinding, and treated separately. It is difficult to settle this slime to any degree of density, and the oily nature of the float slime (carbonaceous or otherwise), has a tendency to float the fine mineral when mixed with the re-ground sand. This is what happens in the single-stage crushing-apparatus. Apparently 60-mesh is the proper size for the second grinding for economical concentration or amalgamation of these ores, and to study the most efficient method of ore-dressing applicable to Mother Lode ores, one need only refer to modern methods used elsewhere in concentrating plants.

I understand that investigations are being made for a possible method of treating Mother Lode ores, especially by cyanidation, by the U. S. Bureau of Mines. This will probably prove to be a double-treatment method, on account of the precipitation of gold during dissolution. Still, when an extraction of 85 to 95% may be obtained by careful concentration and amalgamation from $3 to $6 ores at a milling cost of from 30 to 50c. per ton, it seems that energy should be exercised in developing more mines and economical crushing-plants for handling large tonnages.

Iron ore mined in the United States in 1914 was as follows, in long tons, according to the U. S. Geological Survey:

State	1914	1913
Minnesota	21,946,901	38,658,793
Michigan	10,796,200	12,841,093
Alabama	4,838,959	5,215,740
Wisconsin	886,512	1,018,272
New York	785,377	1,459,628
Pennsylvania	406,326	489,056
Virginia	378,520	483,843
Wyoming	366,962	537,111
New Jersey	350,135	325,305
Tennessee	330,214	370,002
New Mexico	81,980	164,085
Georgia	67,722	155,236
North Carolina	57,667	69,235
Missouri	37,544	39,354
Kentucky	21,400	3,400
Utah	(*)	14,690
Colorado	10,464	(*)
Connecticut	9,149	(*)
Massachusetts	7,600	(*)
West Virginia	6,530	7,808
Maryland	6,369	(*)
Ohio	5,138	7,849
Montana	(*)	2,475
California	1,282	2,092
Other States†	40,800	115,370
	41,439,761	61,980,437

*Included in Other States.

†In 1913: Colorado, Connecticut, Idaho, Maryland, Massachusetts, Mississippi, Nevada, and Texas. In 1914: Idaho, Mississippi, Montana, Nevada, and Utah.

Pig-iron production was 23,332,244 tons, a decrease of 24.65%. The quantity marketed was worth $71,905,079.

Graphite. In his work, entitled 'Les Richesses Minérales de Madagascar' (published in 1912 by Dunod et Pinat, Paris), D. Levat states that on the island of Madagascar, the graphitic gneisses form a belt of 40 kilometres radius surrounding Tananarive. The natives work exclusively on the decomposed outcrops which are easily handled with pick and shovel without explosives. This decomposed material contains approximately 10% graphite in disseminated scales, but owing to their crude methods it takes 20 tons of it to produce one ton of graphite.

Lime production of the United States in 1914 amounted to 3,380,928 short tons, worth $13,247,676. There were 954 plants operated, a decrease of 79.

Geology as an Aid to Tropical Engineering

By WARREN D. SMITH*

Introduction. The purpose of the present paper is to discuss, first, the general geologic processes as they are found at work in the Tropics, contrasting their effects with the same processes in the Temperate regions of the earth, and second, to cite some examples showing their practical bearing upon the engineering problems arising in those regions.

From many years of contact with engineers and their problems, particularly in the case of Tropical countries, I know that often all too little attention is paid by the engineer to the fundamental considerations upon which geology alone is capable of throwing light. This is due frequently to a deficiency of and lack of breadth of training. How is it to be overcome? It is hardly to be expected that the engineer-student will be able to put any more geology into his already crowded courses. That, however, is not necessary, for all that is desired is that he realize his limitations and the importance of the bearing of geology upon his work and the need for expert advice. Some engineers in the Philippines with whom I have had the pleasure of working showed that they appreciated this fully. Others did not, and as a consequence they have left monuments to their lack of insight.

Previous to our experience in the Philippines and Panama, we Americans had had no especial contact with the Tropics and consequently many of our engineering data were found untrustworthy when applied to wholly new and unusual conditions. An especially good example may be cited in the location of our highways and railroads. In the United States, we run a railroad line up one canyon over the pass and down the other side by way of another canyon. This has been tried in the Philippines, notably in the Benguet road; the result is that this road will have to be abandoned because of excessive cost of maintenance. In the Tropics, during high water there is room for but one thing in a valley and that is the stream which occupies it; such a feat of engineering as that which has made the Royal Gorge and the Denver & Rio Grande railroad famous is absolutely out of the question.

There is one cardinal rule to be laid down at the outset, namely, take nothing for granted, investigate each problem separately. Handbooks and set formulae are worse than useless; they are dangerous.

I wish to compliment Professors Ries and Watson for giving us their admirable work on 'Engineering Geology.' This book, good as it is, however, does not help us much in the special field we are considering; therefore, I offer this contribution to the subject. There is one other book on this same general subject, by Sorsbie, which I am frank to say was a disappointment to me as it contains little that is either new or specific.

The general topics considered in the following paper have already been broached by me in an article contributed to the Proceedings of the Philippine Society of Engineers and I am indebted to members of that society for many data and much inspiration. The United States may well be proud of her young engineers in the Philippines. Their work may have been less spectacular than the digging of the Panama Canal but political, social, and racial factors have made the Philippine job no less difficult.

Geological Agents. The three most important geological agents are:

1. Diastrophism.
2. Vulcanism.
3. Gradation.
   - Weathering.
   - Transportation.
   - Corrasion.
   - Corrosion.

1. Diastrophism. This denotes up-and-down movements in the crust of the earth. Such movements are negligible apparently in the older and more stable parts of the earth, but, even there, they manifest themselves as earthquakes. In the newer parts of the earth and particularly along continental borders they are of great magnitude and importance. As it happens, many of those places are in the Tropics. This is true of both Panama and the Philippines. At least once and perhaps twice before, the barrier of the Isthmus of Panama, which has cost so much in life, labor, and money to cut through, has been overcome by the intermingling waters of the Atlantic and the Pacific and it is not at all impossible that future diastrophic activity will make all our labor useless. However, these movements are so slow as to be almost negligible in any one generation. Only the geodesist finds that he has to readjust some of his calculations.

2. Vulcanism.

As the Philippine archipelago is a part of the so-called Circle of Fire that girts the Pacific Ocean, we naturally expect the vulcanism to be of such magnitude that the engineers would have to be continually anxious. Nevertheless, except for those regions in the immediate vicinity of active volcanoes, little damage has ever been recorded from this cause. The most marked effects were those noted in 1911 resulting from the explosive eruption of the Taal volcano, situated about 25 miles due south of Manila. Had there been a large city the size of Kingston, Jamaica, for example, situated on the shores

*Past-president of the Philippine Society of Engineers; head of the Department of Geology, University of Oregon.

of Lake Bombon much damage might have been done. The town of Lemery, only a few miles distant, suffered to the extent that an old church made of volcanic tuff was badly disfigured and a triangular section of land, crossed by one of the Government's new highways, dropped about three feet, allowing the tide to come inland for perhaps a half mile. The length of damaged road amounted to about two miles. These effects were due directly to earthquakes and indirectly to the volcano. Although 498 distinct shocks were recorded in Manila, at the time of the eruption practically no damage was noted. The claims of a certain American firm, with a patent type of concrete construction, that none of their buildings had suffered any damage at the time were strictly correct, for no buildings in Manila revealed any weakness.

Another instance in which vulcanism did play an important part was that in which a section of road in one of the provinces was obliterated for a distance of two or three miles by a fall of bombs and a deluge of mud and ashes from the Mayon volcano in 1902.

3. Gradation.

This is the sum total of the wearing-down process—in many respects the dominant geological agency. If we analyze this process we find that the following agents are contributory: a. Weathering; b. Transportation; c. Corrosion; d. Corrasion. I would, however, make 'corrosion' a sub-heading under weathering, there being two factors involved in weathering, a mechanical deformation, and a chemical change, either of which may precede the other. Then once weathering, or, to use a very crude term defining it in part only, 'sleeking' has taken place, transportation comes in and does its work and then 'corrosion' or mechanical wear becomes operative, but not until there is movement.

Of course, these factors are operative in all countries and under nearly all conditions, but gradation probably proceeds at a maximum rate in the Tropics. Two reasons are given for this, namely, rainfall and temperature, or in one word, climate.

In the Philippines we have a mean annual rainfall of over 100 inches, with sometimes exceptional and almost unprecedented precipitation, notably 72 in. in 56 hours on July 29, 1911, at Baguio Observatory, P. I. This record is second only to that recorded at Simla, India.* At such times the streams leave their banks and spread out over the country in sheets of water. Needless to say, the amount of material then transported is almost incalculable. Furthermore we have another factor to consider, namely, the factor of velocity. Often this is not taken into consideration. When we stop to consider that doubling the velocity of a stream means increasing its transportation power 64 times, we realize what a power we are trying to combat. We shall return to this topic.

Once the tropical downpour of warm rain has stripped off the soil, weathering can and does strike deeper into the core of rocks beneath and however far we go underground in mine workings we find the rocks exhibiting incipient decomposition. I know this to be true from the examination of a great many thin sections of wall-rock from the deepest mines in the Archipelago. Undoubtedly the presence of organic acids, resulting from the decay of the rank tropical vegetation, hastens this decomposition. Of course, we have little or no frost, except on the highest mountains, but we do have wide ranges in temperature during the 24 hours and this adds to the disintegrating forces at work. And so all things considered, we have reason to think that gradation is the most potent of the geologic processes at work in the Tropics.

Special Problems. Road-building and maintenance. In the Tropics and particularly the Malay region, the seasons are sharply defined, one of practically no rain and one during which it rains in torrents. If we recall the rule that the carrying power of a stream varies as the sixth power of its velocity, we know at once we cannot take any chances with a tropical torrent. In regions of high relief we have four things to consider and we cannot neglect any one of them. They are:

1. Declivity or head.
2. Sudden increase of volume due to configuration of the valleys.
3. The angle of slope of valley-walls.
4. Material and structure of the valley-walls.

I have seen highways placed in valleys at such points that the road was continually menaced by the stream just below it and by the sliding of material from the slopes above. The stream is dangerous because of two things:

First; the sapping of the water itself.

Second; when the velocity is doubled it can carry particles of rock 64 times as large as before; and in time of freshets, boulders weighing tons are carried along, each one acting as a battering ram. No retaining-wall can be expected to, nor does, withstand this terrific bombardment.

Again, the composition of the country-rock, its structure, texture, and the state of weathering are of vital importance. If the weathering extends to a considerable depth, it will be an easy matter to start slides (witness the Culebra Cut at Panama), and if this weatthered material slides into the canyon below, a temporary and very dangerous dam results. When the dam breaks, and it soon must with the impounding of the torrent behind it, all will be swept before it. We have a remarkable example of this in the now famous Benguet road on the island of Luzon. The Bued river is a small stream, little more than a creek in the dry season; it flows from 5000 ft. elevation to the sea. The valley-walls are V-shaped, the average slope being probably as high as 35° or even 40°. The country-rock is a badly decomposed andesite for the most part with some tuff deposits, much jointed and with innumerable small faults, all loosened by many earthquakes. Here we have ideal conditions of instability, which were perfectly ap-

*[These rainfalls are remarkable, but are quite drowned by that of Cherrapongee, in Assam, where an annual deluge of 900 inches is recorded.—Editor.]

parent to geologists, yet as far as I know, no geologist was consulted by the engineers until it was too late. The inevitable happened. First, slides continued until the slopes reached the angle of repose; then dams followed, impounding the water to a great depth; next, the dam broke and search parties were out looking for the road, buried under sixty feet of debris. Now after many years and spending much money, the road is to be abandoned. And so they are going back to the ridges, following the example of the Spaniards.

On the question of the engineering technique involved in the construction of these roads, I would venture to lay emphasis on the necessity for drainage—keep the foundation of your road drained. You may say that this is nothing new, that every engineer knows that, but the application in America where the rainfall is merely a light summer-shower as compared with the tropical downpour is a different problem. As to how it should be drained, that is not within my province as a geologist.

Maintenance on a road constructed of poor materials is one thing while that on a road wherein a wise selection of metal has been the rule is an entirely different thing. Right here a geologist with his microscope is a necessity. Petrography, once despised as an academic study, is now indispensable to the scientific road-builder. There is a pathology of rock just as there is a pathology of animal tissue. The microscope will reveal at once, and at little expence, whether or not the minerals composing the rock are sound, whether there is incipient decomposition, or a far-gone state of decay. It will show also the fabric or texture of the rock. If the rock has an ophitic texture, that is, the minerals interlaced to make up a sort of mat, then we may look for toughness. Why one rock splinters and another does not, or why one crumbles rapidly into a powder, is at once made clear.

At one time I collected rock-specimens from a number of places along one of the principal Philippine highways and among the samples was one that yielded a briquet which when placed in the De Laval cementation machine refused to break under 2000 blows, whereas an ordinary basalt briquet yielded at the 22nd blow. A thin section of the fresh rock was made and examination showed that there was a small amount of secondary calcite in the rock, an alteration-product of the lime-bearing silicates; it was this that furnished the excellent binding qualities. The rock was a diorite just beginning to decompose without having gone so far as to reveal this condition to the naked eye. This rock, with its holocrystalline texture and just the right amount of calcite, would make a most excellent road-metal because it had two essential qualities, namely, toughness and high cementation quality. Of course, the objection of high cost will be raised at once; but no matter how the finances stand, there is never any excuse for putting worthless and unsuitable rock on a road. My plan is this, let the geologist recommend one or more kinds of material and then let the engineer consider which he can afford to use.

I am glad to state that that is the way the Philippine Government is doing things, for the advice of the geologist is always considered nowadays by the engineers of the Bureau of Public Works. The Bureau of Science maintains a road-testing laboratory.

A VALLEY IN THE HIGHLANDS OF LUZON.

Artesian Water. The principles governing the concentration and movement of ground-water are now well understood, but, at the risk of repetition, I shall make a few general statements.

First: Although we do not see it, the sea of underground water is almost as extensive and in some ways more important than the ocean. All the rocks, varying in degree of saturation, contain water down to a limiting depth. Some of this water is found in the large trunk-channels, joints, and faults, but a great deal of it is in the form of hygroscopic water, that is, water held in the pores of the rock by capillary attraction. Some rocks, like the dense volcanic flows and quartzites, contain practically no water. Other rocks, like the limestone formations, have subterranean rivers passing through them, but the sandstones and chalks are the most important in this respect. A true sandstone consists of grains of quartz compacted together. The more nearly spherical these grains are, the more continuous are the openings. In such an arrangement of spherical grains there is always a continuous passage through the mass. Along this passage the water travels. Some sandstones have as much as 35% of pore space.

An English geologist, H. B. Woodward, makes the statement that the quantity of water held in the chalk of England by capillary attraction is tremendous. One square mile of dry upper chalk, one yard in thickness, contains nearly 3,500,000 gallons of water, and when saturated holds 200,000,000 gallons.

The loose volcanic tuff formations of the Philippines are also great water-carrying formations. This water is generally circulating slowly in the small openings, but when the water reaches a fissure, naturally the circulation is rapid.

Let us consider the best condition for artesian water. As the deep-seated igneous rocks are usually dense and have but little pore space, and as the fractures of this formation have no regularity, it can be seen at once that this is a poor formation in which to seek water. Water may be traveling along a fissure in this formation, and the well-digger may pechance strike this fissure, but usually the chances are slim. There is no excuse for locating a well in such a formation. A limestone formation is also poor, for while it is cavernous and contains underground streams, it is a pure piece of luck when one of these is struck. The best conditions are found in the sandstone, volcanic tuffs, and beds of unconsolidated ash. Having found the formation, we must next consider some features in the structure of the region. The ideal condition is where the sediments form a syncline (basin) with the water-bearing stratum outcropping at a higher point than the site of the well and where there is an impervious layer of clay or shale just above the water-bearing stratum. The effect of a fault on the water circulation would be to divert the flow to springs at the outcrop, but the effect of an igneous intrusion would be to block the water circulation. All of these things must be examined, if possible, previous to the digging of the well.

It is incredible that even at this late day water should be sought with a divining rod, yet in 1907 an attempt was made to find artesian water with a divining rod in the city of Zamboanga (Mindanao). Water was not found, and an examination of the geology of the country showed that very little chance existed of a supply being tapped within a reasonable depth. In spite of one or two apparently plausible features about the divining rod, the use of this device may be classed with other pseudo-scientific operations such as palmistry and astrology. Besides this case of the Zamboanga well, there is one on record in California where a man spent about $25,000 trying to get a well in a semi-arid district. He never did get water, and a geological examination of the country revealed the fact that a fault in the neighborhood precluded utterly the possibility of water being found in that part of the formation in which he was drilling.

Three or four years ago at Olongapo, Luzon, a well was drilled on the naval reservation, and when I visited the place I examined the cuttings in the drill and found the material to be diorite, which is the basal formation of the island and contains very little water, having no regular continuous water-passages. The well-digger drilled here for 22 months. No water was found, and in the end he lost all his tools in the hole. As the driller was paid by the foot, he, of course, did not have to pay the bill. On the island of Guimaras the same thing has recently been done. In another part of the Islands a well was dug and the water was found to be brackish. An examination was made of the locality, and it was found that the stratum which had been tapped outcropped a short distance away in salt water.

The Bureau of Public Works, I believe, has paid more regard to the geology of the country than any other engineering organization here; and, so far as its wells have been dug in the Manila central plain, good results have been obtained. But I wish to emphasize this fact, that in spite of all the practical experience of a well-driller, there are many more things to be taken into consideration than simply those that pertain to digging the well. The instances in all parts of the world of unwarrantable waste of money are so numerous as to prove that the practical well-driller is not the one to locate a well—he is often thoroughly unpractical. At the present time a special expedition of five geologists and two topographers is at work in Patagonia,† loaned by the United States to the Argentine republic, for the purpose of choosing favorable artesian-well sites for the Government.

The question of health enters largely into the location of wells. It is important to know the structure of the country in order that one may know the direction of drainage and whether or not pollution of the underground streams does or does not exist.

†[We are informed that this expedition found no artesian basins possible; hence, geology was of negative value. But, with American resourcefulness, the expedition turned its attention to topographical and hydraulic engineering; after much hard labor, a supply of water was found in a river that had not been considered previously because it was supposed to flow at too low an altitude.—Editor.]

I am told that in certain parts of the Hawaiian islands water has been found by sinking through the overlying formation, largely consisting of lava, to the ash-beds that lie buried below. The water here is ponded in this loose formation by the coral reef bordering many parts of the islands. The same conditions, no doubt, could be found in many parts of the Philippines.

It is time that there should be some good wells in crystalline rocks, but, as Ries and Watson bring out in their diagrams, the chances of striking a joint or fault carrying water is much less in these compact rocks than in a formation every void of which is saturated with water.

Dams and Reservoirs. The geological conditions affording the best sites for dams and reservoirs have also been covered by Ries and Watson. With reference to this phase of the subject I wish to state that a geological examination of a district and several years of stream-gauging is not only desirable but imperative in the Tropics. I could cite many examples of how these works should not be located, but two or three will suffice. The city reservoir at Montalban was made in a limestone gorge. The limestone is full of caverns and the reservoir failed to hold water until it was lined, bottom and sides, with cement. If the dam had been placed at the upper end of the gorge the reservoir would have had a natural clay bottom.

The destruction of the Tarlac (Luzon) dam probably could not have been foreseen, but if a few more data concerning annual precipitation and stream-discharge had been secured the trouble might have been averted. The Agno river when under full head is a terrible engine of destruction. A dam was built in the hills back of Cebu making use of an apparently substantial formation for abutments and spillway. Drilling was recommended by the geologist who examined it; but no, that would be too expensive. The abutments held in a terrific storm that ensued, but the spillway, which was too small, forced the water to eat its way down through a decomposed formation which had a hard shell on the outside, so that the dam was useless.

From my observations in the Philippines, I should be inclined to say *never* build a reservoir in the Tropics. If water is needed use diversion weirs in streams or else artesian wells.

Coal Mining. I had intended not to touch on any phase of the application of geology to mining engineering in this article for the reason that the connection between the two is so generally recognized. There is just one point that should not be overlooked here, and it is one that has given more or less trouble to those who would work coal seams in the Far-Eastern Tropics. It has been my experience throughout many years of examination of coal prospects and mines in the Tropics that the persistence of a given seam of coal is always a matter of conjecture. They often thin or 'peter out' just when you are counting on a good working thickness. I have long sought for a geological reason for this and have at last worked out these tentative conclusions:

THE RESULT OF TORRENTIAL WASH, IN THE PHILIPPINES.

1. We have great rainfall over most of Malaya today. There is every reason to suppose that this has been the case throughout most of the Tertiary period, which is the age of the tropical Malayan coal.

2. The great deluging downpours of rain mean coarse sedimentation and frequent interruptions to the quiet accumulation of vegetal matter from which we are to hope for a future coal deposit. We do find that the character of the underlying and overlying beds in the neighborhood of these uncertain coal-beds is very variable, coarse and fine strata alternate with no great thickness to any one stratum. So my advice to the engineer or geologist who is sent out to examine a coal deposit in any part

of the Tropics is this: examine carefully the nature of the enclosing strata, the character of the grains, size, and arrangement, and take nothing for granted, put down test-holes or drill everywhere in the field, and, better still, drive on your coal.

Geodesy. Over fifty years ago there appeared in the Transactions of the Royal Society several articles by the learned Bishop of Calcutta, a mathematician and physicist of no mean repute, relating to the perplexities then confronting the surveyors in control of the great Topographic Survey of India. This, one of the greatest of surveys, is still in progress. The problem that confronted them was how to account and allow for a very noticeable and very important discrepancy between the trigonometrically located stations and those ascertained by astronomical determinations. To cut the matter short, the trouble was found to be in the deflection of the plumb-bob due to the mass of the Himalaya mountains.

In the course of the coast survey of the Philippine islands, it has been found that there are frequently large discrepancies between the location of the trigonometrical stations and the astronomical stations. This has amounted, in some places, to 30 or 40 seconds of arc, which may mean a matter of half a mile or more on the surface of the earth. How to adjust this has been a matter of some difficulty. The great piles of volcanic rock constituting the Zambales mountains are adequate to explain the discrepancies at some of the stations on the west coast of Luzon. But, at Olongapo, it was found that the plumb-line instead of being deflected to the east was deflected to the west, though the main mass of the Zambales mountains lies to the east. An examination made by me several years ago of the Cinco Picos range, which lies to the west of Olongapo, revealed the fact that these mountains are made up of one of the densest rocks known, the rock called peridotite. This rock has a density of over 3, whereas the main mass of the rock in Zambales has a density only of about 2.5. Therefore, apparently, this discrepancy is explained by our knowledge of the geological features of the two regions.

Seismology. Earthquakes are not confined to the Tropics. Nevertheless, the regions of greatest seismic disturbance are either within the Tropics or not many degrees removed. I do not know that there is any connection between these facts. It happens that the newer (geologically) parts of the earth are for the most part within this zone. In view of the great engineering works built at Panama, in the Hawaiian islands, the Philippines, and elsewhere, it is of importance to understand the principles controlling earthquake phenomena.

In an investigation conducted for many years by Father Masó of the Philippine Weather Bureau and myself, we found that of the great number of earthquakes in the Philippines from 1599 to 1909, only a comparatively small number could be traced to volcanoes, and that of the 25 seismic districts in the Philippine islands, only five are near or include active or dormant volcanoes, and the two regions of greatest seismicity had no volcanoes at all.

The damage done at San Francisco by earthquakes, the catastrophes of Messina and Avezzano, and the lesser disasters that have overtaken the Philippines from time to time, all force us to pull our heads out of the sand and look facts squarely in the face. Of course, a great deal can be done to minimize these destructive occurrences by proper construction.

There are two things we must do to cope with earthquakes; in the future we shall in all probability do much more—perhaps predict, as is indicated by Perrett's work.

First, build structures completely tied together, whether of bamboo (the best type), wood, or concrete. My preference is for sand-lime brick securely tied to a steel frame.

Second, we must map the geology so as to show all formations, contact lines, and faults.

We may be able some day, if we study these things under the guidance of Montessus de Balore and Perrett, to see a people living in comparative security enjoying unafraid the fruits of husbandry in an earthquake region.

Physiographic Control of Economic Development. My last topic is quite different from any of those I have already discussed and does not permit of definite statement nor of exact proof. I shall attempt to show by the citation of three cases how a knowledge of the geologic and physiographic conditions would be beneficial in practical matters, aside from the more obvious applications to mining.

The island of Cebu in the Philippine group is long, narrow, and mountainous. It has an interrupted strip of coastal plan on which practically the entire population of the island may be found. The people are poor and live largely on and by the sea. There is no productive 'hinterland' or back country. Paralleling and for the most part within a few yards of the sea is a first-class macadam highway. With these conditions confronting them a railroad company constructs a third (steel) highway for the most part within a few yards of the first two. Had it not been for the Government guarantee of 40%, this venture would have been a great loss to the investors. The railway never had a chance of success and the guarantee is a conspicuous example of lack of business acumen on the part of the Government.

My second case is that of the now famous Benguet road, already mentioned. I have tried to show how a highway can run up a canyon in the Philippines and be permanent. Now the change of location for this artery of travel leaves a big section of the country stranded, but at the same time will tend to develop the other section through which the road will in the future run. In this particular case the coastal tract in the neighborhood of San Fernando de Union (west coast of Luzon) will receive a great impetus.

North of Lubig bay (about due west of Manila) there is no first-class typoon harbor on the coast of Luzon. This deficiency is reflected at once in the general character of the coast towns and cities all along this west and

north shore-line of Luzon. The same is true for a goodly portion of the east coast of the same island and again on the east coast of the great southern island of Mindanao.

I can give a practical example illustrating how this works out: The island Pollillo off the east coast of Luzon has some good coal seams—true bituminous coal—and there is a good harbor at Burdens on this island, but no harbor worthy of the mention anywhere near on the mainland (Luzon). Consequently scarcely any ships navigate these waters. Now we know pretty definitely from investigations made in Borneo that a coal mine in this part of the world must be able to sell most of its coal to passing ships in order to succeed. The coal cannot under existing conditions be shipped to Manila. So here we have the coal industry depending upon the amount of shipping on that coast and that in time dependent absolutely upon the nature of the coast and the population thereof, all of which go back to geologic and physiographic conditions. And so we see so-called practical business men making blunders like these because they refuse to consider as practical the advice of the scientific investigator.

The San Francisco Mint in August

Operations at this institution were interesting on account of the English and Japanese gold coins, and Chinese bars received, and the minting of $50 octagonal and round Exposition coins. The total gold received was worth $13,890,289.59, and 1,236,191.81 oz. silver valued at $600,330.82. The special coins amounted to $100,050, and others $115,350 (half dollars and one-cent pieces); also ₱5000 of bronze one-centavo pieces for the Philippines. Coin, bullion, etc., on hand at the end of the month totaled $310,549,174.78.

The Baggaley method of converting blast-furnace flue-dust into a commercial product is accomplished by passing molten iron direct from a furnace, ladle, or mixer in an even stream through a small swirl-basin and thence through a funnel 33 in. long, which extends from the bottom of the basin. A steady stream of dry, screened flue-dust is fed into the centre of the swirl-basin by means of a pipe which has a refractory lip. The lip is submerged in the molten metal to prevent the escape of flue-dust into the air. It is claimed that 4000 lb. of molten iron and 1000 lb. of dust can be passed through the basin and funnel per minute. Any number of basins may be used. The coke and limestone and a large portion of the silica are burned out of the dust, making it possible to return the remaining metal to the blast-furnace, where it can be re-melted at a minimum cost. With a 33-in. funnel, 500 lb. of dust may be treated per ton of iron.

Tin-plate (sheet-iron coated with tin) and terne-plate (sheet-iron coated with an alloy of tin and lead) consume only 20% of the total output of tin. Tin-plate ordinarily contains 2 to 3% of its weight in tin. While terne-plate contains about half this amount.

Mining in China

A prominent United States official who passed through San Francisco a few days ago stated that opportunities for the investment of capital in Chinese mines were excellent. China undoubtedly has rich mines that are not being properly worked, but the mining laws are such that no prudent foreigner will engage in mining. Mr. Loke Chow-Thye, a citizen of the Malay States, is quoted in the *Mining Journal* (London) as follows:

"I visited many mines and discussed numerous schemes with mine-owners and also Government officials, but after a year's work I find there are many obstacles in the way just now, and am returning home to the Straits Settlements a disappointed man. The chief difficulty is that the Chinese who obtain Government permits for mines seldom work the property to any extent, but use their permits to keep others out. If you inquire why they do not work on a larger scale, they invariably say that they are short of capital, but when you offer to provide capital it always occurs that when you get down to details you cannot get a reasonable offer. It seems to be an invariable belief of the mine-owners that because they have registered the property therefore the whole contents of the mines belong to them. They themselves cannot find capital to work it properly, but they expect you to find all the capital, take all the risks, and share half of the profits with them.

"If they have spent a few thousand taels in obtaining the Government permit and scratching the surface, they expect you to spend a few hundred thousands of taels on their property, and then, after taking all the risks, you might share half and half the profits. This attitude of the mine-owners has been brought about, I think, largely by the Government Mining Regulations, where (in Article IV) it is laid down that 'the shares taken up by foreign subjects shall not be allowed to exceed five-tenths of the whole share capital.' This would be all right if the Chinese mine-owner could raise one-half of the necessary capital, and agree to accept a reasonable number of shares for the property and the previous expenditure, but generally they want to receive half the shares in exchange for a control of the mine without putting up any capital themselves.

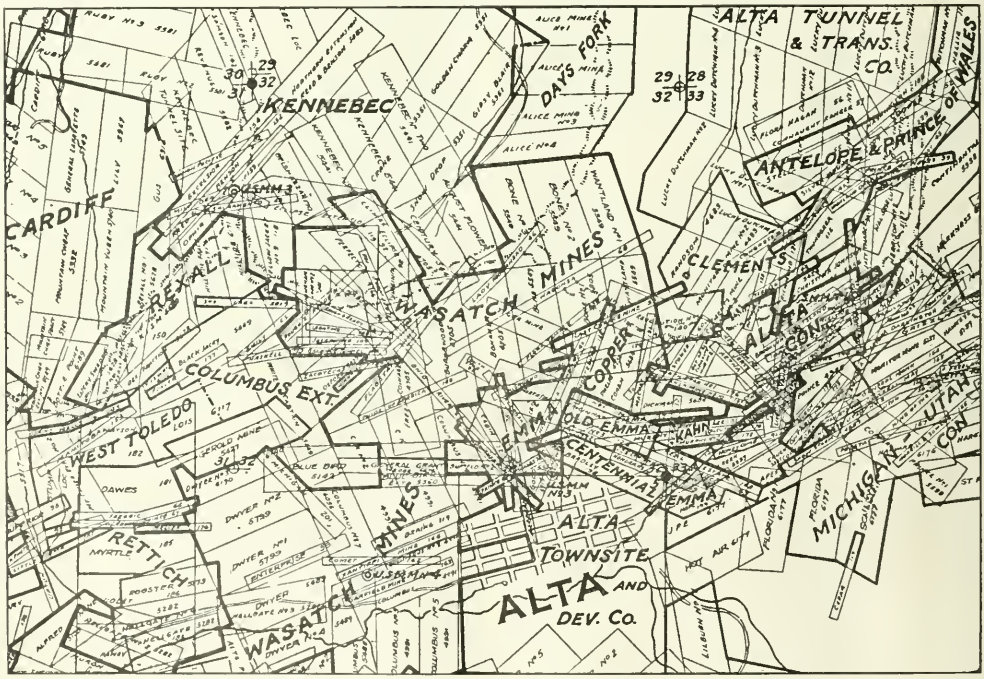
"This arrangement is not laid down in the Mining Regulations, but this is the way in which it is construed by the owners. Although a Chinese by birth I am a British subject, and therefore come under the heading of a 'foreigner' under these mining laws.

"Of course, another obstacle is the lack of company laws that would allow limited liability companies to be floated, as is so often done in the Straits under British law. If the Chinese understood from experience how to float companies and get capital subscribed they might be able to find their own capital, but there, alas! arises the question as to whether they could trust their capital in a purely Chinese company. The future of mining in China is undoubtedly great, but there is a long way to go before success is sufficient to invite capital."

Mining in Utah

By L. O. HOWARD

The fluctuations in the metal market come with such rapidity that forecasts in one month must be revised in the next. In my review of last month I referred to the effect of higher prices for lead in causing operators to speed-up production. Now this stimulus to maximum production has passed with the return of lead to normal and silver to so much below recent prices that the silver-lead producer is in a quandary. There has been no marked reduction in shipments from the silver-lead mines, and the search for zinc ore still goes on unabated. Two prominent phases of mining now attracting attention are the exploitation of old tailing-dumps and the continued speculation in stocks of the Alta-Cottonwood district.



MAP OF THE COTTONWOOD DISTRICT, UTAH. INCIDENTALLY, IT SHOWS THE EXTRAORDINARY CRISS-CROSSING OF CLAIMS DUE TO THE APEX LAW.

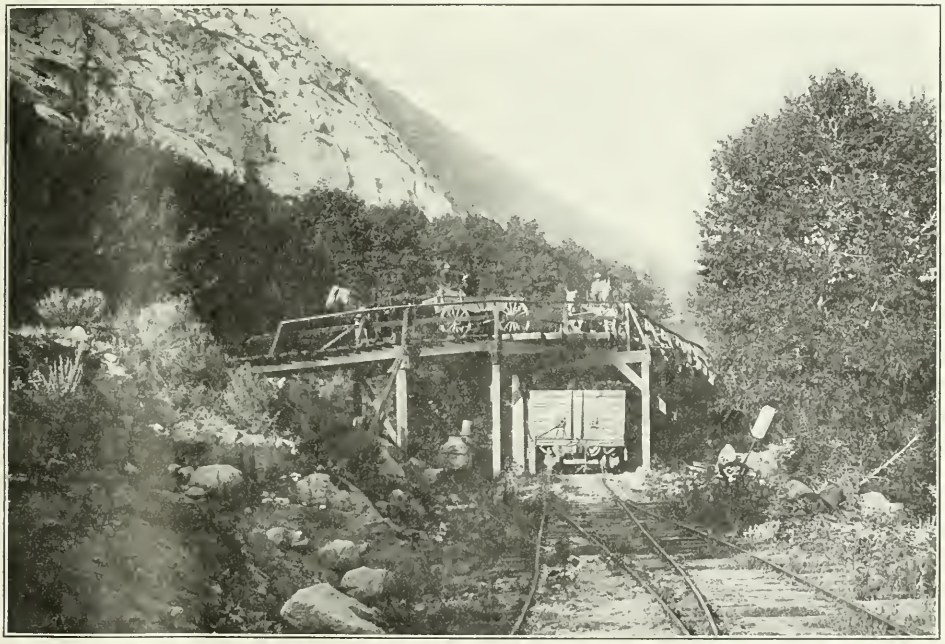
Aided by the high prices prevailing at the time the tailing projects were initiated, but owing their real stimulus to the increasing adaptation of flotation to diverse ores, three large mills are approaching completion. Mills ranging in capacity from a few tons to 500 tons per day are either at work or soon will be in reclaiming base-metal tailing. [One, on the Big Four at Atkinson, is the subject of an article to be published in our next issue.] Reference is made to operations of other mills, large and small, in the same district. One of the simplest of these small plants has only a jig and two tables. The tailing is shoveled from a platform to a jig with a fine screen, which rejects the coarse material and much of the worthless stuff, by combining the functions of a screen and a jig. The fine is drawn into the hutch and is then cleaned on two Wilfley tables, for the production of a zinc concentrate of excellent appearance. A little vertical steam-engine drives the plant; the whole of the equipment is exposed to the elements. I have also mentioned the use of flotation in the Broadwater mill, at Park City, for the recovery of the zinc.

In the southern part of the State at the Cactus mine, in Beaver county, further progress has been made in the use of flotation. The Broadwater mill depends on com-

bined concentration and flotation, whereas the Cactus plant will treat the tailing by flotation alone. There are several interesting features in connection with this plant, not the least being the content of the tailing, which is 0.8% copper. The mineral is principally chalcopyrite in a quartzite gangue, the reject from a wet-concentration mill using jigs, tables, and vanners. There is estimated to be 1,000,000 tons available for treatment. The mill has been designed to handle 500 tons per day. The tailing that passes a 6-mesh screen will be re-ground to 65-mesh in two Hardinge mills in closed circuit with two Dorr simplex classifiers. The 65-mesh product will be treated in a 12-cell Minerals Separation machine, for the production of a finished copper concentrate, a finished tailing, and a middling to be returned to the head of the machine with the feed. Tests indicate that the recovery will be close to 80%. It is expected that the plant will start operations early in October.

These tailing enterprises are being conducted by small groups of men who are using their own money. Vastly different are the majority of operations in the Alta-Cottonwood district. Much of the prominence of this district has been due to continuous boosting on the part of those interested in the stocks of companies owning ground there. The district, which is now divided into Big and Little Cottonwood, was one of the earliest to be opened in the West, and has an honorable record of production in the early days. At shallow depth water put an end to profitable operations in many properties, while in others the ore pinched. It is only recently that a serious effort has been made to prove ore in depth. There is a great deal of activity, for which some credit must, in all fairness, be given to those who have been behind the stock movement. While but three or four properties can be classified as mines, many of the others have prospective value, and will doubtless discover orebodies as work proceeds.

The country is a series of limestones, quartzites, and shales, dipping at 35° northeast, which is cut by two groups of fissures nearly at right angles. The northeast-southwest fissures give the best indications of ore. The formations are much broken by major and minor faulting of limited extent, so that exploration is rendered difficult. The geology of the district as a whole has never been satisfactorily deciphered. The ore is found in the fissures and at the contacts between different strata. No large orebodies, as compared to those found at Park City, for instance, are indicated as yet. Development expense is heavy and transportation facilities are not of the best. Silver, gold, copper, lead, and zinc, both oxidized and sulphide, have been found at varying depths in small amounts. Lead, silver, and copper predominate. The principal producer is the Cardiff, situated in the south fork of Big Cottonwood canyon. It is reported that shipments of oxidized silver-lead ore are now being made at the rate of 200 tons per day. The haul down the narrow-canyon roads, 28 miles to the sampling works in the Salt Lake valley, results in the



END OF WAGON-HAUL AT WASATCH, IN LITTLE COTTONWOOD CANYON. (Photo by Shiplers, Salt Lake City.)

employment of many men and teams and in greatly increased cost of operation, above what could be attained were an outlet to Little Cottonwood available. The ore is said to contain $35 in silver and lead. The present excellent appearance of this mine has been the excuse for boosting the district. At the beginning of the year stock sold at 6 cents per share, and went begging at that. Recently a nominal quotation of $5.10 per share was reached on the local exchange.

Only a few of the properties are equipped with power, but the Cardiff is to use power-drills as soon as a compressor can be had. The Maxfield, the most westerly property in the district, has pumping facilities and is endeavoring to unwater its workings, in order to gain depth below the canyon. Other properties at which work, mostly adits, is being done, are the Tar Baby, Carbonate, Price, Baker, American Con. Copper, Neva, Kennebec, Victor, Silver Moon, Cardiff Extension, Big Cottonwood Coalition, Alta Tunnel & Transportation.

On the Alta or Little Cottonwood side of the divide separating Big and Little Cottonwood creeks, the Michigan-Utah has a number of lessees at work, and is endeavoring to finance large operations. The South Hecla, Emma, and Michigan-Utah are among the important producers, and appear to have more ore than others on this side. Development work is being done by the West Toledo, Columbus Extension, Albion, Sells, Columbus Extension, and Wasateh mines. The Wasatch has a hydro-electric plant in the canyon and furnishes power for some of the others. Transportation is better on this side of the divide. The Michigan-Utah has an aerial tramway to Tanners Flat, 26,000 ft. long. From that point the ore is hauled three miles to Wasateh, the terminus of the railway. A 12-mile rail-haul brings the ore to the smelters in the valley. About 200 tons per day is now being shipped, my estimate being based on 100 tons for the South Hecla, 70 tons for the Michigan-Utah, and the rest miscellaneous shipments.

A large amount of money is being spent in exploratory work in this locality. This has been accompanied by wild speculation in the shares of some of the companies, the effect of which is not wholly beneficial. Most of the stocks are highly speculative, and a few cents per share would represent their intrinsic value. Some of them have been inflated to near the dollar mark, with no showing of ore to warrant it. There are bound to be many disappointments under such unfortunate conditions; these are likely to react to the detriment of the district. On August 24, two of the stocks fell from 80 and 87 cents to 30 and 44c., respectively, and are quoted but little higher at this writing. This happened with no change in conditions at the mines.

There is a report in the daily press that production of molybdenite was to begin from the Alta-Gladstone mine. Details are lacking.

The betterment in the copper situation is reflected in the report of the Utah Copper Co., for the second quarter. Comparing with the first quarter, the production of copper in concentrate was 40,799,825 pounds, against 26,415,995 lb. in the first quarter; ore treated was 2,215,159 tons, compared with 1,396,341; this is a new high record for the company. The grade of the ore treated fell off from 1.44% copper to 1.42%. Extraction was 64.85%. Cost of copper was reduced to 7.49c. from 8.19c. per pound.

During the high zinc market the mines of the Tintic district shipped 29% ore and received 5c. per pound at the railroad. This was not entirely satisfactory, but there was little choice. At the present time the differential is not so great, so that there is one source of happiness in the face of the declining market. At Saline activity is still pronounced. Twelve cars of zinc ore were shipped in August and further development by new interests is under way.

Among the lead mines the initial dividend of the Utah-Apex at Bingham is worthy of note. Much is expected from the operations of this company, which is now on a strong basis. Production is at the rate of 30,000,000 lb. per year at a cost of 3½c. per pound. Affairs of the Ohio Copper Co. are still involved, but the lessees are continuing production, and are treating 2000 tons per day.

At the lead smelters, production is maintained at the normal rate. The Garfield smelter is operating five coal-fired reverberatory furnaces and two blast-furnaces, treating about 2700 tons of copper ore daily, over half of which is concentrate from the Utah Copper Co. At the International smelter three reverberatory furnaces are at work on copper ore.

Rittinger's Law of Rock Crushing. In a paper to be presented at the September meeting of the American Institute of Mining Engineers, Arthur O. Gates states that his experiments confirm Rittinger's law, which is: "The work done in crushing is proportional to the surface exposed by the operation; or, better expressed for this purpose, the work done on a given mass of rock is proportional to the reciprocal of the diameter of the final product—assuming that all the mass has been reduced to one exact size, which is only theoretically possible." Rittinger's theory is the law of the *cracks*. It is well explained in an article by E. A. Hersam in the Mining and Scientific Press, an abstract of which is given in the third volume of Richards' 'Ore Dressing.' After the acceptance of the substantially correct theory of crushing, there must be recognition of the fact that rocks of varying characteristics are met in crushing operations, that these rocks offer different resistances to crushing, and that it is unfair to compare the operations of two crushing machines upon dissimilar ores (even if they look alike) until some values are given to the resistance or energy absorption of these rocks under crushing conditions. Probably these units will be determined practically by applying a definite amount of energy to a definite weight of the rock, all of a predetermined standard size. The work of determining these constants should be done thoroughly by competent hands. The conditions under which such constants should be determined are discussed in a paper by M. K. Rodgers.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Electrum is a silver-gold alloy that has been found in the National mine, Nevada. A slab of ore several inches thick and 3 by 6 ft. across yielded $70,000.

Calcite is the only gangue mineral found with the 'pocket' gold deposits of the Klamath mountains, California. The gold is later than the calcite and replaces it. It nowhere enters the calcite for any distance.

Hydraulics was defined by Olmstead in 1838 as "that branch of natural philosophy which treats of fluids in motion." It is a part of the science of hydrology, which investigates the properties and phenomena of water. Stream gauging is an important part of hydraulics.

Thermit-welding of cam-shafts at the Tonopah-Belmont mill cost $42.53 per shaft. There was 85 lb. of thermit used. The weld was turned down to the original size, and the shafts broke after 36 days' service. Another one was welded, but the boss of ½ in. high and 4 in. wide was left. This shaft is working well, the boss being in the middle bearing.

The increasing use of electric-blasting and of larger charges emphasizes the importance of watching the condition of all leading and connecting wires and blasting-machines to see that all are kept in good condition and that connections are well made. Avoid kinking wires, as this leads to cracks and breaks not easily detected through the insulation. Do not drag wires over the ground, as this scrapes off the insulation. Test the blasting-machine with a rheostat at regular intervals to see that it is working up to capacity. Test all circuits with the galvanometer before attempting to blast. These are simple time and money-saving precautions.

Human moraines are formed by the operations of dredges in the frozen North. The tailing heap blocks up and interrupts the course of the original stream, and produces a series of more or less stagnant pools in the loops it makes in its meanderings along the sides of the gully. If the latter is broad there may be two or three parallel embankments, with pools of muddy water between them, amid which the stream has to find its way as best it can. The mud that is washed out in the process lodges in these lagoons and buries the bases of the stony ridges. This curious effect of gold-dredging will last for centuries and it may puzzle some future geologist to account for its origin.

In setting up a new battery of five stamps at Skidoo, California, it was found advisable to use an old mortar, the ends of which had been cracked in a fire. The cracks were treated with 'Smooth-on' cement, and pieces of heavy strap-iron riveted over them. When the battery was started, the cracks were not tight, and water leaked under one of the post-shoes. The grouting was dissolved and pounded out, throwing the cam-shaft and stem-guides out of alignment. It was important to have the battery working again as soon as possible. To wait for new grouting to set would require too much time, so the cracks were gone over and made permanently tight. The battery-post with its shoe was raised to its proper height by means of chains and screw-jacks. The old grouting was then thoroughly scraped out and the shoe re-leveled with wedges. The space under the shoe was banked with wet sand and molten lead poured in. The result was excellent, only two days being lost. The work was done under the direction of L. W. Orynski.

Question and Answer. With two others I own three quartz claims on the Mother Lode in Mariposa county. Adjoining them is our mill-site. They were all located some years ago. During this summer we spent $700 or $800 on grading for the mill, putting in mortar-blocks, etc. This work was done not on the old mill-site, but outside of the side-line of one of the claims, on ground not located. Will you please tell me whether this work, under the circumstances stated, is assessment work, or will do as such, as little or no work has been done on the claims this year? And does the mining law permit us to have a second mill-site? The three claims are located consecutively from end-lines, and it is my understanding of the law, that a group of claims is entitled to one mill-site of five acres. We have such a mill-site, but it was inconvenient to use it. If the law does not permit us to make another location of mill-site so that we may take in the ground where we have made the improvements noted, in what way may we acquire legal possession of the ground? We do not wish to abandon the original mill-site.

If the claims were ours we would hesitate to allow their validity to rest on the performance of the work indicated, especially since it is outside of the boundaries of the claims. The Land Department has held that work on a mill does not benefit a quartz claim within the meaning of the mining statute requiring patent improvements. The courts have usually held that patent improvements are on the same basis as annual labor. However, the Courts are inclined to be more liberal with such improvements, and they would clearly allow grading for a mill to apply as an improvement on a claim if it were actually situated on the claim. Unless very strong reasons are presented, the Land Department does not favor the allowance of more than one mill-site, even when used in connection with a group of mining claims. On a good showing more than one mill-site claim has been allowed. Under the conditions presented, it would be advisable to make another location of a mill-site covering the ground on which the recent improvements have been placed and hold both mill-sites with the idea that if the Department would only grant patent to one that the least valuable one could then be abandoned.

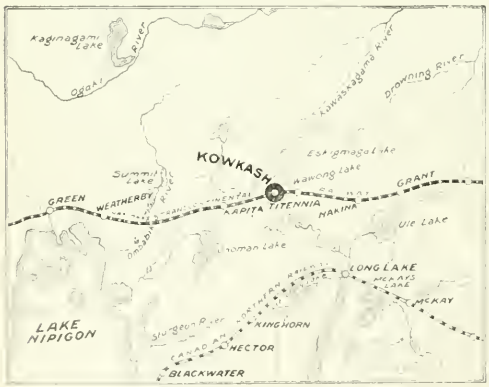
REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

TORONTO, ONTARIO

THE KOWKASH GOLDFIELD; HOW TO GET THERE AND PROSPECTS. —RICH ORE IN THE DOBIE MINE.—SUDBURY NICKEL DISTRICT.—POWER FOR PORCUPINE.—HOLLINGER MILL.—DOME MINE.—PORCUPINE PROSPECTS.

The greatest gold rush that has ever been witnessed in Northern Ontario has set in towards the new Kowkash field, about 300 miles west of Cochrane on the National Transcontinental railway. The first discovery was made by E. W. King Dodds on August 21, at a point on the Kowawkagashama river—mercifully abbreviated to Kowkash—some 20 miles north of Kowkash station from which point it is reached by canoe. Other prospectors quickly located claims, and many very rich specimens were brought to Cochrane, creating the greatest excitement in the mining centres of the north country. Many hundreds of prospectors from Cochrane, Haileybury, Porcupine, and Cobalt, have gone in, special trains



MAP SHOWING SITUATION OF KOWKASH, THE NEW GOLDFIELD.

being run to accommodate the gold-seekers, and the excitement has spread far and wide. As no staking had been done before the discovery last month, the chances for prospectors obtaining valuable claims are considerably better than in most gold rushes. Samples which have reached Toronto were stated by J. B. Tyrrell, one of the best authorities, as being exceptionally rich. They were taken from a vein of quartz and chloritic schist 6 in. wide. The country rock is diabase, which occurs freely for miles around. Basalt dikes occur as intrusives. The formation containing the shoots is paralleled by a broad belt of porphyry. Early prospectors had no difficulty in finding promising veins of quartz and schist on which to stake claims. One dike of quartz and chloritic schist 30 ft. wide, which is being stripped, is said to be similar to the best veins of the Hollinger, at Porcupine. Many men are now rushing in from distant points, including a number from the United States.

Some very rich ore has been found on the Dobie claims in Munro township, 50 miles east of Porcupine. These claims have been worked by the Dominion Reduction Co. for about two months, and until lately strict secrecy was maintained concerning results of development as the company was buying other claims in the neighborhood. A shaft has been sunk at an angle of 20° for 90 ft., and a large quantity of ore extracted, reported to assay 2000 oz. gold per ton. Two specimens of this ore, weighing together between 200 and 300 lb., are on view at the Canadian National Exhibition. It is reported that the company has a ton of ore of this grade sacked at the mine. The ore is found in bunches in a 2-ft. vein in diabase near its contact with basalt. This has been traced for several hundred feet, but the depth is not known. Officials of the Ontario Bureau of Mines, while not prepared to corroborate details as published, state that there is no question that an exceedingly rich discovery has been made. A large number of claims have been staked.

The discovery at the Dobie mine in Munro Township, has been quite eclipsed in public interest by the Kowkash stampede, but the first accounts of its importance appear to be fully borne out by later developments. The Dominion Reduction Co. has shipped gold valued at $50,000, extracted from 750 lb. of ore. It is estimated that the tailing contains $30,000 more. A shipment of $26,000 had been previously made from the same vein.

Nickel mining at Sudbury is very active. During August the Creighton mine produced over 73,000 tons. A new hoist is being installed at No. 2 shaft with a 5-ton skip, making the fifth hoist in operation at the mine. The other two mines of the Canadian Copper Co. also had large outputs. The Frood mine was closed down at the outbreak of the War, and about 40 houses moved to Creighton to accommodate the largely increased staff. An entire new set of fireproof shops are in course of construction, including electrical, carpenter, machine, and blacksmith-shop, and warehouses.——Some work is going on at the Vermilion mine, where the ore has been found to be difficult to treat, as in addition to nickel and copper, it contains platinum, palladium, and a little gold.

George T. Holloway, of London, the well-known metallurgist appointed chairman of the Ontario Nickel Commission, has arrived in Toronto, having spent some time before leaving England in gathering data dealing with the nickel market and its possibilities. He stated that a thorough examination of the Sudbury nickel industry would be made in order to prepare an estimate of the extent of the nickel deposits of Ontario, which would be followed by an inspection of the New Jersey refining plants.

The Northern Canada Power Co. has decided to extend its plant to supply Porcupine at a cost of about $1,000,000. Under normal conditions the present capacity of the plants at Waiwaiten and Sandy Falls is about 9500 hp., but when the water is low this is considerably lessened. The first extension will be at Sandy Falls, where a 2500-hp. unit will be installed. Afterwards the Waiwaiten plant will be increased. Dams will also be erected at various points in the watershed for the storage of water. The power requirements of the leading companies are likely to be greatly increased in the near future, as the Dome and Hollinger anticipate that within two or three years they will each need from 4000 to 5000 horse-power.

The Hollinger mill is now treating about 1500 tons of ore per day, and it is proposed to increase its capacity to 2000 tons. Ore from the crushing-plant will be screened, and the fine material sent direct to the tube-mills, the oversize only being crushed by stamps. Additional tube-mills may be required. The cyanide-plant is being extended, and eight settlers and two

agitators added to the continuous-decantation apparatus.—— At the Dome, horizontal drilling at the 700-ft. level has added to the ore reserves, the value of which is now estimated at over $17,000,000. The management has given extensive orders for machinery which will increase the milling capacity to 45,000 tons per month.

The satisfactory results of development by the larger Porcupine companies are causing a renewal of interest in prospects which have only been partly tested.——The Preston East Dome company will shortly start diamond-drilling on one of its claims adjacent to the Dome. Three of the directors have been inspecting the property to decide where drilling could be advantageously done.——The Temiskaming company, which has bought the minority interest in the North Dome, will also begin diamond-drilling this week.——Shareholders of the West Dome have ratified the proposal to re-organize the company. The new company capitalized at $3,000,000 will be known as the West Dome Consolidated, and shareholders will receive two shares of the new issue for each three of the old stock, leaving 1,000,000 to be sold to raise funds for development.

FAIRBANKS, ALASKA

Past, Present, and Future Aspects of Quartz Mining.—District Features.—Working Properties.—Mills.—Costs.

Quartz mining has been going on in a small way in Fairbanks district for over five years on small high-grade quartz veins containing free visible gold, and gold associated with sulphides. The predominant sulphides are stibnite, arsenopyrite, and pyrite, but galena and sphalerite are present in small quantities. Oxidized products from these sulphides are also present.

The conditions that prevailed have been almost prohibitive; but now that the Federal railroad between Seward and Fairbanks is under construction, and is expected to be completed within the next three years, the mining industry has taken new life, and new properties are being opened up.

The surface of the district is made up of ridges and valleys, but the relief is not great. The altitude of the ridges is about 2700 ft. above sea-level, and that of the flats about 700 feet.

Prospecting is rendered extremely difficult by reason of the bedrock, which is always schist, being covered by several feet of moss, 'muck,' and loose rock, most of which is permanently frozen. When 'float' quartz is once found, it can only be followed by sinking holes at intervals up the side of the mountain. When the vein is approximately located, it is necessary to dig trenches to bedrock and open the vein. After the 'pay-shoot' is found, the usual practice is to erect a windlass, and sink 50 or 100 ft. Then some ore is extracted and treated at a custom-mill.

Crites and Feldman, who own the only equipped and producing mine on Fairbanks creek, located their vein and shoot in this manner, and mined enough ore to pay for equipment. They have a 5-stamp mill and air-compressor with machine-drills, also a small saw-mill and all buildings to make the property complete.

The first ore mined yielded $130 per ton at a custom-mill. At present the adit-level is on 1000 ft. of a vein averaging about 6 in. wide. All stoping is being done above this level at present, and still farther up the hill two other veins have been exposed. One yielded 63 tons of $43 ore in doing 600 ft. of open-cut work on the vein, which was 6 in. wide. The other vein is 24 in. wide and returned $25 per ton. A shaft is now being sunk to prospect these veins at depth.

Nars, Anderson, and Gibbs, who own the extension of the Crites and Feldman vein, have a shaft down 100 ft., with 100 ft. of driving at the 600-ft. level, also some stoping on the vein, which was from 4 to 20 in. wide. This produced $27 per ton. The vein in both properties strikes northwest and dips southwest.

The McNeil and Huddleson mine has a shaft down 108 ft. on a vein striking north 60° west, and has 70 ft. of driving done on the 40-ft. level, and 70 ft. at 100 ft. Some stoping has been done on the vein, which is 8 to 40 in. wide. Ten tons of ore averaged $42 per ton at a mill. They have about 75 tons on the dump of approximately the same grade.

The Conners and Stevens mine, located near the head of Fairbanks creek, has the largest vein so far developed. It is from 7 to 10 ft. wide. From drifts at 60 ft. is produced 173 tons yielding $14.20 per ton. The vein strikes north and dips west, and is cut by several cross-veins striking east and west and dipping south. These veins vary in width from 6 to 18 in., milling from $25 to $60 per ton.

The Mispah claim, owned by A. Hess and associates, is just above the Conners and Stevens property. The vein strikes east and west and dips 75° south. The shaft is 120 ft. deep. On the 80-ft. level 100 ft. of driving has been done on a vein from 8 to 18 in. wide. About 40 tons of ore has been stoped that will assay about $40 per ton. One shipment of 14 tons from the surface on this shoot yielded $1160, or $83 per ton.

The Mispah vein crosses the Conners and Stevens property, and was located on the east end by L. M. Drury and others, who are sinking a shaft on a promising shoot 6 to 8 in. wide.

Foss and Farvain have a lease on the American Eagle claims No. 1 and 2, at the extreme head of Fairbanks creek. They have sunk a shaft 107 ft. on the ore-shoot, and driven a 500-ft. adit on the vein to cut it at greater depth. At present one stope is 80 ft. long varying in width from 32 to 44 in. From this 117 tons was extracted that averaged $14 per ton.

The mines in this immediate area have produced enough ore to justify the erection of a custom-mill. For some time a 5-ft. Huntington mill, at the head of Fairbanks creek, has been treating ore for $5 per ton; but when the large vein on the Conners and Stevens mine was found, Thomas Gilmore, who owns an interest in this property, decided to erect a 5-stamp mill to treat this ore, and also do some custom work. This mill will be completed in August. With two mills available for custom work it is expected that the Fairbanks Creek district will develop some mines of merit.

Owing to the fact that the veins are small as a rule, and usually badly faulted, they require close study and can only be worked at a profit by the owners themselves, or by good miners who are used to 'gophering,' and take them on a lease, usually paying 10% royalty.

Long adits to cut ore-shoots at depth are to be discouraged here, owing to the numerous faults and character of the formation. The erection of mills to treat ore developed by 100 ft. of driving or 50 ft. of a shaft should be stopped. This is emphasized by a score or more of idle plants in all parts of the district.

Among the other mines in the district that are being worked is the Homestake at the head of Wolf creek, a tributary of Clearly creek. It is worked under lease by O'Connors and Henderson, who have opened a rich shoot from 3 to 6 in. wide, striking east and dipping south about 45°. The ore is treated in the Rexall mill close by. These miners are making money where the company failed.

The Tanana quartz and hydraulic claims, controlled by Anthony Goessman, situated on Bedrock creek, a tributary of Cleary, have three veins opened. One is low-grade striking north and dipping west; the others are small and high-grade from 4 to 18 in. wide, striking east and dipping south, which have produced about 60 tons of ore averaging $75 per ton.

The Rhoads & Hall mine is on Bedrock creek, adjoining the Goessman. This mine has been working continually for the last five years under the personal supervision of L. B. Rhoads, the locator. The vein is from 8 to 18 in. wide, and yields about $40 per ton. To date the output is a little over $500,000. All the ore is stoped out above the 100-ft. level, and it will now be necessary to sink. As supplies are exceptionally high, wood

alone for steam power for 5-stamp mill and electric hoist and pump costing over $20,000 per year, the owners have decided to close-down and await the coming of the railroad, when the mine can again be worked at a good profit.

The Bradley mine, on Skoogy gulch, a tributary of Pedro creek, has a vein formation of altered schist and quartz about 90 ft. wide, which will assay between $3 and $5 per ton. With cheaper supplies, it may develop into a mine of large proportions. The same can be said of the Anderson and Birch mine on Granite gulch. Present conditions to not justify any development work.

As yet no depth has been reached in any of the mines, and none so far has shown large ore-shoots of good or even fair value, but there are many small veins and stringers of high grade that will pay good wages to the man who takes them out, and to him I can recommend the district.

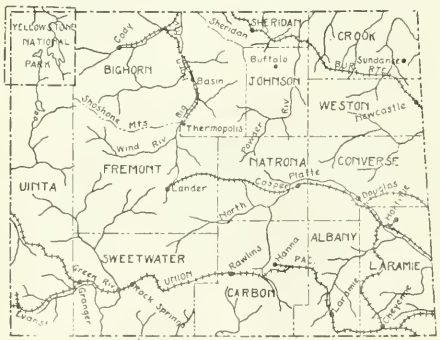
CHEYENNE, WYOMING

Sulphur. — Phosphate Plants. — Platinum. — Oilfields. — Potash.

The sulphur mines of Cody and Thermopolis are working full time. The crude material is used in making sulphuric acid, which is necessary in the manufacture of practically all the high explosives used in ammunition.

The phosphate plants along the Wyoming-Idaho boundary are again at work; their output practically all goes to Pacific Coast points.

The old Rambler mine at Holmes has again resumed operations. A concentrating plant has been installed, and high-grade platinum concentrate is being shipped. The new management has opened up a large body of ore, and it now seems certain that production will be continuous.



MAP OF WYOMING.

The pipe-line from the new Grass Creek oilfield has been completed to the C. B. & Q. railroad at Chatham. The oil is now being hauled to Casper for refining, but it is reported that the Midwest Oil Co. is to build a skimming plant at Chatham. The pipe-line was built by the Illinois Pipe Line Co., and the production of the field is controlled by the Midwest company, the Ohio Oil Co., the Fullerton Oil Co., and several local companies. There are in all about 30 producing wells. The six-inch pipe-line has proved to have a carrying capacity of 11,000 bbl. per day. This line is without pumps, having a drop of 1400 ft. in its length of 35 miles. Wildcat drilling has been almost at a standstill since the War began. Rigs are now being erected on favorable structures at two new points in the State, and it is confidently expected that these will result in new productive areas.

The high price of potash has intensified the interest in Wyoming potash prospects. It is hoped that a practical method of extracting potassium from leucite, (silicate of alumina and potash) has been evolved, and an experimental plant will be shortly built. A search for soluble potassium salts is being made among the numerous alkali lakes of the State. It is rumored that a potassium-sodium nitrate deposit has recently been discovered.

PLATTEVILLE, WISCONSIN

High Grade Takes Place of Low-Grade Product.—New Separating Plants.—Prices.—Lead.—Zinc Carbonate.

For genuine intensity of action, August stands out more prominently than any month so far recorded. A complete transition has been made from a low to a high-grade zinc-producing region. On account of the great and exacting demands for spelter, the large smelting concerns required high-grade concentrate only. Product containing under 58% zinc has practically no market at present. Dry methods of concentration, (roasting and electrostatic treatment of wet concentrate), enabled low-grade producers to make a product equal to requirements. Sufficient plants are now at work to treat the current heavy production, and to reduce the accumulations of about 10,000 tons at all points.

Of the many new separating-plants erected and building, one is deserving of special mention. This is being built next to the Champion mine at New Diggings, owned by the Wisconsin Zinc Co., a Maine corporation, and one of the subsidiaries of the American Lead & Zinc Smelting Co. The plant consists of one main building of steel and concrete, 100 by 140 ft., to house 10 Dings MM or medium, and H and HHH high-intensity machines. The complete mill will cost $60,000, and will be able to treat 150 tons of ore daily, and recover 500 to 600 tons of high-grade zinc concentrate per week. In the past year the Wisconsin Zinc Co. has developed zinc mines that will more than supply the ore required to operate the plant continuously. In additiou to this, the Company also took over the Joplin Separating Works at Galena, Illinois, owned by the Picher Lead Co. of St. Louis, after an idleness of three years. After repairs and overhauling this plant is in service.——The Fields Mining Co. of Shullsburg completed a plant at its mine.——The National Separating Works, producing one car of high-grade concentrate daily, enlarged its capacity. These plants however, are working on ores produced by tributary mines.

The building of custom plants, the one feature affording relief to small independent low-grade producers, was carried out to a satisfactory conclusion.——The Utt-Thorne Miuing Co. started a plant at Benton, placing a buyer in the field.——The Kistler-Stephens Co., of Platteville rehabilitated the Enterprise Zinc Separators, affording relief to nearly all low-grade producers in the Platteville district.——Some separating plants were started at a number of places, in many instances those that had been abandoned during the period of low prices, and which had existed for several years prior to August 1914. These too were consigned to the new work hoped for by low-grade operators, and the time is now almost at hand when very little product containing less than 58% zinc content will leave this field.

Prices for zinc concentrate during August were not so largely controlled by the metal quotations as is usual. Ore buyers were not active, bidding showing an utter absence of spirit, but still prices held up well. The decline in metal was met by one in ore that went as low as $55 per ton, basis of 60% metal, but long before spelter showed any signs of recovery, ore again began to climb and reached $86 per ton, showing real gains in favor of the miner. This price held strong at the close of the month, and the field was clear of high-grade material, the bins having been raked to supply the demand for finished product. The working off of the large reserve which had accumulated in the field is not such an easy matter as may appear, as the current production is rapidly increasing. A small car of

ore now brings from $2000 to $3000; a few years ago it realized less than half as much.

In the districts where the prospects of persistent ore deposits are better than others, every available foot of ground has been secured for its mineral rights. This was greatly accentuated by the passage of a new State law which removes the onerous taxation of orebodies yet to be proved. It is freely predicted by mining men that in another 60 days not a foot of ground will be available for leasing, unless transferred from parties first possessed.

Lead production in this field has depended for many years on the volume of wet concentration of zinc ores. Prices for pig lead experienced spells of depression during the month, receding to as low as 4.30c. at St. Louis, and regaining practically all lost ground, closing at 4.85c. The price of concentrate suffered, receding to $45 per ton from $60 paid in the early days of the month. Producers however, are not so much concerned now, since sphalerite is the ranking ore, and no sales were reported during the month. A reserve, variously estimated at from 2500 to 3000 tons of ore has accumulated, the Linden district holding about one-third of this amount alone.

Producers of crude iron pyrite contributed little raw ore during the month. Prices remained stationary, about $3.75 to $4 per ton, base of 50 units. The bulk of the sales reported came from separating plants where the recovery was made as by-product.

Producers of carbonate of zinc ore were again left entirely in the shade. The leading buying interest for the northern districts of this field, where this ore occurs, for years has been the New Jersey Zinc Co. Prior to 1914 the sales annually reached about 5000 tons, but so far this year a negligible quantity has been dressed for market, because this buying interest refused to pay the high prices demanded for an ore used exclusively in the manufacture of zinc oxide. Other buying interests that had the temerity on former occasions to invade this field were told by the New Jersey people to 'beat it,' and this they usually did. New buying interests crept in at the close of August, the Lanyon Zinc Co. securing several cars and paying fair prices. It appears certain now that the remaining months of the year will witness the development of sharp competition for this ore. Miners made large dumps of mill-feed through last winter's underground operations, which will now be quickly converted into a marketable commodity. Any outlet will be gladly welcomed by this class of miner, who has been practically starved out in the past year.

Deliveries of products in August were reported as follows:

Districts	Zinc pounds	Lead pounds	Pyrite pounds
Benton	10,542,000	.....	421,000
Cuba City	3,686,000	.....	1,746,960
Hazel Green	3,236,000	.....	.....
Livingston	2,210,000	.....	.....
Platteville	2,078,000	.....	.....
Mifflin	1,408,000	380,000	162,600
Linden	1,142,000	.....	.....
Shullsburg	544,000	.....	.....
Mineral Point	90,000	.....	.....
Highland	80,000	.....	.....
Potosi	52,000	.....	.....
Rewey	40,000	.....	.....
Total	25,108,000	380,000	2,330,560

The gross turn in of raw ore from all mines exceeded 24,000,000 lb. and net refined ores from separating plants and high-grade concentrates from mine to smelter direct, 15,000,000 pounds.

The most important work in the region was done in the south, where exploration, development, ore extraction, mill, power, and roasting-plant building showed great activity.

GOLDFIELD, NEVADA

Development in the Kewanas.—Inspection of District.—Jumbo Extension in August.—Sandstorm-Kendall.

The recent discovery of good ore in the Reorganized Kewanas property, at a depth of 840 ft., has aroused much interest, owing to the similarity of the ore and of conditions at the point of discovery to those in the Jumbo Extension mine, adjoining on the south. The shoot is in the shale-contact zone, and apparently in the main lode formation of the district, which has its apex on the Booth and Red Top. At this point the ground bears the same relation to the productive area in the Laguna and Red Top mines that the Jumbo Extension has to the Clermont. The stopes of the Clermont, on and above the 750-ft. level, have yielded the largest tonnage of high-grade ore of any in the district, and the Jumbo Extension has exposed a large tonnage of rich ore in the same lode, on its dip to the southeast and from the 850 to the 1000-ft. level. The lode, farther north, apexing on the Red Top, produced large quantities of rich ore to a depth of about 400 ft., where it passes, on its dip to the east, into the Laguna group of the Consolidated, and in the latter mine it has been worked and has produced good ore in large quantity, to a depth of over 750 ft. The object in exploring the Kewanas property and in sinking to the shale here was to find the point of contact between the lode and the shale, and this point has evidently been found. Copper is present in varying quantity, but a marked decrease in copper with increase in the gold-content has been noted as the drift progressed. A cross-cut is now being driven to the lode from a point in the main north drift, nearer the winze, from which all work is conducted.

F. L. Ransome, of the U. S. Geological Survey, has been in Goldfield for several days and has been making a comprehensive examination of mine workings in the district.

In the Jumbo Extension mine the contact ore-channel has been penetrated at a depth of 800 ft. This is the highest elevation in the mine where the contact ore has been found, and apparently marks the top of the hill or ridge of shale that rises above the fissure in which the best ore has been exposed. The secretary, Ben Gill, has released the following preliminary estimates of production and earnings of the company in August: ore mined, 3150 wet tons; gross value, $98,000; freight, treatment, and sampling, $28,000; mining, development, and administrative charges, $15,000; net realization, $55,000. This rate of production, yielding profits more than sufficient for a 10-c. quarterly dividend, will be maintained without difficulty, according to the management, and will be largely increased with the completion of the Velvet shaft.

Highly encouraging results are reported from the Atlanta exploratory work. At 1620 ft. the shoot so far is 150 ft. long, of $12 ore.

Work that is now being started at the Sandstorm-Kendall Consolidated property will attract attention during the next few weeks, as it involves cross-cutting and exploring the big lode at a depth of 700 ft. The winze from the east cross-cut on the 500-ft. level reached the 200-ft. point this week, having followed the steep dip of the lode, near the foot-wall. A station is being cut and a cross-cut will be driven to the hanging wall and then drifts will be put in. In the course of sinking many seams of good ore were exposed.

The Great Bend has completed all dead work and repairs to the old workings and has exposed the old faces on the 400-ft. level. The superintendent, Jack Campbell, will have the drifts extended on the main lode and a raise put up to prospect for ore found several years ago by lessees, in a winze below the 300-ft. level. The property is now in condition to make rapid progress with its development which has been planned by J. K. Turner, consulting engineer for the company. The surface plant is a duplicate of the equipment at the Velvet shaft of the Jumbo Extension. A new station pump will be installed shortly on the 400-ft. level.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

FAIRBANKS

Three and a half miles of placer ground on Greenstone Creek, near Ruby, has been purchased by the Yukon Gold Co. A 3.5-cu. ft. dredge will be constructed as soon as possible.

IDITAROD

(Special Correspondence.)—A Bucyrus drag-line excavator has been installed by F. G. Manley on his Willow Creek property. The machine has proved to be an efficient method for handling small dredging areas at a moderate cost for erection. This machine has a 1.5-cu. yd. bucket, 60-ft. boom, and 60-hp. boiler. The average daily capacity will exceed 1000 cu. yd. S. R. Fox is in charge of operations. He spent several years in California working a drag-line on a gravel mine, and expects to see this method successfully used in Alaska for excavating, where the floating dredge is not practical.

Willow Creek, July 29.

JUNEAU

July returns of the mines on Douglas island were as follows:

Results of operations.	Alaska Mexican.	Alaska Treadwell.	Alaska United.
Stamps working ...	120	240 and 300	120 and 150
Days	21.72*	*19.77 and 28.11	29.67 and 29.15
Ore crushed, tons...	14,714	68,684	42,994
Gold by amalgamation	$12,025	$61,825	$48,625
Gold from concentrates	9,749	69,698	40,364
Total realizable value	21,557	130,207	88,100
Operating charges ..	17,256	85,782	53,373
Construction	3,241	30,942	8,687
Net profit	1,059	13,483	26,040

*The short run was due to the break-down of the Central hoist, as mentioned previously.

The stock of broken ore in stopes decreased in each mine.

At the Ready Bullion the building for 30 additional stamps is finished. Stamps will probably start work on October 1. Four Deister tables are to be tried instead of 12 vanners.

SEWARD

At the new townsite of Anchorage, the railroad terminus, the Federal government at the end of August sold 749 lots for a total of $167,000. A camping area of 300 lots has been arranged by the Alaska Engineering Commission.

ARIZONA

COCHISE COUNTY

On Labor Day, September 6, the Southwestern Mine Safety Association held its second meet at Warren park, Bisbee. A large crowd assembled to witness the contests. The results were as follows:

First-aid (1) Ray Consolidated, two teams tied with 93.4. (2) Detroit, 91.5. (3) Calumet & Arizona, smelter team No. 10, 90.1. (4) Copper Queen, team No. 6, 87.2. (5) Old Dominion, team No. 8, 86.9. (6) Arizona Copper, 84.4. (7) Calumet & Arizona, mine team No. 7, 81.6. (8) Calumet & Arizona, mine team, 81.4. (9) Copper Queen, team No. 9, 78.6. And (10) Old Dominion, team No. 1, 75.6.

Mine-rescue (1) Calumet & Arizona, team No. 2, 97.8. (2) Detroit, 94.4. (3) Copper Queen, 92.6. And (4) Old Dominion, 88.2.

In the evening the Warren District Commercial Club gave a dinner to the teams taking part. There were 150 present, including the Association Secretary, Wallace McKeehan, J. C. Roberts of the U. S. Bureau of Mines safety headquarters at Denver, and leading officials of the Copper Queen and other companies.

In Bulletin 104 of the A. I. M. E., ventilation of the Copper Queen mine is described by Charles A. Mitke of Bisbee. The mine consists of seven divisions operated by mine shafts from 600 to 1700 ft. deep, all being downcast save the Lowell, an upcast. On the even numbered levels the workings are connected by motor-haulage drifts. The Uncle Sam, Southwest, and Czar ground has many connections to the surface, and is cool and ventilated by natural means. The Holbrook division is ventilated partly by natural and partly artificial means, and the Spray, Gardner, Lowell, and Sacramento areas entirely by mechanical means. The system used is described in detail.

GILA COUNTY

The Miami Copper Co. reports as follows for the half-year ended June 30, 1915:

Development, feet	8,295
Ore treated, tons (2.1816% copper).....	589,513
Concentrate produced, tons (40.63% copper).....	22,708
Extraction, per cent (now nearly 80%).....	68.16
Copper output, net, pounds.....	18,453,543
Cost of producing metal, cents per pound (now lower)	8.6889
Gross income	$2,841,188
Profit	1,296,225
Dividend	373,556
Surplus	922,668

A number of important improvements were made to the mill, while others are under way.

On August 26 the Iron Cap company's report stated that during July, 18 cars of ore, containing about 47 tons each, and assaying up to 10.87% copper and 10 oz. silver per ton were shipped. The profit was $14,389. Development continues satisfactory.

From the 250-ft. level of the Warrior mine daily shipments to the El Paso smelter amount to 110 tons of 6% copper ore.

CALIFORNIA

BUTTE COUNTY

At the Success drift-gravel mine of G. W. Rumble a 50-ft. shaft has found that about 24 in. of a lava-ash and clay bedrock contains gold nuggets and averages $30 per cu. yd. The ash is very soft. Large lava boulders are embedded in it. Owing to the clay the material must be dried in the sun before washing in the usual way.

CALAVERAS COUNTY

A recent shipment from the Calaveras mine at Copperopolis averaged 10.02% copper, and netted $1090. The cross-cut on No. 4 level north shows improvement. On No. 6 level south the north face consists of 12 in. assaying 18.86%, and 60 in. averaging 3.37%. Experimental work continues at the mill.

ELDORADO COUNTY

A 10-stamp mill has been erected for J. Flynn at the Blue Rock mine near Georgetown.——The Georgia Slide mines have been surveyed by H. D. Jerrett of Placerville.

INYO COUNTY

On September 18 the lessee of the Cerro Gordo mine, Louis D. Gordon, will turn over the property to the company, his

lease having expired, but he will remain as manager. About 150 men are employed. The aerial tram to Keeler is carrying 100 tons of ore per day. The August output of zinc was 1620 tons. Up to September 18 the current month's yield is 1200 tons of zinc and 200 tons of lead.

Nevada County

(Special Correspondence.)—The full complement of 20 stamps is now dropping at the Union Hill mine. Production is $12,000 to $15,000 per month. The ore-shoot on the 770-ft., intermediary level has been opened for a distance of 170 ft., the east face is still in ore of mill grade. Two raises have been driven 200 ft. apart to a height of 135 ft., and a drift on the 700-ft. level has proved the ore for 200 ft. On this level the ore makes 50 ft. farther west than at 770 ft. and the east end still shows good ore. The company recently shipped 2.5 tons of tungsten ore to Denver, worth about $700. This ore occurs as scheelite in small bunches in the gold ore-shoots. This is the first shipment made.

Grass Valley, September 11.

The Union mine at Bear mountain, has been bonded to D. W. Shanks, J. Nelson Nevius, and other Los Angeles men, who have formed the Nevada County Gold Mining Co. The mine will be unwatered. It has been idle for several years.

The new 60-stamp mill at the Empire mine is crushing 8670 tons per month, almost double that of the old 40 stamp.

Plumas County

At the Walker copper mine, 22 miles from Portola, there are 150 men working underground and at mill construction. Machinery is arriving for the new plant.

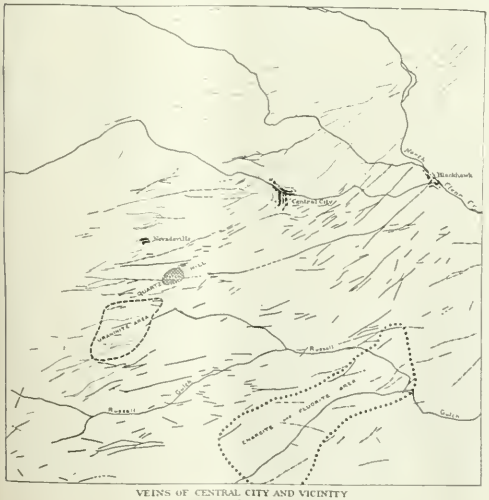
Shasta County

At the Noble electric smelter at Heroult one furnace is making ferro-manganese and another produces ferro-chrome. Ore for the latter comes from near Lowery in Tehama county.

COLORADO

Gilpin County

A detailed report on the economic geology of this county and adjacent portions of Clear Creek and Boulder counties, by



MINERAL DEPOSITS IN PART OF GILPIN COUNTY.

Edson S. Bastin and James M. Hill, is soon to be published by the U. S. Geological Survey. In *Economic Geology* for April-May, the former contributes an interesting paper on the ores of Gilpin county. It is presented with the idea of briefly giving the scientific results that are likely to be of most value to economic geologists. The region discussed is 30 to 35 miles west and northwest of Denver. It is the oldest lode-mining area in Colorado, being discovered in 1859. In Gilpin county the principal mining centres are Central City, Blackhawk, Nevadaville, Russell Gulch, Perigo, and Apex. The entire region lies within the area of pre-Cambrian rocks. Probably in early Tertiary times many igneous rocks intruded as dikes into the pre-Cambrian rocks, these intrusives being the 'porphyries' of the miners. Veins greatly exceed in number and importance all other structureal types of ore deposits of the region. Most of the orebodies occupy zones of minor faulting, and are true veins. These commonly strike between east-west and north 45° east, and dip at angles of 60° or steeper. Flat veins are rare. The width is often between 1 and 5 ft. The largest vein noted is the Mammoth near Central City, where it is traceable on the surface almost continuously for 6000 ft. The greatest depth to which a vein has been followed is 2250 ft. (on the dip), in the case of the California.

The ores of Gilpin county and adjacent areas described may be grouped according to the metals which give them their predominant value, into the following five classes: (1) Gold-silver ores, which constitute the main economic resource of the region; (2) uranium ores, highly localized but of much interest as a source of radium; (3) tungsten ores, which form the basis of the tungsten industry of Boulder county, the largest producing centre for this metal in the United States; (4) copper ores, poor in precious metals, represented solely by the Evergreen mine near Apex; and (5) titaniferous iron ores of Caribou, Boulder county, which are not commercially valuable.

The region forms part of a broad mineralized belt embracing most of the important centres of Colorado.

Lake County (Leadville)

The Yak Mining, Milling, & Tunnel Co. recently secured an extension of its lease on the Aladdin property, near the head of Big Evans gulch, for 10 years, also a bond for $600,000 to become due within that period. According to the manager, W. W. Davis, the tunnel will be extended into the area. The Diamond winze, 200 ft. below the face of the tunnel, has opened ore. The Vega winze is to be sunk 150 ft. deeper. From the portal in California gulch to the Diamond winze the tunnel has a length of about four miles. The face is 900 ft. below the surface. Its extension will bring it near the Mosquito range, in territory that has been little developed. The Yak company and lessees are regularly producing gold, silver, lead, and zinc-bearing ores.

A motor on one of the pumps at the Penrose shaft burned out last week, but it was quickly repaired.

About 500 tons of 15% carbonate of zinc is stored at the Western Zinc Oxide Co.'s plant. The daily capacity is 50 tons. The Company is paying off its debt to the original company.

San Juan County

Ore shipments from the Silverton district in August totaled 171 cars, equal to 3591 tons.——The Sunnyside mine continues to dispatch high-grade zinc ore.

IDAHO

Ada County

(Special Correspondence.)—The Ironsides mine, eight miles from Boise, is to be re-opened by the Black Hornet Mining Co., headed by Mrs. Hortense Adams. A wide lode has been worked out to 240 ft. depth. The ore averages $8 per ton. Deeper work is to be done. The property is well equipped with mine plant and a 20-stamp mill.

Boise, September 2.

Elmore County

(Special Correspondence.)—The Boise King Placers Co. has resumed work after a long dispute between shareholders. The

property is well equipped for hydraulicking. There are 1250 shareholders, more than any other company in Idaho. George J. Albert is superintendent.

Boise, September 2.

OWYHEE COUNTY

(Special Correspondence.)—The American Nitrate Co. of Chicago has erected a small testing-plant on Succor creek. The average content of the deposit is 4% potassium nitrate.

Boise, September 2.

SHOSHONE COUNTY (COEUR D'ALENE)

The Success company's earnings were $152,256 in August, of which $120,000 was profit. Six or eight cents per share will be distributed this month.——In a raise from the Keating adit the Caledonia vein was cut 40 ft. sooner than expected. It shows good ore.——The Hypothek is employing 26 men, and has commenced shipping ore from the 900-ft. level.——The Polaris claims near Osburn have been leased to W. E. Mann of Waverly, Washington. He will be in the market for machinery at an early date.

There is said to be a shortage of skilled machine-men in the Coeur d'Alene region. The wages are $3.50 per shift of eight hours.

MICHIGAN

THE COPPER COUNTRY

According to the *Boston Financial News*: August outputs are as follows,

Mine	Ore Tons	Mineral* Pounds
Tamarack	23,600	448,400
Osceola	136,815	1,915,000
Ahmeek	74,250	1,930,000
Wolverine	34,000	698,000
Mohawk	69,000	1,316,000
Franklin	13,000	261,000
Centennial	5,800	96,000
Allouez	48,825	862,000
Mass	30,000	540,000
Superior	19,400	388,800
Hancock	8,500	153,900
La Salle	13,300	240,500
South Lake	1,125	27,000
New Arcadian	.....	28,760
Isle Royale	63,000	853,500
Calumet & Hecla	290,000	7,940,000
Copper Range	104,000	5,004,000
Victoria	16,500	250,000
Quincy	.....	2,111,000
Winona	12,000	240,000
White Pine	20,800	686,400
Houghton	.....	40,000
Lake	5,400	93,500

*66⅔ metal.

Repairs to the turbo-generator at the Calumet & Hecla were completed on August 30, and all re-grinding plants of the company are working.

MISSOURI

JASPER COUNTY

Production of the Missouri-Kansas-Oklahoma region during the week ended September 5 was as follows: blende, 6048; calamine, 592; and lead, 835 tons, averaging $75.48, $58.04, and $49.81 per ton respectively. The total value was $531,517; and to date $15,780,527. The output is nearly 22,000 tons of concentrate per month, an increase of 4500 tons over this time last year. The Webb City-Carterville district contributes 8500 tons, and Joplin, 3000 tons. On September 1 wages of underground men were reduced 50c. per day, due to the reduced prices received for ore. Many operators made little profit in August.

Plants being erected or re-modeled in the region will increase the capacity by 3000 tons per shift. They include one 1000, one 500, one 400, two 300, two 250, two 200, and one 150-ton plant, and several sludge plants.

MONTANA

ELKHORN COUNTY

At the Boston and Montana company's property the main adit is in over 2000 ft. The west drift toward the Idanha vein is in 150 ft. in granite, and the east drift toward the Park vein is in 110 ft. in soft, highly mineralized ground. At 100 ft. east a 10-ft. vein was cut, containing considerable mineral and was broken up.

LEWIS AND CLARK COUNTY

(Special Correspondence.)—Mining development is on the increase in the Helena mining region, according to the Helena Mining Bureau. The King Solomon mine in the Clancy district, 15 miles south of Helena, has been taken over by the Monarch Mining & Milling Co. with ample capital. The mine is now being unwatered, and a large amount of ore is blocked out on the 400-ft. level for stoping. The ore at 600 ft. will be cut with 125 ft. of drift and cross-cut. The machinery has a capacity for 1200 ft. and is of the latest type. The King Solomon group is one of the oldest producers of the district that was tied up by financial difficulties and a bad accident in the workings a year or so ago. Ike Moreland, one of the principal stockholders, succeeded in making a re-organization, and the mine will be shipping regularly by the middle of September. About 40 men will be employed for a start.

Profit at the Franklin mine, owned by the Cruse estate, in the Scratch Gravel district, was $8000 in August. The Cullen Miller property adjoining the Franklin is blocking out ore. A discovery of 18 in. of high-grade gold ore was made on the 200-ft. level on August 30.

Helena, August 30.

If the city of Helena withdraws its suit over the water of Ten-mile creek against James Breen of the Porphyry Dyke mine in the Rimini district, he will erect a 500-stamp mill. A 20-stamp mill has been treating $2.25 to $3 ore, at a cost of 60c. per ton for mining and milling. The deposit is said to be of enormous dimensions.

SILVERBOW COUNTY

On Labor Day, September 6, Butte had a big day. It included first-aid contests, which were won by the Original team with 89.6%, followed by the Leonard with 89.2%. The work was well done.

The Butte & London shaft has been unwatered, a 1200-gal. per minute pump has been installed at 1100 ft., and sinking is under way from this point to 1600 feet.

NEVADA

According to F. M. Manson, general manager of the Utah Ore Sampling Co., who recently returned to Salt Lake City after an extensive tour of Nevada, there is more mining activity in Nevada at present than for years. Operators take a decidedly optimistic view of the metal market, and are expecting higher prices for silver. New districts are being opened, and new developments are reported in nearly all of the districts throughout the State. The recent discovery of gold in several new districts has given an impetus to the industry that heretofore was apparently in need of no stimulus. Mining men attribute the greater activity to the decided increase in prospecting that has been going on for some time past.

ESMERALDA COUNTY

A northeast drift recently started on the 800-ft. intermediate level of the Jumbo Extension has cut 5 ft. of $133 ore. The mine is shipping 80 tons of ore averaging $45 per ton.

At the Florence, the superintendent, Harry B. Clapp, is to commence exploring both walls of the Reily stope, which

produced about $2,000,000 in the early days of Goldfield. Developments at 250 ft. depth are very satisfactory.

HUMBOLDT COUNTY

Transport of ore in the Rochester district was greatly facilitated on September 8 when the Nevada Short Line carried its first trainload from the foot of Rochester hill to the mill, nearly three miles away. The extension of the line was recently completed up Rochester canyon to the foot of the tramway, which is also the portal of the Friedman adit; henceforth ores will go by rail instead of by teams. New rolling stock is being procured and the line will be able to handle all tonnage produced up to 500 tons per day, a quantity which cannot be mined until after the stopes are opened from the deep-level adit. This is in 775 ft., and should be complete to 1200 ft. in about 40 days. All of this work is being done by the Rochester Mines Co., which accounts for most of the operations in the district.

Owing to a breakdown, the Seven Troughs Coalition company's August gold output was only $48,000, against $70,000 expected for the full month. A new 100-hp. gas engine is working well. Just prior to the trouble the bullion yield per 16 hours was $2500. This was from a 20-in. vein at 1200 ft., south drift, assaying $2100 per ton. The average from all parts of the mine in August was $100 per ton.

MINERAL COUNTY

(Special Correspondence.)—The Golden Pen Mining Co. recently shipped 205 tons of ore that averaged $118 per ton; another lot of 19.5 tons assayed $1012 per ton. This shipment included 962 lb. worth $3.63 per pound; and 100 lb. valued at $18.84 per pound. Only two men have worked at this mine, but in less than a year they have shipped over $50,000 of high-grade ore. Only one carload shipment was made previous to that of last week, but it averaged $600 per ton. The owners report three stopes opened on the first level, showing the same class of ore as already extracted, from which regular shipments will be made.

From the Mims lease on the Queen Regent Merger mine a car of ore was dispatched last week having a gross value of $1150, this being the second car from this lease during the past 30 days. This ore occurs on the foot-wall; the mill ore being 5 to 7 ft. wide, and has increased from $12 per ton on the 80-ft. level, to $20 to $30 on the 100-ft. level. The main working shaft of the Queen Regent has reached a depth of 150 ft., and is being sunk at the rate of about 14 ft. per week.

The Last Hope mine, adjoining the Queen Regent on the west, is sending out another carload to the railroad for shipment to the Hazen sampler. The shipping ore of this mine is uniformly good, the last carload averaged above $90 per ton. Up to date the Last Hope mine has produced over $30,000 of ore developed to a depth of 250 feet.

From the C. M. Hempel mine a recent shipment was made that assayed $16 gold, $1.60 silver, and $20 lead per ton.

Rand, August 31.

NYE COUNTY

Owing to the holidays the Tonopah mines produced only 9037 tons of ore worth $188,626 during the week ended September 11. Lessees contributed 294 tons of this quantity.——The Extension mill is treating 260 tons daily, and a thickener is being installed.——A number of working faces in the Belmont mine are in better than average grade ore. Last week's silver shipments totaled 193,671 oz.——Developments in the Jim Butler continue to be good.

Some activity at Manhattan is as follows, according to the local Chamber of Mines on September 1: Preliminary negotiations are under way towards a combination of the three properties on Litigation hill, namely, the Manhattan Amalgamated, Earl, and Litigation Hill Merger companies, the new company to also include the Manhattan Milling & Ore Co.'s 10-stamp mill, sampler, and cyanide-plant. This arrangement appears to be attractive, as ore is developed in each of the three properties, especially between the lines of the Amalgamated and the Earl claims, where there is a fine body of developed ore from the 300-ft. level, the owner of the ore being undecided, but immediately available should a merger be consummated. Each company also owns an adequate mine plant, including pumps, hoist, cars, tools, track, buildings, etc., with a large ore-bin situated on the Earl property, and also as part of the Earl machinery, an air-compressor, with machine-drills, etc. With the company to control its own milling plant, it would mean that it could start mine and mill operations at a profit immediately, with practically no dead work necessary.

It is stated that the White Caps Mining Co. has made a good payment to creditors.——At the Big Pine mine some rich ore has been cut at 200 ft. The daily output is 150 tons. A new concentrator of Homer Snyder is being installed to save some gold that fails to be amalgamated.——Lessees are resuming at the Union Mine claim of the Dexter company.——The War Eagle mill has been treating material from the Big Pine waste dump of 75,000 tons, to see if it was profitable.——A new gravel deposit has been found in one of the gulches near Timber hill.

At the Train Chase lease on the Mustang a rich deposit was cut last week. It consists of a series of veins containing soft, decomposed quartz and talc, averaging $200 per ton. The material is in limestone, near the shale contact, 15 ft. below the surface.

NEW MEXICO

DONA ANA COUNTY

(Special Correspondence.)—It is reported that the Bennett-Stephenson, Torpedo, Memphis, and other properties in the Organ district are to be sold to W. Rowland Cox for $975,000. They were once profitably worked on a large scale. Some ore has been shipped from this district for some time.

Las Cruces, September 5.

OREGON

MALHEUR COUNTY

In Bulletin 620-B of the U. S. Geological Survey, the nitrate deposits in southern Idaho and eastern Oregon are described by G. R. Mansfield. The deposits, 26 miles by road southwest of Homedale, Owyhee county, were discovered in the spring of 1914 by D. J. Sullivan. The nitrate occurs in veinlets which have not been developed far into the rock mass. The richest part of the deposit is probably that already exposed, and as the rock is opened the veinlets may disappear.

TEXAS

EL PASO COUNTY

Exports of gold and silver bullion from Mexico through El Paso during the fiscal year ended June 30, 1915, were as follows:

Year.	Gold.	Silver.
1915	$ 1,372,750	$3,291,621
1914	245,244	1,270,786
1913	No report	No report
1912	625,725	2,334,607
1911	10,907,271	1,605,265

UTAH

JUAB COUNTY

The Tintic Smelting Co. is to be dissolved. It was incorporated in November 1906; the plant (cost $1,000,000) operated for about a year in 1908-1909. The property failed to pay because the Knight mines did not produce all the ores required to make a suitable flux, and other smelters in Utah contracted for all the available ores of the character needed, which made it impossible for the smelting company to operate. Part of the smelter will be used in constructing the new mill at Tintic.

SALT LAKE COUNTY

A 1000-ft. adit is being driven into the Steele claims in

American Fork canyon. Some ore is expected in a short distance. Three diorite dikes and a large porphyry dike will be cut farther in.

The Alta Tunnel & Transportation adit is in 1500 ft. The rock now consists of limestone stained with manganese. The flow of water is increasing all the time.——In the Cottonwood King company's adit at 975 ft. some rich copper ore has been cut. L. T. Wakeham is superintendent.——A carload of ore from the Emma mine to the Garfield smelter returned gold, $1.50 per ton; silver, 16.6 oz.; lead, 18.2%; and iron, 29%. The faulted area in the mine is being thoroughly prospected. The property is well equipped for expiditious work.——The Alta Consolidated is shipping two cars of ore to the smelter.

SUMMIT COUNTY

Ore shipments from Park City during August were as follows: Big Four, 216; E. J. Beggs, 110; Daly, 29; Daly-Judge, 2330; Daly West, 829; Silver King Coalition, 2941; Silver King Consolidated, 1491; and Utah Sampling Co., 26, a total of 8319 tons.

In October, the Silver King Coalition company will distribute 15c. per share, a total of $187,500. To date dividends amount to $13,584,885. Good progress is being made in installing the flotation apparatus in the mill.

WASHINGTON

STEVENS COUNTY

On Silver creek, 18 miles east of Northport, two prospectors named Johnson and Yoder are reported to have discovered a large outcrop of high-grade lead ore. The property is named the Electric Point. The nearest railroad is at Boundary, 12 miles away. According to Sidney Norman, a depth of 20 ft. has been reached, and 100 tons of clean galena and an equal quantity of carbonate ore has been extracted. There is little silver in the ores.

KOREA

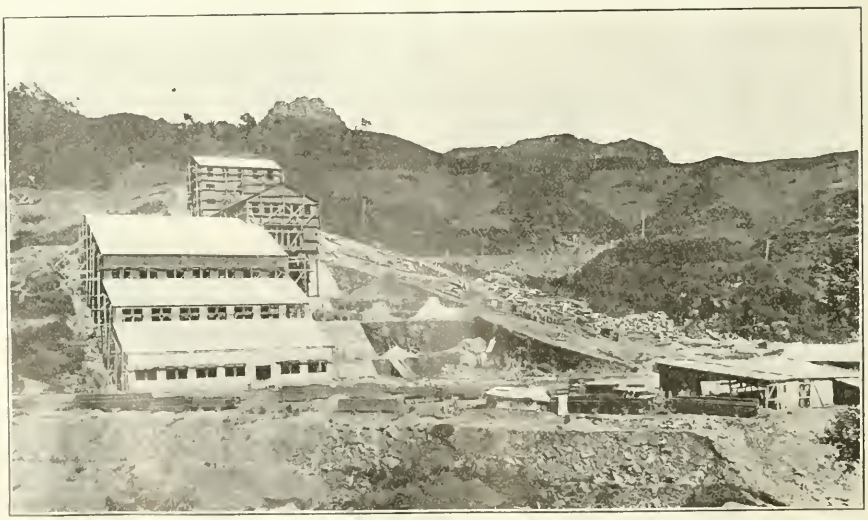
The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports the following results for August, at the Suan mill:

Ore treated, tons	6,368
Mill operated, days	25.5
Bullion	$42,500
Concentrate	24,800
Total value	$67,300
Operating expenses	$27,500
Net earnings	$39,800

The August output of the Oriental Consolidated mines totaled $127,800. In July the rainfall was 42 in., the subsequent floods reducing the output to $97,536 from 23,099 tons. The various plants yielded the following:

Tabowie	$24,584
Taracol	15,265
Maibong	16,398
Candlestick	2,101
Taracol cyanide-plant	34,941
Maibong tube-mill	3,696
Candlestick cyanide-plant	550
Total	$97,535

Between July 10 and July 30, inclusive, there was 41.75 in. of rain. This tremendous fall interfered with all operations, and caused much damage to the property. Many landslides and washouts took place in the Tabowie-Taracol valley. The acting-foreman at the Taracol mine, John Arthur, was killed by a landslide which destroyed his house at 0.30 A.M. on July 17, and 60 Koreans were killed by the flood the same night. All of the bridges were washed away, also a large part of the Taracol double track, between the mine and mill. The water pipe-lines to the Taracol mill were broken, and those to Tabowie mill were filled with sand. Both of the electric-power systems were stopped, as parts of the high-tension lines were washed away, and owing to the stoppage of power the mines began to fill with water. The company's hydro-electric plant was started after a shut-down of 26 hours, and Okura & Co.'s plant started after a stoppage of 38 hours. In



THE NEW TUL MI CHUNG MILL BEING ERECTED BY THE SEOUL MINING CO. ON THE SUAN CONCESSION. THE PLANT WILL TREAT 400 TONS OF ORE PER DAY. THIS PHOTOGRAPH SHOWS PROGRESS OF CONSTRUCTION ON AUGUST 1. OPERATION WILL COMMENCE ABOUT SEPTEMBER 20. WITH THE SUAN MILL THE TWO PLANTS WILL HAVE A CAPACITY OF 600 TONS PER DAY. FLOTATION IS TO BE USED AS A SUPPLEMENTARY PROCESS IN BOTH MILLS. ORES ON THE CONCESSION CONTAIN GOLD, COPPER, AND BISMUTH.

the meantime, pumping was done with steam, water from the mines was hoisted, and the water was kept from reaching No. 6 level of the Taracol mine, and No. 12 level at the Tabowie mine. At Maibong the rain was not quite so severe as in the northern part of the concession, and the Charabowie mine was not flooded on any level, as the water was allowed to accumulate behind the cement bulkhead on the south side of the shaft. There has been no rain since July 30. The damage is being gradually repaired. All of the mills are working at full capacity, but as the skips in shafts have to be used for bailing water a part of the time, ore sent to the mills comes from lower-grade stopes in the older upper parts of the mines, and from dumps on the surface. The Unsan and Chosan districts' cordwood railways suffered from the rains, which washed out fills and embankments and covered the tracks with large slides of debris. All of this has been cleared away, the lines have been repaired, and the trains are running. Some 7000 mining timbers were carried out of the Taracol yard by the flood; 4000 have been recovered. The extraction obtained in the Taracol cyanide plant during July was 76.2%. This is below the average, and the poor result is probably due to the irregular run, caused by the rains, which stopped the power supply and the delivery of concentrates. The extraction obtained in the Maibong tube-mill in July was 108.6%. This abnormally high recovery is due to having changed over from grinding in water to grinding in cyanide solution, and the results obtained during July make up for the June deficit. The Chorrie reservoir is full.

CANADA

British Columbia

The Hudson Bay zinc mine on Deer creek, in the Sheep Creek district, is being bonded by R. K. Neill of Spokane. From 30 to 40 men will be employed, and large shipments made.

On September 30 the Hedley Gold Mining Co. will pay a quarterly dividend of 3%, and an extra of 2%.

The Standard Silver-Lead company at Silverton has made arrangements, to sell its zinc concentrate, with a United States company. At present there is on hand 2500 tons assaying 43% zinc and 30 oz. silver per ton. The daily output is 20 tons of this product. Only lead concentrate has been sold lately, at the rate of 1300 tons per month to the Trail smelter. September earnings are expected to be abnormally high on account of the zinc.

Last week the Trail smelter received a total of over 10,000 tons of ores and concentrates, the first time this year to exceed that quantity.

The Slocan district is in a thriving condition.

Ontario

The McKinley-Darragh Savage company will pay a dividend of 3% on October 1, equal to $67,431. The total to date is $4,607,000, or 205%.——A 100-ton mill is to be erected at the Teck-Hughes, also a power-plant. Buffalo people are interested.—— The Porcupine Crown mill is treating 50 tons of tailing daily, in addition to 100 tons of ore from the mine. Development at 600 ft. is encouraging.——The new vein has been cut at 100 ft. in the Keeley at South Lorrain. It is of good width and grade.——A high-grade narrow vein has been cut at 200 ft. in the Currie mine.

MEXICO

Hidalgo

The Santa Gertrudis company reports as follows for the second quarter of 1915: ore treated, 41,557 tons; bullion extracted, $249,000; net profit after paying working expenses and London office, $76,000. Development amounted to 4782 ft. in the upper parts of the mine. Of this, only 835 ft. was in average low-grade, though profitable, ore. The mill worked at 40% capacity until late in June, when it was increased to 60%. On July 13 it was closed on account of shortage of lime. A period of very irregular operation appears probable.

PERSONAL

Robert E. Kinzie is at Salt Lake City.

Jay A. Carpenter is here from Tonopah.

J. A. Daniel has gone from London to Bolivia.

E. K. Craig is returning to Skidoo, California.

Richard Baird is here from Greenhorn, Oregon.

John W. Finch was at Salt Lake City this week.

H. W. Hardinge has been at Cobalt and Porcupine.

Fred. B. Ely of Salt Lake City, is in this city, on his return from Alaska.

Wallace E. Pratt, Chief of Division of Mines, Philippine Islands, is at Berkeley.

Donald F. Irvin has returned to Pasadena from Central America and the Canal Zone.

Frank H. Sistermans and D. M. Munro, recently in Mexico, are attending the Engineering Congress.

John S. Colleran, auditor of the Seoul Mining Co., will return to Korea by the *Chiyo Maru* on October 2.

D. C. Jackling passed through Phoenix, Arizona, on September 7, on the way to the Ray mine and Hayden smelter.

George T. Holloway has left London for Ontario to work with the Nickel Commission, of which he has been appointed chairman.

R. A. F. Penrose was here with the intention of attending the Engineering Congress, but had to return to Denver last Wednesday.

H. H. Webb was seriously injured in a motor-car accident last Sunday in San Francisco, but he is doing well, we are glad to add.

J. B. Tyrrell was prevented, at the last moment, from coming to San Francisco, being called to inspect the new discoveries at Kowkash, Ontario.

B. F. Wade, hydraulic engineer, has joined the staff of the Redwood Manufacturers Company with headquarters in the Hobart Building, San Francisco. Mr. Wade will confine his attention to the design and construction of wood-stave pipelines for power, irrigation, and water-supply purposes.

Schools and Societies

The Montana State School of Mines re-opened on August 31 with 20 new students. Others are expected. The junior class is surveying the Moonlight mine at Butte. The senior class is soon to visit the East Helena smelter. The faculty at the School which is a branch of the State university, consists of C. H. Bowman, president, and G. W. Craven, Theodore Simons, Bancroft Gore, D. C. Bard, A. E. Adami, and L. J. Hartzell, professors.

The Southern California section of the A. I. M. E. states that in order to make its meetings more interesting and fruitful, the executive committee has formed a sub-committee on programs for section meetings. It announces for the coming autumn and winter season, four dinner meetings, at intervals of two months, in which the co-operation of all section members is urgently requested. The subjects chosen for discussion at these meetings, with the proposed dates, are as follows: September 28 'Mining Geology of Mojave County, Arizona;' December 14, 'General Geology and Mining Conditions in Southern California;' February 1, 1916, 'Petroleum, Its Geology and Technology;' and April 4, 'General Mining Conditions in South America.' Notice of the hour and place of each meeting will be issued later.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, September 16.

Antimony	35 —35¾
Electrolytic copper	18½—18¾
Pig lead	4.75—5.70
Quicksilver (per flask)	$90
Spelter	17 —17¼
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	28

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, September 16.—Copper is firm owing to advances in London; on account of overstock, lead is dull; spelter is weak and dull.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	13.60	19.75	Dec.	12.75	....

Exports of copper during the week ended September 8 totaled 8,123,441 lb., worth $1,542,133. France secured 3,799,811; England, 2,903,349; and Sweden, 1,120,350 lb. Imports amounted to 4,184,091 lb., valued at $592,739. Of this, 2,932,602 lb. came from Peru, and 832,580 lb. from Japan.

Dividends declared are as follows: Chino, 75c.; Magma, 50c.; Nevada, 37.5c.; Phelps-Dodge, $2.50 and $3; Ray, 37.5c.; and Utah, $1 per share.

In August the East Butte produced 1,785,000 lb., and Greene Cananea, 2,902,000 pounds.

On account of a dispute over wages several thousand men at the Clifton, Morenci, and Metcalf districts of Arizona went out on strike early this week.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Sept.	9	Aug. 4	47.08
"	10	" 11	47.27
"	11	" 18	47.33
"	12 Sunday	" 25	47.08
"	13	Sept. 1	46.77
"	14	" 8	48.20
"	15	" 15	48.56

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	57.58	48.85	July	54.90	47 52

May	58.21	49.87	Nov.	49.12	....
June	56.43	49 03	Dec.	49.27	....

The above quotations indicate an uncertain market, and it is difficult to state what is the disturbing factor. On September 14 the Director of the Mint purchased 250,000 oz. at 48.75c., and 250,000 oz. at 49c., for the Philadelphia Mint.

Exports from London to India and China to August 25 total £4,506,500, against £3,201,250 in that period of 1914, a decrease of, say, 13,500,000 oz. Imports of merchandise by England from China in the first half of 1915 show an increase of 63%, while exports to China fell off 52%. This remarkable falling off necessitates a substitution of so much silver, or credit in some form based on silver, in order to balance the altered conditions of trade, according to Samuel Montagu & Co. It is possible that the balance of trade between China and other countries, especially the United States, may not have altered in the same proportions, but it is reasonable to assume that the movement of trade was somewhat similar. If this assumption be correct, it is hardly probable that China is in a position to re-sell permanently any portion of the large stock held in London on account of that country, though, possibly, there may be occasional attempts to make a favorable sale with a view to replacement at a profit.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest produeer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

The U. S. Geological Survey has issued Press Bulletin 234, covering the spelter situation during the first half of 1915.

The Missouri-Kansas-Oklahoma output in the week ended September 11 was as follows: blende, 5655; calamine, 502; and lead, 803 tons, averaging $72.10, $65.78, and $48.05 per ton respectively. The total value was $479,289.

On September 30 the Butte & Superior will distribute 75c. and $5 per share, making $9.75 for the current year. The August output was 13,878,981 lb. zinc from 45,140 tons of ore. The main shaft at 1750 ft. is in 27.6% ore.

The Canadian government is to buy all of the zinc produced by the new plant at Trail, British Columbia.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	37.85	34.40	July	31.60	37.38
Feb.	39.76	37.23	Aug.	50.20	34.37
Mch.	38.10	48.76	Sept.	33.10	....

May	33.29	39.28	Nov.	33.51	....
June	30.72	40.26	Dec.	33.60	....

On September 16 tin was quiet at 33 to 33.50 cents.

Eastern Metal Market

New York, September 10.

The entire market is generally dull and weak, aluminum being the only exception. The recent advance of electrolytic copper to 18c. did not carry with it the confidence of consumers, and substantial concessions since then have failed to rouse them to activity. It is notable that sellers of small lots are doing as little as the larger sellers, and the entire trade is puzzled. Zinc has continued to decline in a dull market. Fear of labor trouble in the ore district is causing uneasiness. Contrary to all expectations lead has been reduced $4 per ton by the A. S. & R. Co. Large consumers of tin for export, in the form of finished products, are disturbed by more stringent regulations which Great Britain has ordered. The new restrictions will add to the difficulties which the tin-plate mills experience in their export business. Food containers are specially mentioned. The antimony market is a waiting one. Aluminum is now nominally quoted at 40 to 45 cents.

Semi-finished steel and pig-iron continue to advance. The steel industry is making new records. The Steel Corporation in August produced more ingots than in any other month, as did the independent companies as a whole. The pig-iron output in August was 2,779,647 tons, or 89,666 tons per day, against 82,691 tons in July. The capacity of the 249 furnaces in blast on September 1 was 91,075 tons per day, which was only exceeded in February and April 1913. Steel billets have sold at $26 and $27, Pittsburg. The demand for steel to be manufactured into shells continues enormous, and over 3c. per lb. has been paid for rounds. Thousands of tons are seeking placement. In the machinery end, a feature is the large number of manufacturers who have engaged in the building of machine-tools, especially lathes. So far, there has been a ready sale for them.

COPPER

The market has been dull to the point of stagnancy, and jobbers as well as the producers and dealers in wholesale quantities of copper are complaining of the lack of business. All are asking themselves, and others, what the trouble is. The retailers say they never saw anything like the present lack of demand, while the large dealers are wondering what has become of the War consumption. The best explanation is that these are strange times. Unusual symptoms are encountered by those who try to diagnose business conditions, and the prophets are all awry. No one can read even a few days ahead, to say nothing of trying to forecast what a few weeks or months will bring. The exports of unmanufactured copper are exceedingly small, totaling but 3442 tons in the first 10 days of September. Of course, a great deal of metal is going abroad in the form of munitions, but the exports, coupled with purely domestic consumption, do not seem sufficient to offset the large production which, admittedly, is running ahead of deliveries. It is to be regretted that authentic figures such as were formerly issued monthly by the Copper Producers' Association are not available. For a time, after the price of electrolytic advanced to 18c., New York, about August 26, the producers endeavored to maintain that figure, but repeated efforts to stimulate consumers by lower offerings have been made. As usual, second-hands led in offering concessions, but these were of little avail. The fact is that the rise was too rapid and simply augmented the conservatism of buyers. It is reported that producers have invited bids at 17.25c., while second-hands are ready sellers at that figure. In the absence of buying, prices are entirely nominal. Lake has been dormant since sales were made at 18c. Foreign exchange per pound sterling was quoted on September 10 at $4.69¼. Its advance from the low point of $4.50 had a salutary effect on the market, but was not sufficient to start buying.

ZINC

Quotations continued to decline until yesterday, 14c., New York, and 13.75c., St. Louis, was asked for prompt delivery. The market, except for flurries of inquiry, has been dull. On September 7 the inquiry was sufficiently definite to establish prompt at 14.50c., New York, September at 14c., and last quarter at 13.50c. Brass-mill special could have been bought at a premium of about 2c. over these prices. 'Bertha' is no longer quoted, but 'Horsehead' is still around 40c. As with copper, the general idea that production far exceeds consumption is a depressing influence. Something of which little is being said, but which, nevertheless, is causing worry, is a growing unrest on the part of labor in the Western mining regions. Should trouble come in this direction prices will surely advance. Manufacturers of brass and copper products have not yet resumed the quoting of base prices, more because of the unsettled condition of the spelter market, than because of the price of copper. Painted barb wire is being exported in large quantity in place of the galvanized product. It is quite as satisfactory for use in the construction of the entanglements used in military operations. Exports of spelter since the beginning of the War, according to C. Mayer, secretary of the New York Metal Exchange, total 9946 tons from foreign, and 114,405 tons from domestic ores. Exports from September 1 to 10 amounted to 653 tons.

LEAD

In the face of predictions that the quotation for lead was likely to remain at 4.90c., New York, for at least a few weeks, the A. S. & R. Co., on August 9, reduced its price 20 points—$4 per ton—to 4.70c., New York. It is true that independents had been selling at 4.82½c., New York, but the quantity dealt in was not thought to be large enough to have any great effect. After the announcement, the outside sellers reduced their quotation to 4.65c., New York. Previous to the decline, the St. Louis quotation was 4.75c., although it was intimated that 4.72c. would be accepted. Exports of lead since the beginning of the War total 32,442 tons in bond, and 76,346 tons domestic. Since September 1 exports amount to 848 tons.

TIN

The trade is seriously disturbed by amendments to the guarantees which England exacts from the importers and purchasers of tin. In a special notice, under date of September 9, the Tin Committee of the New York Metal Exchange set forth the changes.

As for the market, it has been extremely dull. Prices stiffened a little with the betterment in foreign exchange, but buyers have not taken hold. The quotation for spot, New York, was 33.25c., September 7, and 33.12½c. on the 9th and 10th. Arrivals up to September 10 totaled 1495 tons, and there was afloat on that day 5163 tons.

ANTIMONY

Waiting for buyers has been about all sellers have had to do in the past few weeks. There is plenty of Chinese antimony which can be had at 28 to 29c., duty paid.

ALUMINUM

Many complaints are heard of the inability to secure spot aluminum in the form of sheets and rods, and manufacturers are looking about for substitutes, where the lightness of aluminum is not absolutely essential. In pressed form it is being used in the manufacture of shrapnel fuse-timers, and this with the continued heavy demand from automobile makers has made spot and nearby metal scarce. Meanwhile the nominal prices have mounted to 40 to 45 cents.

BOOK REVIEWS

The Sampling and Chemical Analysis of Iron and Steel. By O. Bauer and E. Deiss, translated from the German by William T. Hall and Robert S. Williams. P. XIV, 373. Ill., index. McGraw-Hill Book Company, Inc., New York, 1915. For sale by the Mining and Scientific Press. Price, $3.

A third of this book shows by numerous examples, illustrations, and diagrams, how difficult it is to obtain a correct sample of iron and steel and also discusses the erroneous results obtained when the influence of segregation is neglected. It was the thorough treatment of segregation in the German edition that led two members of the chemical staff of the Massachusetts Institute of Technology to translate the book. To the accurate German methods of analysis the translators have added 25 less laborious procedures fitter for American laboratories and an accurate method for the determination of combined oxygen.

Standard Handbook for Electrical Engineers. Prepared by a staff specialist, Frank F. Fowle, editor-in-chief. Fourth edition. P. xvi, 1984. Ill., index. McGraw-Hill Book Co., Inc., New York, 1915. For sale by Mining and Scientific Press. Price, $5.

This is a handbook for specialists. In its preparation the publishers have divided the entire field of electrical engineering into 25 sections, each complete in itself; the index references are to section and paragraphs; a thumb-index facilitates reference. In this edition (about 400 pages longer than the previous one) a new section, No. 25, has been added on General Engineering and Central Station Economics. The bibliography annexed to each section is most valuable. Section No. 19 on electro-chemistry is full of valuable information for the metallurgist. Unusual uses of the electric-furnace are the production of the volatile substances bisulphide of carbon, zinc, and phosphorus. The statement is made that when coke costs $7 per ton, and electric energy $10 per annum, the cost of production of iron in an electric-furnace is approximately the same as in a blast-furnace.

Annual Report of the Smithsonian Institution for 1914. P. 729. Ill., index. Washington, D. C. Government Printing Office, 1915. Can be procured through the Mining and Scientific Press.

An extraordinary collection of information, ranging from articles on the constitution of the atom to modern theories regarding the sun. There is something to suit the most bizarre taste. Sad reflections arise on reading the account of a successful flight of Langley's aeroplane. By an unfortunate accident to the launching gear in December 1903 Langley missed the honor rightly due to him as the first successful aviator. Still more depressing thoughts come on seeing the perverse ingenuity applied to the manufacture of explosives. The picture of the 16-in. shell, weighing 2400 lb., with its powder charge of 666½ lb., is terrifying, but the plate showing the 3-in. high explosive shell with the thousands of payments resulting from its explosion shows more clearly diabolical nature of war. Of special mining interest is an article on the Klondike and Yukon goldfields wherein is shown the geological changes made by dredging and hydraulicking. The geology of the bottom of the sea and climates of geological time, together with the form and constitution of the earth, gives new ideas concerning our planet. Future generations are thought of in the article on play school for children carried on in connection with the summer school of the University of California; this is perhaps the most useful article in the book. The anthropologist will find astonishing types of humanity in an article on early inhabitants of western Asia.

Commercial Paragraphs

An electric-furnace for melting 24 tons of steel per 24 hours has been ordered by the Canadian Brakeshoe Co., Quebec, from the Snyder Electric Furnace Co. of Chicago.

Norman B. Livermore & Co., of Los Angeles, announces that C. A. Baechtold, of the Lidgerwood Manufacturing Co., has joined the firm. His headquarters will be mainly at 1106 Hibernian building, Los Angeles, but he will also cover San Francisco territory at intervals.

The International High Speed Steel Co., with works at Rockaway, New Jersey, has published a neat little pocket-volume of 56 pages. Full details are given about the company's types of steel produced, and its treatment, including mining and solid and hollow rock-drill steel. A lot of useful data is spread throughout the book.

The Hardinge Conical Mill Co., New York, has received an order from the Nevada Consolidated Copper Co. for two 8-ft. diameter Hardinge mills to be used with iron balls: also an order from the Dome Mines Co., Ltd., of South Porcupine, Ontario, for two 8-ft. diameter ball-mills. These ball-mills are to take the place of stamps now in use at the Dome mill.

The following awards have been given the United States Steel Corporation and subsidiary companies by the Panama-Pacific Exposition: The Corporation, two grand prizes, special gold medal, and three medals of honor; National Tube Co., grand prize for the general excellence of its tubular products and fittings, greatest merit being recognized in the well known specialties; medal of honor for each of the following: Oliver Iron Mining Co., Pittsburgh Steamship Co., Pittsburgh and Conneaut Dock Co., H. C. Frick Coke Co., Duluth, Missabe and Northern Railway Co., Carnegie Steel Co., and Illinois Steel Co.; gold medals for each of the following: Bessemer and Lake Erie Railroad Co., Birmingham Southern Railroad Co., Duluth & Iron Range Railroad Co., Elgin, Joliet and Eastern Railway Co., Newburgh and South Shore Railway Co., Union Railroad Co.; and grand prizes each for the Carnegie Steel Co., Illinois Steel Co., Tennessee Coal, Iron and Railroad Co., Lorain Steel Co., American Bridge Co., American Sheet and Tin Plate Co., American Steel and Wire Co., and the Universal Portland Cement Co. Gold and silver medals were awarded the various collaborators of the entire exhibit which covers one-fifth of the area of the Palace of Mines and Metallurgy.

The Western Electric Co., New York, sends us the following: The pneumatic hammer, which has held first place in coal mining, will meet keen competition from a new electric hammer that has just appeared on the market. The hammer, known as the 'Number 8,' has been brought out by the company, and is similar in appearance aud construction to the 'Number 7' recently put on the market by the company. The new hammer is heavier and more powerful than any of its predecessors, which will make it available for heavy duty mining work. It is recommended for taking up bottom, sweeping the roof in gangways and headings, and doing other rock excavation incident to coal mining. The greatest recommendation that this electric hammer has is its economy, and it is claimed that it will run at a power saving of 85% over air. It is more flexible; needing only a pair of wires, while the air-hammer needs a compressor with its attendant piping and incidentals. Flexibility, simplicity, and economy should make the electric hammer popular in the mine.——The Portland, Oregon, branch of this company has moved to a well equipped new brick and concrete building at East Ash and Union streets.

Additional train-despatching facilities are to be installed by the Illinois Central and Atlanta & West Point railroads. The former's plans call for 10 complete stations, making 60 in all, and the latter's plans require 13, making a total of 43. The Western Electric Co. will supply the apparatus.

EDITORIAL

T. A. RICKARD - Editor

UNDER Mining News we give a telegram received, when we were going to press, from a trusted correspondent at El Paso, summarizing the position in Mexico as it affects the mining industry.

IN the first year of the War the total gross tonnage of shipping captured, detained, sunk, or damaged amounted to nearly 4,000,000 tons, distributed among 3000 vessels. Of these, 418 vessels were neutral, 521 German, 476 British, and 75 Austrian.

AMONG the ceremonies incidental to the International Engineering Congress was to have been the presentation of the John Fritz medal, awarded this year to Mr. James Douglas. The ceremony was postponed on account of the absence, through illness, of the recipient. The Fritz memorial medal will gain in lustre by association with the name of James Douglas.

CYANIDATION of sand and slime from the mills along the Mother Lode in Amador county is not a success, save in one or two instances. Graphitic slate or schist is the trouble. Amalgamation and concentration yielded an average of 85%, from 629,000 tons of $4.89 ore, in 1914. The slime assays over $1 per ton, and is worth treating. Recent experiments seem to suggest a way out of the difficulty: amalgamation followed by flotation will recover the concentrate and remove the graphite, while permitting cyanidation of sand and slime, thus adding considerably to the gold output of the region.

PERSONS are said sometimes to be conspicuous by their absence; a process may be said to be renowned by the omission to mention it at a meeting of the American Institute of Mining Engineers and likewise at an Engineering Congress. "The bubble reputation" of flotation will not lose thereby, even if the technology suffers. It is curious that silence on the subject was so completely preserved during the proceedings of the last two weeks in San Francisco. However, this paper has endeavored to restore, and will continue its efforts to restore, the balance between silence and publicity on a metallurgical process of such insistent importance.

AFTER a period of apparent inactivity the Western Federation of Miners has started a strike at the copper mining and smelting centres of Clifton, Morenci, and Metcalf, all in Arizona. Several thousand men, including a large number of Mexicans, are employed there. Wages are paid on a sliding-scale based on the price of copper, and the pay is good; but evidently the men, led by labor agitators, are not satisfied with their lot, and so have 'downed tools,' compelling a shut-down of the mines and reduction works. This district produces about 6,000,000 pounds of copper per month, the properties being operated by the Arizona Copper, Detroit, and Shannon mining companies. The effort of the Western Federation to dominate the labor-unions in Arizona will, we hope, meet with a failure similar to that which befell the Moyerites in Michigan and Montana. For the solidarity of labor we have respect and sympathy; for the propaganda of an anarchistic coterie only anathema.

FOR countless generations nations have striven to accumulate gold; the nation with the most gold per capita was considered the financial leader. Now a novel situation has arisen and with it a new doctrine. The United States is accumulating gold too fast, but instead of rejoicing, our leading bankers are preaching that unless great wisdom is displayed, this influx of gold may lead to financial demoralization. The bankers argue that there is a normal status of equilibrium between the various countries of the world as regards gold holdings. This normal status is now upset by the influx of gold from Europe. This excess of gold is likely to lead to unwise extension of credit, unwarranted starting of new enterprises, and over-speculation. With the cessation of the War the gold will be withdrawn, with the possible result of a disastrous financial disturbance. All this is what might happen, but forewarned is forearmed. The leading bankers of the country are trying to arrange for the payment of the debt due from Europe in interest-bearing securities or dividend-paying shares in profitable properties either in the United States or abroad.

DURING this week of conventions, speeches, and papers, one feature emerges clearly, namely, the recognition of public service. Amid all the distractions of the moment the most memorable episodes have been the tributes to General G. W. Goethals and to the late Joseph A. Holmes, to the quick and the dead. The engineer of the Panama Canal was the first speaker at the International Engineering Congress. He spoke modestly of his own achievement and did not fail to acknowledge the usefulness of the work done by his two predecessors. Those who heard him were impressed with his sense of public duty and the force of character that enabled him to stay with his task until it was finished. At the special meeting of the Mining Congress that was set aside as a memorial to Holmes, the brief tributes of respect offered by a number of representative men all dwelt upon his devotion to duty, his sincerity of purpose, and the con-

sistency of character that enabled him to make an enduring contribution to human welfare. In both cases the word 'loyalty' was in frequent use, the loyalty to public service that elicits the devotion of associates and assistants in any great enterprise. It is no less remarkable that the appointment of Mr. Van. H. Manning as the second Director of the Bureau of Mines has evoked general approval primarily because it is known that he showed unswerving loyalty to his chief. The public shows a right instinct in assuming that such loyalty to such a chief is a guarantee of faithful service for the Nation.

The Institute Meeting

The San Francisco meeting of 1915 will, we believe, go down in the chronicles of the American Institute of Mining Engineers as one of the most successful. The two days of business and the additional two or three days of pleasure were full of incident, from the informal reception at the Bellevue hotel on the Wednesday evening to the garden-party in Berkeley on the Sunday afternoon. While the opening ceremony was not graced by any State or City official, the speech of welcome consisting of sundry well-worn fragments of oratorical confectionery delivered by a henchman of Governor Johnson, yet the occasion was redeemed by a vigorous speech from the President of the Institute, Mr. W. L. Saunders, who was able to give the Governor's delegate a not inconsiderable amount of valuable information on the part played by mining in the industrial community, more particularly of California. Mr. Saunders dealt with the same theme on the following day, when he received one of the medals presented by the Exposition authorities to the engineering societies. We take pleasure in giving the full text of his eloquent address on another page. The reading and discussion of papers may be said to have constituted a minor feature of the meeting, not many of the authors being present. On such occasions most of us prefer to chat with old friends in the lobby instead of listening to the labored summaries of papers that we can read at our leisure. The best discussions, we are told, were those on covellite at Butte and on copper leaching, provoked by the papers respectively of Mr. A. Perry Thompson and Dr. L. D. Ricketts. A delightful rumor points to the latter as the next President. The banquet at the Palace hotel was graced by the ladies and proved a most agreeable function. Mr. Van. H. Manning received a warm welcome on his first appearance since his promotion to the directorship of the Bureau of Mines. The speeches were not remarkable, but Mr. Edward Benjamin proved a most acceptable toastmaster. On Saturday 200 members and their womenfolk enjoyed an excursion on Mr. D. C. Jackling's yacht, viewing the Exposition from the water and visiting the Selby smelter. On Sunday a large number accepted the invitation of Mr. and Mrs. Charles Butters to a garden-party, which, thanks to a perfect hospitality and a lovely afternoon, proved most delightful. Fortunately every day of the meeting was fair, California proving true to tradition. This enhanced the architectural beauties of the Exposition, which, of course, absorbed all the spare time of our visitors. Most of us will have been stimulated by the renewal of old acquaintances and the warming of ancient friendships. That, after all, is the best feature of such conventions. Indeed, the gathering was notable for the large number of distinguished veterans that were present. This speaks well for the renewed interest taken in the activities of the Institute by the most influential portion of the membership. However, several notable members were conspicuously absent: Mr. W. R. Ingalls, the editor of the *Engineering and Mining Journal,* had been expected; so had Mr. J. Parke Channing and Mr. Philip N. Moore. We are sorry that Professor Kemp was unable to preside at the geological session, his absence being doubly regrettable because due to illness. We speak for many in wishing him a speedy recovery from the effects of over-work. In concluding this brief account we deem it only proper to associate the success of the arrangements with the name of the chairman of the executive committee, Mr. Charles W. Merrill. To him and to his wife, as chairman of the Ladies Reception Committee, is due a grateful acknowledgment, which we venture to make, not officially, but out of knowledge of the facts.

Fool Luck

The Greenhorn mine, the Green Emigrant, and the Lucky Boy are actual names of Californian mines. These, and many similar names, record the good fortune that often comes to the unskilled. The Green Emigrant recalls a hot day in the 'fifties when a tired miner, who was ground-sluicing in the bottom of a gulch, was accosted by a pair of lately-arrived Germans, who could hardly talk English. "Vere shal ve vork?" they asked. The miner was weary. Scanty returns had embittered him; the shade of a tree, far up the hillside appealed to him: "Up there, under that tree," he said. After supper he laughed with his chums at the stupidity of the greenhorns hard at work on a side-hill, far above any possible chance of finding gold, which, as all the experienced diggers knew, was found only in the streambeds. The Germans worked stolidly, uncomplainingly, egged on by the miners, who thought that a few days hard work would teach the newcomers a useful lesson and, in the meantime, keep them out of the crowded ravine. The emigrants, instead of becoming disgusted, seemed quite happy in their work, much to the surprise of the miners below, who were astonished to learn that rich gravel had been struck in the shaft sunk on the barren hillside. The green emigrants had found one of the fossil rivers, or deep leads, that have since yielded their golden sand so bountifully.

A similar story is that of the Swede, Charles Anderson, who struck it rich in the Klondike. He was a pick-and-shovel miner at Forty Mile. One day in 1897 he invested some of his earnings in a series of drinks that

left him at the mercy of two marauding prospectors, who sold him No. 29 Eldorado, which they thought worthless, for $600, his total savings. Next day the Swede found himself with a headache, less $600, plus a claim somewhere up the river. He was frantic. But to no avail. The two perpetrators winked the other eye and left camp for Quartz creek while Anderson decided that he must go and test his claim. He did; he went 80 miles to Eldorado creek and sunk 18 feet on No. 29 where on bedrock he found a fortune. A few days later the two wise men from Quartz creek, on their way to Dawson, passed the Swede at work and asked him, in jest, how he was faring. He answered: "Ay tank Ay got some gold here" and showed them a pan with $1400 in it. The claim yielded $1,250,000.

History repeats itself. This time in Alsace, ignorance has proved profitable. An ancient spinster was persuaded by a geologist to bore for coal in her small forest-estate. The geologist was at fault; no coal was found. When a depth of 1000 feet was reached the lady's funds gave out; relatives and friends of the obstinate old lady came to her relief; they formed a new company, called the Bonne Esperance. With the new capital, the boring was continued, yet no coal was found. But at a depth of 1900 ft. a strange deposit was cut, a mineral by turns white, gray, or a fine brick-red, in shining crystals; it was a salt of potassium in large amount: a fabulous fortune. In all 300,000,000 tons—so it is said— of potash salts has been developed, the estimated worth being $13,000,000,000. The district containing the deposits is being attacked by the French; if they succeed in holding these mines their yield will aid greatly in repaying the losses of the War. So it is said.

The Mexican Fiasco

The A. B. C. and the B. U. G. conference of August 11 was followed by an ultimatum to the factions in Mexico. That ran its course until September 13, when the same mediators, with Secretary Lansing, re-assembled in order, apparently, to inform one another of the absolute failure of their pronunciamento. On October 9 they are to meet again, presumably to make another declaration of policy that will prove just as futile. In August the Mexican leaders were given reasonable time to get together and establish a stable government. They were invited to send delegates to a conference. Villa, Zapata, and others who were getting the worst of the desultory civil warfare agreed to do so; Carranza refused, claiming that he and his supporters constituted a *de facto* government. Last week the mediators decided to recognize the Mexican faction best fitted, "materially and morally, to protect the lives of foreigners and nationals." Nobody is mentioned as coming within this description, but General Carranza undoubtedly will jump to the conclusion that the description is a veritable portrait of him and of nobody else. Meanwhile we are assured that "there is no disposition on the part of the Administration to interfere actively in the affairs of Mexico." That seems fairly evident. Moreover, we are informed that "the manner of arriving at the Mexican party which shall finally receive the endorsement of the United States and Pan-American governments was left to individual representatives." So that no unity of action is presumed. As the government to be recognized "must possess the material and moral capacity necessary to protect the lives and property of nationals and foreigners," it is clear that the aforesaid recognition is postponed to the Greek calends. Mr. Carranza may have some "material" advantage over Messrs. Villa and Zapata, but any editor is bound to delete the word "moral" out of the text. Truly it is a sad mess. The immediate effect of the New York conference has been to compel a recall of the consuls—both American and European—and their nationals out of northern Mexico, because the apparent intention to recognize Carranza constitutes a declaration against Villa and his rule in the states of Chihuahua and Sonora. It will also antagonize the Zapatistas in Morelos, Guerrero, and Michoacan. Those who are familiar with the real state of affairs in Mexico are of the opinion that Carranza is utterly incapable of forming a stable government. If he is recognized and supported, we may expect one of his generals, say, Obregon, to start a revolt at an early date, breaking away as Villa did. A rumor that the Pan-American conferees may choose Alvaro Obregon as a provisional president is more hopeful. That would mean the recognition of the Constitutionalist party, but not of their First Chief, as he calls himself, Venustiano Carranza, who is an obstinate and pompous person without the faculty of inspiring loyalty in his associates. The choice of Obregon would placate Villa and Zapata and minimize the chances of a new revolution. If Obregon is chosen and strongly supported, order may be restored. We cannot see how any conference of diplomats is to bring order out of chaos. Force can be countered by force alone. To talk morality to the factions in Mexico is likely to be as effective as the singing of a hymn to a burglar. Famine may be the force that will presage peace. These 'generals' fighting for the sacred cause of Liberty have been exporting grain in order to buy munitions, they have been devastating the country for two years with considerable success, they have terrorized productive industry with unquestionable thoroughness, they may have to stop their raids when hunger has camped on their trail, they may come to an agreement when it pays them to desist from fighting—not till then. Our information is that the whole border, from Nogales to Brownsville, is simmering with intrigue and outlawry, likely to provoke international complications any day. Americans and other foreigners are coming out of the mining centres, even in the North, from Mapimi, Parral, Chihuahua, for example. Everything is closed down at Guanajuato, for lack of supplies. El Oro and Pachuca are in the same plight. For a time the mines were allowed to be operated because they produced the bullion on which tribute could be levied by the various brigandages masquerading as governments.

Now the mines are to be despoiled. The mining operations heretofore persisting in northern Mexico, under the uncertain patronage of Pancho Villa, are now definitely at an end. That is about the only result of the A. B. C. and B. U. G. conferences. Meanwhile one significant incident may be recorded. The payment in silver made to the workers at Cananea has had the effect of drawing many from Villa's army. We believe that the establishment of a compromise government and the offer of *dos pesos por dia*, not in paper but in silver, to those joining a Federal army for policing the country would go far toward terminating a condition of chronic devastation. But to do that requires funds, not to be obtained without the recognition of our Government. No exterior Mexican loan can be made without such recognition. Amid the confusion of the last two years one result at least has emerged, and that is the financial suzerainty of the United States over the territory south of the Rio Grande. Through that power, exercised for the good of Mexico, without territorial aggression, and for the purpose of restoring order, will come a solution of the problem that has faced the Administration at Washington since the murder of Madero on February 22, 1913.

Ore-Stealing

The finding of $25,000 worth of gold ore in the possession of a man who was recently a 'specimen-boss' in the Empire mine, at Grass Valley, draws attention once more to the thieving that is half-condoned by being called 'high-grading.' As most of our readers are aware, in the mining of quartz veins that contain coarse gold, called 'specimen ore,' it is customary to detail trustworthy men to visit the stope-faces where such gold is visible and remove the rich ore in sacks. These men are called 'specimen-bosses.' In the case in question we have an example of confidence misplaced. One of the worst cases of ore-stealing at Cripple Creek was perpetrated in a similar manner, the foreman in the sorting-house being in collusion with a gang of thieves. The evil is as old as mining. So is the confusion between right and wrong that is at the basis of it. This form of petty larceny begins with the notion, among otherwise respectable miners, that there is no harm in pocketing an occasional specimen; just as there is a kind of tourist that thinks it not improper to purloin an occasional spoon as a souvenir. From a single specimen to a sack-full of rich ore is merely a matter of gradation. The Western miner who would regard a bullet as the proper sequel to the theft of a horse will smile at the stealing of enough gold to buy a herd of horses. The fallacy is ancient. In the records of Guanajuato we are told how Antonio Obregon built the church of Valenciana by persuading the miners to donate the ore they stole to this worthy cause, placing the larcenous portion of mineral on a quadrangular area especially set aside for the purpose. In later days we have the case of the alluvial gold mines of the Bodaibo, in Siberia, where the peculation of gold is officially recognized by the company operating the Lena Goldfields. In one year, namely 1913, the company paid $414,395 for gold stolen by its own employees. That sum of money, of course, did not represent anything like the full value of the gold. It was ransom. Owing to the isolation of the mines, the workmen are not able to get away with the gold, so that this regularization of theft is deemed expedient. In some gold-mining districts the stealing of ore has become a well organized business, aided by illicit buyers, unchecked by the police, and feebly condemned by the local courts of law. That is the story of Ballarat and Bendigo, of Cripple Creek and Goldfield, of Kalgoorlie and Grass Valley. The chief agent in the chain of criminality is the illicit buyer, disguised as an assayer or a sampling-works. The trade is lucrative. Those who try to stop it are hampered by a loose, if not perverted, public opinion creating a sneaking sympathy with the poor miner who takes his small share of the mine-owner's big profit. Besides such spurious sentiment there is the self-interest of the mining community. Those who make money in this nefarious business are prone to the spending of it freely in the saloons, gambling-houses, and other places. This helps local trade, while the gold that reaches the legitimate owner is likely to be spent far from the place of its origin. Hence convictions in local courts are difficult. In a notorious case at Cripple Creek, several years ago, a judge decided that the stealing of ore was not petty larceny because mineral was real estate. In that rich district the 'fences' or illicit buyers became so numerous in the bonanza days that many of the so-called assay-plants were dynamited, with the connivance of the mine-owners, during a period of labor disturbance. Thus one crime was perpetrated to check another. Indeed, the ineradicable lawlessness of undisciplined man is at the bottom of it all. The labor-unions wink at the evil. The public fails to see it in its true light and even forgets that it is not the miner, but the go-between or 'fence,' that makes most of the profit. Judges and juries are lenient, the punishment usually meted being quite inadequate as a deterrent. The idea that the stealing is done only in mines yielding big dividends serves as a sop to the feeble-minded moralist; but, as a matter of fact, much of the 'high-grading' is perpetrated in mines in which the average yield is low, although occasional rich spots in the vein or lode facilitate theft. The only cure is the recognition of facts and the discarding of an unhealthy sentimentality on the part of the public. What is needed is more respect for law and a better recognition of the distinction between *meum* and *tuum*. To effect that we must begin by calling things by their right names, replacing such euphemisms as 'high-grading' by 'theft,' and 'specimen-hunting' by 'stealing.' Whether it be a rich mine-owner or a small operator from whom gold is stolen, whether it be a hotel or a private house from which a silver spoon is purloined, the wrong done is equal, and no sophistry or sentimentality will change the fact. The wrong is not so much to the owner as to the community, whose code of conduct is flouted, whose sense of right is undermined.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Relative Error in Alluvial Sampling

The Editor:

Sir—Under the above heading Mr. Charles S. Haley published an article in your issue of July 17 dealing with the various sources of error to be considered in sampling gravel deposits by drilling or shaft-sinking. While agreeing with him in a large part of his statements, there are a few points, which should be of some importance, upon which I most emphatically disagree with him.

In discussing the measurement of the core when drilling with a Keystone drill, he says that it "is absolutely incompatible with making any speed" to measure each pumping, and further, that "the usual practice is to measure up only when the sluice-box begins to get full or nearly so. So you do not have the core that you should have for your drive, and you don't know how much of the core you have saved." In considering drilling with an Empire hand-drill, he says "the total core for the drive may readily be measured up and checked with the theoretical core without cutting down the speed of drilling. In this case, a flexible system of keeping the log is applicable such as is impossible in the case of the Keystone."

My first objection to Mr. Haley's article is that for an engineer who insists so strongly upon the use of judgment, he is strangely anxious to develop speed at the expense of accurate and dependable results. I have had considerable experience in the use of each of the drills mentioned, and in the light of that experience contend that it is possible to measure the core for each pumping with a Keystone drill without appreciably lessening the speed of drilling. Also that it is possible to apply to the Keystone any system of keeping the log that may be employed on the Empire. Moreover, because the volume of core is much greater in the case of the Keystone, instead of the chances for error in measurement being greater, they are actually smaller. This is one of the principal advantages which the power-drill possesses over the hand-drill, and is, I think, the prime reason why it is preferred by most engineers wherever its use is possible.

I shall describe, as briefly as possible, a method in use by which the core for each drive may be measured without necessarily sacrificing accuracy for speed, and also the method of calculation by which the core measurements may be used to correct the weighed amount of gold for the hole.

The pump is emptied, and washed, into a tight sluice-box that can be drained and washed, into a bucket set under the lower end. After settling for a moment in the bucket, the water is drained off through the rocker by the simple process of tipping the bucket to one side on the rocker-screen. A good bucket to use is the standard 16-quart galvanized iron bucket, the dimensions of which are: top diameter, $12\frac{3}{4}$ in.; bottom diameter, 9 in.; depth, $9\frac{1}{4}$ inches.

The water being drained off, a straight piece of wood is laid across the top of the bucket, and the distance is measured between the lower edge of the wood and the top of the pumped material in the bucket. The material is then rocked as usual and the gold is saved after counting the number of 'colors' of each size. After a little experience in any particular district, it is possible to have the panner divide practically all of the gold recovered into three sizes, called No. 1, 2, and 3, in such a manner that on an average ten No. 3 colors will approximately equal one No. 2 color, and ten No. 2 colors will likewise approximately equal one No. 1 color.

The material passes from the rocker into an accurate measuring box, of $\frac{1}{2}$ or 1 cu. ft. capacity, and the slime passing over is caught in a square hole where it is settled, so that all of the material washed can be measured and used as a check against the bucket-measurements.

The panner is now ready to note results. He first consults a prepared table, one column of which gives the depth by half or quarter inches from the top to the bottom of the bucket. In a column opposite is given the proportion of the material filling the bucket to any depth, as compared with the required core for one foot of drive. For instance, at $1\frac{1}{2}$ inches down the proportion is 1.44; at $4\frac{1}{2}$ inches down it is 0.78; and so forth. Of course these proportions are not absolutely correct; they depend upon the character of the ground drilled. There will be a large run-off of slime in clayey ground, and broken coarse gravel will measure more than sand for the same depth of drive. It does give a much more definite basis to work upon than the drive-shoe cross-section multiplied by the depth of drive, especially in tight ground where the actual pumping will sometimes be not more than one-third or a half the theoretical core, or in running sandy ground where the pumping is often several times too large.

After finishing a hole, the gold is amalgamated with as small a quantity of quicksilver as will readily take up all of the gold; it is then bottled, labeled, and turned in with the log to the engineer in charge. He dissolves the quicksilver with dilute nitric acid, then washes,

dries, anneals, and weighs the resulting clean gold, preferably getting the weight in milligrams.

The record for the bottom few feet of a purely imaginary drill-hole is given for purposes of illustration. Referring to it, we find that for the 28th foot in depth we have 0.3 too much core, the next two feet have the correct amount, while at 31 and 32 there is not enough core. For the remaining fraction of a foot there was obtained 0.8 of the correct amount of core for a 1-foot drive. Inasmuch as the drive was only 0.7 of a foot, the core-ratio is really 0.8 divided by 0.7, or 1.14. We may now calculate the correct weight of gold for the hole, as in the table below. The corrected colors column is obtained by dividing the core-ratio into the number of colors actually counted.

Depth.	Colors.	Core ratio.	Corrected colors.
28	10	1.30	7.7
29	15	1.00	15.0
30	30	1.00	30.0
31	60	0.90	66.6
32	75	0.67	111.8
32.7	170	1.14	149.1
	360		380.2

The corrected weight therefore is $\frac{380}{360}$ by 180 or 190 milligrams, and the value per cubic yard for the hole may be figured from this weight.

It is not claimed for this method that it will give absolutely accurate results. There are too many variable factors in the problem for that. For instance, the material in each foot driven usually swells to a different degree when broken into pieces of varying sizes; the amount of slime not measured will vary greatly with each individual foot; there is a large and inevitable personal factor in the estimation of the comparative sizes and counting of the colors; and so forth, indefinitely.

The method will, nevertheless, determine within narrow limits whether or not the proper amount of material is being extracted for each foot driven. If the operator does not care to go to the trouble of making calculations similar to those given for each hole, he at least has a double check upon the amount of material actually rocked, and a very fair idea as to whence it came.

Sloat, California, September 6.

Deflection of a Diamond-Drill Bore

The Editor:

Sir—I notice in your issue of September 4 an article on this subject by Ernest T. Preston. This article illustrates clearly the extent to which a drill-hole may deviate from the vertical and the importance of drill-hole surveys. It is much cheaper to survey a drill-hole at the time it is being drilled than to wait until later when a drill outfit has to be moved in especially for the survey and when there is sometimes difficulty in recovering the drill-hole. You may know of the trouble that the Indiana Mining Co. is having in the Copper Country of Michigan in finding underground a hole drilled from surface several years ago. Their shaft failed to find the ore where it was expected and a great deal of money has since been spent trying to find the drill-hole, without success. In this case, the standpipe from surface to lode had been pulled and as the depth is several hundred feet, it is impossible to recover the hole. A correct survey at the time the hole was drilled would have saved much money.

It is possible that the difficulty Mr. Preston had in getting his compass-readings to check was because the needle sometimes touched the side of the glass containing the jelly. I believe in the early compass-tests made in South Africa and Australia the needle was not protected in such a way that it could not touch the glass. The Cleveland-Cliffs Iron Co. has been using the Maas compass for this purpose since 1910 and has had no difficulty in getting accurate readings. This compass is also used by many other companies in Michigan that are now making a practice of surveying all their drill-holes. We find that inclined or flat holes often change direction and inclination just as rapidly as vertical holes. Since 1910, the Cleveland-Cliffs Iron Co. has made about 1000 separate tests for inclination and direction in drill-holes. Gelatin is used for the jelly and this has proven very satisfactory. We have tested holes to a depth of 2500 ft. by this method. Agar jelly would undoubtedly be an advantage when the drill-water is very warm, but in this country it is usually below 60° F. Under these conditions, Agar jelly would probably set too quickly.

E. E. White.

Ishpeming, Mich., September 9.

[We, and our readers, are much obliged to Mr. White, who is chief geologist to the Cleveland-Cliffs Iron Co., for this useful and timely information.—Editor.]

The Cost of Radium

The Editor:

Sir—On page 406 of your issue of September 11, it is stated that "The fact that the Bureau of Mines has reduced the cost of producing radium to $36,050 per grain of bromide will perhaps make a visit to the radium booths interesting." Assuming this statement to be correct, except for the supposedly typographical error, which substitutes "grain" for 'gram,' we are again subject to the skilful exaggeration which the Bureau used so successfully in its campaign against the radium-producers early last year. This statement, in connection with the fact that radium was selling for $120,000 per gram, is supposed to indicate either exorbitant profit for the so-called but mis-named radium Trust, or else very superior results by the metallurgists of the Bureau. Is either conclusion fully warranted? The price at which radium is sold is given in terms of the radium element, whereas the cost that you report is given in terms of the salt, radium bromide. In spite of the general use of the amount of the element as a standard in

measuring radium by those most familiar with the business, and most interested in disseminating precise information, many persist in using the obsolete basis of radium bromide, frequently not even taking the trouble to qualify the statements made by using bromide, but speaking only of radium, when radium bromide is intended. How long would we tolerate the use of the term lead instead of galena, for instance, by any intelligent and educated man? Yet an analogous situation with regard to radium goes almost unchallenged. Pure radium bromide ($RaBr_2.2H_2O$) contains 53.6% of radium element, which makes the cost of producing radium by the Bureau, when expressed in standard terms, $67,257 per gram, which is "something else again." Until the Bureau makes public the details that make up this cost in order that we judge as to whether the cost of developing the process has been properly included, and what other items are or are not included, we can hardly, in fairness, consider that it has made out a clear case in favor of its contention, when all the diverse factors entering into this delicate process are given full weight. Is the price of radium exorbitantly high for the product of a new industry?

L. O. Howard.

Salt Lake City, September 13.

Mining and Milling in Wisconsin

The Editor:

Sir—I wish to call your attention to an error, probably typographical, which occurs in your issue for September 4. In the article by Clarence A. Wright on 'Mining and Milling in Wisconsin,' it is stated that following the rolls there are trommels "with 1½-in. holes." Undoubtedly ½-in. holes was meant, for that is the usual opening for this district. In many mills $\frac{7}{16}$ and ⅜-in. holes are used, but in no case does a coarse 1½-in. feed go to the jigs.

Paul R. Fanning.

Platteville, September 14.

Publicity and Advertising

The Editor:

Sir—Without pretending to be an authority on the subject, I offer the following suggestions as to advertisements in technical journals apropos of your article on this subject. It would seem as though there were three legitimate purposes to a page or half-page advertisement. First, it is necessary to catch the eye. Secondly, there should be some information imparted for the benefit of the thoughtful reader. Thirdly, somewhere in the wording or picture should be a phrase, idea, or impression which will linger in the reader's mind.

Many advertisements appear to have achieved all they want if they merely catch the eye, and arrest a reader's attention for a second or two, without his exactly knowing what product is being advertised. Such advertisements may show a cannon or a duck or an aeroplane glaringly displayed. The reader looks at the cannon, duck, or aeroplane, yawns—and turns the page. Now, while such startling and thrilling pictures of such curious objects are mildly interesting, it is obvious that the writer of a technical article in the journal proper would never think of coaxing the reader's attention by such a method. While it is apparent that more leeway should be allowed an advertiser (of the Thomas W. Lawson type or otherwise) in spectacular display and license, it is rather beyond my ken just how an aeroplane helps to advertise, say, a mine-pump or a special brand of belting. I admit that a skilful journalist might consistently utilize an unusual or popular picture to draw attention to goods that really had some connection with the article in question, either in use or in appearance and name. For instance: butterflies and butterfly-valves. But in many cases such connection or similarity is so far-fetched and artificial as to approach the nature of a farce.

I have looked at an advertisement showing a photograph of a machine operating in Alaska, in South Africa, or in China, and been struck by the oddity or attractiveness of the scene. The next thought is "Why does not the company append a brief description of that particular job; certainly it would be interesting to read of what was done, and how it was accomplished, the difficulties, dangers, and ways-out that were part of the work?" Yet it usually happens that when an advertiser does add a description of work accomplished it is a bristling mass of formidable data so poorly arranged as to encourage the thought that the office-man who compiled it did not know what the figures meant.

It is my private but convinced opinion that the reason why technical advertisements display such a lack of brains is because the man who is deputed to write them has everything necessary except the brains. Like the editorials of some city newspapers, technical advertisements appear to fall to the lot of cub-writers who may know something someday but who are starting poorly. Considering the immense amount of money expended on advertising, the question arises as to why manufacturers and selling agencies do not appreciate the fact that a thousand dollars spent on advertising-space accomplishes many times more results when a hundred dollars worth of intellect is combined with it, than the same space plus a half-hour of a high-school boy's brain.

But it is not meant to imply that all technical advertisements are dull and poorly written, or that all advertising managers are shy of brains and understanding. Many advertisements are excellent; some advertising managers are keen discerning fellows who see clearly the point of view of the men at the mines. Allowance must be made for the fact that sitting at a desk in a New York office looking at sky-scraper roofs on a routine of eight hours a day is not the best condition for originality or spontaneously clear thinking. Working with a lead-pencil in a cramped room among numerous clerks and paraphernalia is not exactly conducive to sensing the atmosphere of the mines.

New York, September 18.

The Mining Engineer

By WILLIAM L. SAUNDERS

*It is said that the last words of William IV, on hearing the sound of cannon on the anniversary of the Battle of Waterloo, were: "That was a great day for England"; and so as the members of this Institute look out upon this great Exposition and see and hear what California, a mining state, has done in but little more than half a century, we may perhaps be pardoned for exclaiming with joy and pride: This is a great day for the Institute of Mining Engineers.

We are glad to be here, we are glad that we are alive; happy in the thrill of vitality which is quickened by California spirit and by the elixir of your glorious climate. On behalf of the Institute which I represent, I thank you for giving us this day. In thus honoring the Institute you are paying a tribute of regard and appreciation to the whole mining industry; to the lusty pioneer who blazed the trail and whose dry bones were the only monuments to mark the milestones of his progress; to the educated engineer and the capitalist whose skill and money were spent beneath the soil in daring efforts to release the hidden forces of Nature and put them to the service of mankind. You are paying tribute to the geologist, the chemist, and the metallurgist, for they, too, are mining engineers and members of this Institute.

I speak of California as a mining state; as such were you born. You received your baptism in the waters of the South fork of the American river when Marshall discovered gold at Sutter's mill in 1848. This was the beginning of the Golden Age for California and the world. The Golden Age means more than the age of gold; it is the age of progress, of prosperity and industrial renown and wealth; the age of railways and steamships, of manufacture of steam-engines, and of electricity, of the telephone, telegraph, the automobile, and the aeroplane. All these things were made possible—yes, they were initiated and installed—through means which were afforded by the mining industry. The mining engineer has multiplied and replenished the earth through subduing it; he has released those forces of nature which have been hidden through countless ages; he has through the science of metallurgy and chemistry made it economically possible to widen and enlarge to enormous proportions the use and influence of these forces. Look into the modern locomotive and steamship and we shall see that almost every pound of their vital structure is a product of the mines. The lathe that fashioned the shaft is itself a product of the mine, and it gets its power to turn from coal mined by machines which are themselves products of the mines. Lest you say to all this that the art of mining is as old as the hills; let me remind you of the fact that mining at low cost, mining low-grade ore, and doing these things on a large scale, and the art of reduction and treatment through metallurgy, are the accomplishments of the mining engineer of our time. This was the key which unlocked those forces which have been the impulse behind the great industrial progress of the world. This, too, has all been accomplished since the discovery of gold in California.

Let us review some of the facts of history. The first half of the nineteenth century was a period marked by little progress in industrial wealth. The world's output of gold from 1800 to 1835 varied from ten to fifteen millions of dollars annually. The yearly product of iron during this period was only between two and three million tons, coal less than fifty million tons, copper less than fifty million pounds. There were no transcontinental railways, no great steamships, no battleships, no factory system of manufacture, no large corporations. The total gold product of the United States during the period mentioned scarcely reached one million dollars annually. Beginning about the middle of the century, when California set the pace by adding in a single year fifty, and even eighty millions of dollars to the gold of the world, there followed a steady and increasing progress made in the output of iron, coal, and copper. Railway building progressed on almost parallel lines; so, too, did the deposits in the banks of the United States. It is of interest to note here that the American Institute of Mining Engineers got aboard in 1871 and thereafter shared closely in growth and prosperity this march of industrial progress.

The world's production of gold at the present time is over $450,000,000 annually. The United States alone now produces over 26,000,000 tons of pig-iron annually, and about 550,000,000 tons of coal. The world's yearly production of copper is now over 900,000 tons, and of this the United States produces over 500,000 tons. So, too, we find that the average per capita wealth of the people of the United States has risen from $300 in 1850 to over $1300. The influence of mining on wealth is conspicuously shown in the case of your neighbor, the State of Nevada, where the per capita wealth of her people is about $4800. Nevada is, strictly speaking, a mining state, with easy divorce laws to interest and allure the homeless and distracted mining engineer.

California has added more than $1,600,000,000 to the gold supply of the world. Her record average of over $25,000,000 in gold annually for 50 years is unprecedented. It has been estimated that the actual value of

*Address delivered by the President of the American Institute of Mining Engineers, Panama-Pacific Exposition, San Francisco, September 17, 1915.

gold deposits should be multiplied eight times to get the true value in credit and capital: If this is true, then California has in her gold supply alone contributed over $12,000,000,000 to the capital wealth of the United States.

Gold is the standard of all values. It is the measure of credit, the basis of exchange. "Change and decay on all around I see," but in gold there is no change, no decay. The lure of gold has discovered continents and turned deserts into fertile lands. Gold was the beacon-light which led Columbus across the Atlantic. Cortez, Pizarro, Balboa, and others who are called explorers were really pioneers and prospectors whose voyages led to the early development of mining in Peru and Chile. But not till California led the way did the mine explorer become a world builder; he was the advance agent of prosperity.

The stability of this country in peace and in war is due mainly to the mining engineer. Our industrial strength comes from the mines, the mills, and the furnaces which are now so well organized on a peace basis and which have in their substance all the sinews of war. Military supremacy comes from the same elements as industrial supremacy: It is mainly a question of organizing the resources of the country. Of one thing we may feel sure and that is that no nation can ever make a scrap of paper out of a gold eagle.

> You may crush, you may shatter the coin if you will,
> But the value of gold-dust remains with it still.

It was because of the recognized importance of the mining and metallurgical industry that the American Institute of Mining Engineers was organized at Wilkes-Barre, Pa., in 1871. Following the War of the Rebellion and coincident with the development of the mining industry in the far western states, there arose a great demand for mining engineers. It was recognized that the chief factor in the development of the Western country was the mining industry: It created a romantic interest and it gave a stimulus to the people in general and even to Congress, which granted large subsidies for railway building. Scientific schools were established and technical journals disseminated engineering literature; but the mining men, those actually engaged in the mines and mills and smelters, were not organized: They needed a common ground for the exchange of ideas, a forum for discussion and education; and so the Institute was established. It was the second society of its kind following the organization of the American Society of Civil Engineers. The Transactions of the Institute cover geology, assaying, milling, smelting, mining, quarrying, and general construction management. The papers submitted at the meetings cover a wide field and are recognized by engineers and scientists throughout the world as of significance and value.

The Institute is incorporated under the laws of the State of New York, organized and existing with the object of promoting the arts and sciences connected with the economic production of the useful minerals and metals and the welfare of those employed in these industries by means of meetings for social intercourse and the reading and discussion of professional papers, and to circulate by means of publications among its members the information thus obtained. Its membership includes those who have worked their way up from the ranks as well as graduates from scientific schools and colleges. Leading professors and technical educators have always been prominent in its membership. The welfare and safety of the mine-workers is a subject of recent and earnest interest among the members, and a new field of usefulness has been developed in using the power and the influence of the Institute wherever the industry represented by mining and metallurgy or the people engaged in the work may be benefitted through state or national legislation.

On behalf of the members of the American Institute of Mining Engineers, numbering now over 5000 and scattered throughout the world, I extend to President Moore, to San Francisco and to California, a full measure of warm congratulations and our best wishes for continued and increasing health, happiness, and prosperity.

Canada is practically the sole producer of cobalt ore; the cobalt content of the ores mined in the Temiskaming district, Ontario, exceeds 2,000,000 lb. per year. The market for this, at present, depends altogether on its limited use as a blue coloring substance. Hence there is a large accumulation of cobalt oxide at the smelters and at Cobalt. Under present industrial conditions, the smelters refuse to pay for the cobalt and nickel content; consequently, the miner receives nothing for this valuable constituent of the ore. Yet the metal cobalt resembles nickel in almost all its properties. Its density, malleability, ductility, hardness, tensile strength, and electrical properties are, so far as they are known, very similar to those of nickel. These properties of nickel make it of remarkable industrial value in the composition of a great variety of alloys. Of these may be mentioned the high-grade steels, where toughness and hardness are desired: for automobile parts, steel tubes, gun steel, cranks and crank-shafts, boiler-plates, tires, connecting-rods and axles; the nickel-iron wires such as 'invar' and 'platinite,' with low temperature coefficients of electrical resistance and of expansion respectively; and the variety of important nickel alloys with non-corrosive properties, for coins, boat propellers, etc. It would be surprising if cobalt could not be advantageously substituted for nickel to produce a better grade of some of the above products. As these are high-grade products, where superior qualities are desired, a high cost, within certain limits, would not be prohibitive. Hence, if research leads to the substitution of cobalt for nickel, even in the case of one of these products, a market for the metal cobalt at a reasonable price would be assured, and large sums of money would be annually added to the returns from Canadian natural resources.

Danish pebbles are considered the most economical of all tried at the Tonopah-Belmont mill.

The Cornish Miner in America

By P. B. McDONALD

Three or four miles southwest of Ishpeming, on the Marquette Iron Range, is the old Saginaw mine, idle now for 35 years. Once it was a lively producer, but the hard-ore 'vein' pinched out, and the old place looks a wreck. During the long period of neglect, various 'squatters' settled on portions of the extensive property and acquired little farms. A few years ago, when the attention of mining men on the Iron Ranges was being directed toward finding soft-ore concentrations in the lower horizons of the iron formation, the company by which I was employed bought the old Saginaw mine. I was sent to the mine on a surveying and geological reconnaissance. The most likely place to stay appeared to be at the self-appointed watchman's cottage, where lived 'Garge' Blee, a little Cornishman of some local reputation, who had worked in the mine forty years before. He was a character. With his wife he had resided at 'the Corners' for years, and he was familiar with all the history of the mine—except the essential points I wanted to know, which he had forgotten. But he overflowed with anecdotes, reminiscences, and dialect —mostly dialect. He was so typically a Cornishman and 'Cousin Jack' that he put all the others I had seen in the shade. His *pièce de résistance* in the conversational line was the recounting of his extraordinary exploits as a wrestler in the Cornish style when he had been young and his joints supple. According to his way of telling it, he must have been *some* wrestler in his day, having apparently "throwed" every Tom, Dick, and Harry in the Michigan mines. I particularly remember his account of how he overcame a great bully of twice his size by catching him on a slippery path and heaving him over his head with the 'flying mare' (" 'eaved 'im hover my 'ead," he said) so that the big fellow came down powerful hard on his ear and the back of his neck.

The old man could tell strange tales of early days at the iron mines; of gigantic air-blasts underground that blew the miners over like nine-pins; of marvelous driving accomplishments on contract when he and his partners reaped rich gains from their prowess at swinging hammers and twisting drills, being able to hit left-handed, right-handed, or in tight corners where modern miners could not operate; of terrifying shaft-sinking jobs when dire catastrophes happened daily; of cave-ins, falls of ground, floods of quicksand, mine-fires; of how the bottom of a river dropped into a stope and drowned the miners; of losing the 'vein' and how he (Garge Blee) found it again, when the whole mine-force was nonplussed; of famous old miners and foremen, Captain Bill Oliver, Captain Dick Trebilcock, and Captain 'Arry; of queer incidents and complications at the mines, that were all the queerer in his telling of them; of how a famous old captain in the copper country once paid his men off in native copper when the money for the pay-roll failed to arrive and the miners called for their wages.

Blee's little farm had the characteristic disorder of a Cornish homestead. He kept a horse (an 'arse he called it) a cow, a pig, chickens, ducks, guinea-hens, and several other species. I pleased the old man by taking his picture surrounded by his eight or ten dogs, and again one evening when he was milking his cow. He talked a whole day of how a neighboring farmer was threatening to sue the company for the loss of a bullock that had fallen into an old exploration-shaft, but he proved (by showing me the shaft) that the offended farmer must have "pushed the bullock in." One of the squatters, the most "no account" of them all, was named Sam Bennetts. This shiftless man was very proud of his dozen young sons, who were growing up some way, in spite of scarcity in the flour-barrel and of salt-pork at Sam's house. He was proudest of one who was away at the Reform School, which the father considered in the light of a college education. There were two reasons why Bennetts had never written to his absent son; he had lost the newspaper giving the account of the matter with the address of the reformatory and he never had had a stamp.

Cornish miners have a remarkably thorough understanding of mining. They are not in the business until they can get something better to do, nor as dilettanti, nor half-heartedly, but as men who take mining and underground-work seriously. They are as much at home in a dark 'scrambly' old stope, or at the face of some interminable drift, or in a stuffy underground pump-room, as a machinist in a machine-shop. They know underground things instinctively and look upon mining as a natural calling, much as a sailor looks upon the sea. Some superintendents do not like Cornish miners, saying that they are headstrong (which is true) and disputatious (which may also be true). But, when properly handled, as at certain mines in the Lake Superior region, Cornishmen make very steady, satisfactory, and capable miners. They are not so docile as southern or eastern Europeans, but they know more, are dependable, and are ingenious and go-ahead workmen.

There are a good many Cornish miners and foremen (or mining captains) both on the Iron Ranges and in the copper country. The numerous and ingenious stoping methods evolved in the Lake Superior mines (whereby shoveling is nearly obviated, timber is diminished, and safety and ease of handling the ore are strikingly attained) have been largely due to the underground ability and understanding of the Cornishmen. It is an innate Cornish principle to use one's head in mining; hence the labor-saving systems by which ore is stoped down in large masses to fall directly into chutes for loading into tram-cars. From the Lake Superior region, Cornish miners and their praiseworthy mining methods have spread to all the districts of the West. It is also interesting to note that from the ancient tin mines of England's southwest corner, Cornishmen have followed the call of the pick and drill to the ends of the earth—South Africa, Australia, America, East, West, North, and South.

LOADING WITH HORSES AND SCRAPERS.

TRAIN OF ORE-CARS.

Mill of the Big Four Exploration Co., Utah

By L. O. HOWARD

Introductory. For many years the accumulation of various tailings in the Park City district, Utah, has held interesting possibilities. All the mills of the district have been situated at Park City or in the canyons south of the town. Tailings have been distributed over a distance of at least nine or ten miles. In the two miles of steep canyon above the town there has been little accumulation. Just below, however, is a flat on which a small amount has collected, and been subjected to re-treatment. A mile below the town in Silver gulch is a large accumulation now the object of treatment by the Broadwater Mills Co. in a 500-ton wet concentration and flotation mill, at present under construction. It is estimated that 450,000 tons is available here. Farther down the canyon are several smaller accumulations in the flats where smaller plants are at work. Seven miles below Park City, at Atkinson, is the deposit now being exploited by the Big Four Exploration Company.

In the earlier days of milling in the district little attempt was made to save the zinc minerals, and even as late as 1913, recoveries of zinc were low. Only now are they at the point of being bettered. For instance, weights and assays published in the report of the Daly West Mining Co. for 1913, this company being the only one of the three large operators to publish the assay of the second-class ore fed to the mill, indicate a recovery in marketable form of only 22% of the zinc in the ore. It is doubtful if others are doing much better. Making due allowance for the zinc contained in lead concentrate, and hence not available for operators on tailing, and for the fact that previous to the impounding of tailing in recent years, the zinc in tailing has run progressively higher the nearer we approach the early days of milling, it is evident that the accumulation of tailings for many years has resulted in a product that is attractive for its zinc content.

The milling-ore has consisted of galena, pyrite, chalcopyrite, and sphalerite in a quartz gangue, the lead, copper, and iron sulphides containing a large proportion of silver and some gold. Prior to the last decade the problem in concentrating has been "to save the galena and pyrite, together with any chalcopyrite and tetrahedrite which may be present and to throw out silica and all the zinc-blende in excess of the allowance."* The first mills, built in 1874, were stamp-mills. In 1875 four

*Professional Paper No. 77, U. S. Geol. Survey, page 27.

MILL AND TRANSFORMER STATION, AT ATKINSON, UTAH.

mills, using 80 stamps, were running. In 1877, at the Ontario mill, the ore was dry-crushed, given a chloridizing-roasting, and amalgamated in pans. In the early 'eighties the Russell lixiviation process was developed, from which there was, of course, but little sulphide tailing. In 1878 the first concentrating machine—the McKim—was put in operation in a mill near the Marsac, in the city limits. This machine had some resemblance to the early Frue vanners, which later were used here. In 1889 the first modern concentration plant was erected and wet concentration has since been the general practice, with the exception of the brief periods in which magnetic separation, dry table-separation, and the more recent chloridizing-roasting and leaching process, were in vogue.

Zinc was not as prominent a constituent of the ore in the upper workings as it soon became in the deeper stopes, especially in the fissure type of deposit. In the 'nineties the zinc problem was first recognized. In the concentrating ores zinc was present in amounts from 6 to 10%. With a specific gravity near 4, in an ore containing pyrite of specific gravity 5, galena of specific gravity 7.5, and chalcopyrite of specific gravity 4.1 to 4.3, difficulty was inevitable in making a satisfactory saving of the zinc.

There are now at least six plants, large and small, treating the tailing from the Park City mills, in wet-concentration plants. Part of these treat current tailing, namely two above the town, which make a good recovery of zinc and lead on Wilfley tables in simple little plants. Below the town I observed four plants in operation on accumulated tailing, producing remarkably good-looking lead and zinc concentrates. Shipments from all these amount to 500 tons monthly.

The Ore. The portion of these tailings, now so thoroughly mixed as to be fittingly labeled 'tailing,' that is under lease to the Big Four Exploration Co., lies seven miles below Park City at Atkinson. It covers an area 3½ miles long, and 500 ft. wide. The depth averages 2 ft. The amount available for milling is estimated at over 1,000,000 tons. Samples taken every 100 ft. along the flat indicate that the average metal-content of the tailing is as follows: Lead 1.8%; zinc 4.1%; silver 3.1 oz. per ton; gold 30 cents per ton; iron 2.5%. The silica amounts to 62%.

At present the tailing is being drawn into heaps beside an industrial railway by the use of eight or ten teams with scrapers. From these heaps the tailing is scraped over a plank-way bridging the tracks and dumped into 4-ton contractor-cars. Trains of four cars are hauled one mile to the mill by a 'jitney,' a converted 1911 Cadillac touring-car provided with flanged car-wheels, at the rate of 8 to 12 trips per 9-hour shift. The return trip now consumes much unnecessary time, since the car is only capable of the usual reverse speed. This drawback will be eliminated by the addition of a reverse gear that will permit the same speed backward as forward.

Upon arrival at the mill the cars are spotted over a 6 by 7-ft. grizzly having 4-in. spaces between bars, which are 2½ in. deep and ⅝ in. thick. All coarse foreign matter, such as wood, boulders, etc., is here removed.

The tailing falls into a pocket, 6 by 7 by 4½ ft., made of $\frac{3}{16}$-in. steel plate, which feeds a 16-in. belt-conveyor. This carries it 140 ft. up an incline of 24° to the top and far end of the mill. The belt travels at a speed of 206 ft. per min. In Fig. 4 the unloading-shed is shown at the extreme left, connected with the mill-building by the conveyor-shed.

Flow-Sheet. The mill-building is 73 ft. long and 56 ft. wide by 40 ft. high, of frame construction, covered with tarred paper. The site is flat, requiring the use of five elevators. There are four main floors. At the top are the waste-trommel, distributing belt, and waste-belt. On the third floor are the jig-trommel and Callow screen. On the second are four roughing Wilfley tables, two coarse and two fine jigs. On the bottom floor are two finishing Wilfleys for concentrate and five for middling and the re-grinding mill. In a tower on the roof is the water-supply tank.

The tailing is discharged from the incline conveyor to a waste-trommel, 4 by 6 ft., covered with double-crimped wire-cloth screen having ½-in. apertures. Screening is done dry, all material over ½-inch in size being discarded to an 11-in. reject-conveyor, running over a trestle outside the mill to a waste-dump.

The undersize of the ½-inch screen falls upon a 14-in. distributing belt which delivers to a V-bottom storage-bin, 12 by 32 ft., by 16 ft. deep, having a capacity of 4600 cubic feet, or enough for four or five shifts. This bin is filled in one 9-hour shift.

In order to avoid being impaled upon either the ambiguous or the prolix horn of the dilemma, it becomes necessary at this point to clarify our use of terms. 'Ore' will be used when referring to the untreated tailing that is the object of milling, reserving 'tailing' for the waste-product of machines or of the mill as a whole.†

The ore is drawn from the bin, with the aid of a stream of water, to the boot of the main elevator, by which it is lifted 30 ft. to another trommel, 3 by 6 ft., covered with double-crimped wire-cloth screen having ¼-in. apertures. Below the trommel is a 16-mesh Callow screen. Three sizes are thus made for the primary concentration, as follows: through ½-in., on ¼-in., through ¼-in., on 16 mesh; through 16 mesh. The coarse is treated on two 3-compartment Harz jigs, and the medium on two others. Jig-screens are 17 by 32-in. double-crimped wire-cloth, 8-mesh on the coarse and 10-mesh on the fine. Both sets of jigs are used as roughers, making a large amount of low-grade concentrate from hutches and side-draws, and sending the tailing to the creek. The jigs are old equipment brought from Idaho and have not worked satisfactorily. Nothing about them appears to be right. A heavy vibration is set up, eccentrics bind, beds do not form properly, boils are constant, and hand-skimming of the bed is necessary every 15 minutes. A few days' operation of the mill has shown the necessity for new jigs, and they are to be erected.

The fine is also subjected to a roughing treatment on

†[This is quite correct. The old 'tailing' becomes crude ore to the man who is treating it *de novo*.—Editor.]

four Wilfley tables. These discard tailing to the creek and make a mixed concentrate, which is treated on two Wilfleys for a lead and a zinc concentrate, and a middling, which is combined with the middling from the roughing tables.

The middling from the jigs is settled in two superimposed boxes, the coarsest and heaviest portion being re-ground in a No. 43 Marcy ball-mill. The overflow from the first box is by-passed around the mill; the overflow from the second goes to the main elevator and re-enters the circuit.

The discharge from the ball-mill is passed over a 10-mesh screen and the oversize returned to the main elevator to re-enter the screening section.

The re-ground jig-middling that passed 10-mesh, the middling from the roughing and finishing tables, and drainage from the concentrate bins are elevated to a 6-spigot hydraulic classifier having compartments of equal width, but progressively increasing length and depth. This classifier prepares the feed for five Wilfley tables, each of the first five spigots feeding a table. A sixth table is to be erected immediately to treat the sixth-spigot or slime material, part of which is now drawn off in spigot No. 5, and part of which goes off with the overflow to the creek.

All of these Wilfleys make similar products: finished lead concentrate, finished zinc concentrate, finished tailing, and a middling composed largely of poorly sorted grains, which is returned to the classifier.

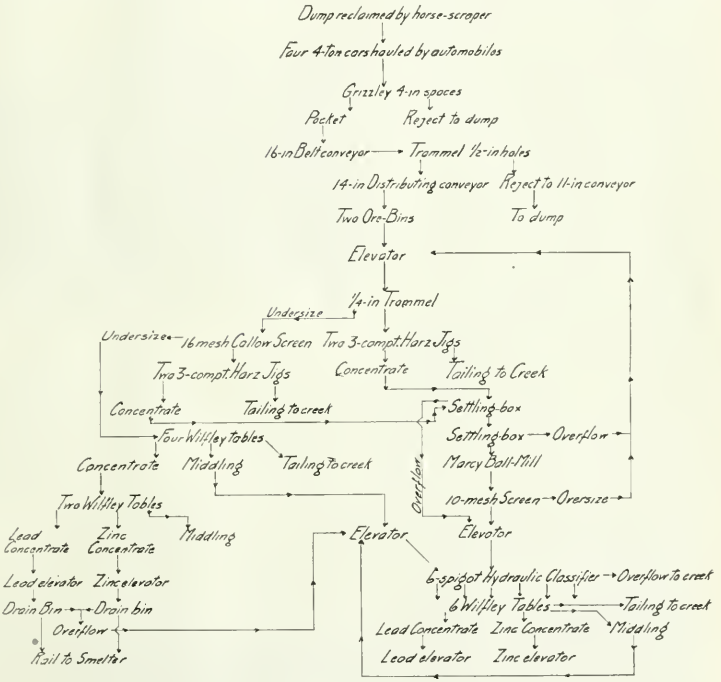
The process of treatment thus consists of a preliminary removal of dry waste on grizzly and trommel, and sizing for three products that receive a roughing treatment on jigs and tables, the bulk of the tailing being rejected as soon as possible. Only the fine concentrate is at once cleaned. The coarse low-grade concentrate is re-ground and with the fine from the preliminary screening is classified with hydraulic water, for the final table-separation.

EQUIPMENT. Some of the equipment has been brought to this mill from other plants and some is new. The old equipment, with the sole exception of the jigs, is giving satisfaction.

The Wilfley tables used for roughing are three of No. 5 type and one No. 6. The No. 6 and one No. 5 have the usual riffling. The other two have an improved riffling. On one the four lower riffles extend to the end of the table parallel with its motion. The remaining riffles are given an upward slope toward the feed side of two inches in nine inches, to a diagonal termination, the upper riffle being four feet long. Every alternate sloping riffle is brought out 22 inches, parallel with the feed side, to a second diagonal termination.

The other roughing-table has a similar riffle except that the end portions parallel with the feed side are brought out the full length of the table. This is the regular No. 10 riffling. These improvements have resulted in a greatly increased capacity.

Among the remaining tables all three types of riffling are represented. In addition a fourth type, known as the Thompson riffle, is used. This is the same as the standard



FLOW-SHEET OF BIG FOUR OPERATIONS.

riffle, except that every alternate riffle is cut off a few inches, forming two parallel diagonal terminations. It is evident that the No. 10 riffle is well suited to the production of clean tailing and a large amount of low-grade concentrate, whereas the Thompson riffle will give a cleaner concentrate than the usual riffle, and take care of losses of mineral by returning a small middling.

Wash and cleaning water are applied to the tables through the usual box fed by separate pipes connected to an overhead line. The finishing Wilfleys are both No. 5; the Wilfleys treating re-ground jig-middling are three No. 6 and two No. 5.

The Marcy ball-mill is of the size known as No. 43. It is 4 ft. in diameter and 26 in. long. It is driven at 32 r.p.m. The lining is of the Krupp type. Crushing is done by steel balls varying in diameter from 1 to 3 inches. Feeding is by scoop-feeder. The discharge is

through a grid of the same diameter as the mill. On the jig-middling the capacity has not been definitely determined, but with proper jigging it is expected that it will handle all provided the fine material is by-passed and the portion of middling formed by any clean particles of quartz that should go into the jig-tailing is kept out of the mill. It does not finish all the product to the desired size, however, and a 10-mesh screen has been attached to the discharge end to return the oversize to the preliminary screening section.

Five elevators are used. The main elevator has a lift of 30 ft. It receives the ore from the bin and oversize from the ball-mill. Re-ground middling is lifted 20 ft. to the classifier by a second elevator. All table-middling and drainage from the concentrate-bin goes to a third elevator having a 30-ft. lift to the classifier. Both the concentrate-elevators have a lift of 30 feet.

Power and Labor. The mill is driven electrically. Current is taken at 54,000 volts from the lines of the Utah Power & Light Co., and is transformed at a substation at the mill to 11,000 volts. It is then reduced to 440 volts in smaller transformers. Only two motors are used, both 3-phase 60-cycle. One, of the Westinghouse make, drives all the machinery of the mill proper. It delivers 40 hp. at 1160 r.p.m.

Power is distributed through five line-shafts. No. 1 shaft drives the ball-mill through a belt, counter-shaft, and gears. It also drives No. 2 shaft, which drives the four roughing Wilfleys and No. 3 shaft. No. 3 shaft drives 4 jigs, the main elevator, and the jig-trommel through two counters and a bevel-gear. It also drives the counter-shaft of the Callow screen. No. 4 line-shaft takes power from No. 2, and drives the remaining four elevators, five Wilfleys, and a counter-shaft from which the concentrate-finishing Wilfleys are driven.

The other motor, a 15-hp. Allis-Chalmers, running at 1150 r.p.m., drives a line-shaft, from which the incline-conveyor is driven by gears, the reject-conveyor by belt, and the waste-trommel by belt, counter-shaft, and gears. This last counter also drives the distributing conveyor.

Thus there are two power-units, one driving the equipment for loading the ore into the mill-bin, the other driving the mill. On the latter drive there is, of necessity, much line-shafting, belting, many loose and tight pulleys, and troublesome clutches. Most of the transmission is well out of the way, allowing good lighting of the mill. It is worthy of note that all dangerous places, near which mill-men must pass on their duties, are protected by railings to promote safety.

Water is taken from a sump in the creek by a triplex pump having a capacity of 300 gal. per minute, and is lifted to the supply-tank at the top of the mill.

While the mill is being tuned up, 5 men are employed per shift. When running smoothly, it will require a jig-man and a table-man per shift, and a conveyor-man on one 9-hour shift.

Results. Concentrate from the tables drops into launders through which it flows to the boots of two elevators, one for lead concentrate and one for zinc concentrate. Each elevator discharges to one of a pair of bins, each 5 ft. 8 in. by 9 ft. 4 in. by 7 ft. 2 in., provided with filters of screen and burlap. During filling the bin drains, and concentrate is allowed to stand in it until the other bin is nearly full. Then the first bin is emptied through bottom gates to tram-cars, by which the concentrate is taken to railroad-cars on a spur of the Union Pacific railway beside the mill. Tests have indicated that the assay of concentrate will be as follows:

	Zinc Concentrate	Lead Concentrate
Zinc, %	39	..
Lead, "	4.4	14
Iron, "	7.8	39
Lime, "	2.7	..
Silica,"	8.6	4
Silver, oz. per ton	7.04	11
Gold, " " "	0.02	0.07

The mill was started on July 20, on one shift. A second shift was added on August 2, and a third on August 3. At the time of my visit, on August 13, it had not got into its stride; shut-downs were frequent for necessary tightening of belts and bolts, alignment of shafting and pulleys, and, in short, the treatment of the usual ailments of a new mill. Actual results of operation, therefore, are not available, but an estimate of recovery based on tests conducted by the designers of the mill, checked by past experience on similar material, is as follows: 40% of the lead, zinc, and silver, with 25% of the gold. By the addition of flotation treatment, the recovery of zinc could be raised to nearly 70%. Flotation is not to be added for the present.

It is planned to increase the capacity of the plant by the addition of four Wilfley tables and another trommel. When operating at 200 tons per day there should be produced daily 10 tons of lead concentrate and 8½ tons of zinc concentrate.

It is also planned to use a drag-line excavator for piling the tailing near the track.

No cost data are as yet available, but it would appear that the cost of reclaiming the tailing and putting it through the mill should be low, with promise of a fair profit from the operation.

The mill was designed by Kirk & Leavell of Salt Lake City, and is operated under the supervision of M. P. Kirk, with Jack Sweat acting as foreman. To these men is due an acknowledgment of generous aid in obtaining data for this article, in the midst of the unsettled conditions attendant upon 'tuning up' a new plant.

Awaruite, a variety of nickel-iron, consisting of 67.93% Ni, 0.70 Co, and 31.02 Fe, has been detected as a primary constituent in peridotite on the west coast of New Zealand. In the river-beds of Josephine and Jackson counties, Oregon, boulders of a nickeliferous iron up to 100 lb. in weight have been found. This has a composition very nearly Fe_2N_5, while awaruite is Ni_2Fe. The large blocks of nickeliferous iron of Uvifak, on the island of Disko, Greenland, weighing 25 tons, occur on a basalt sheet. Masses of iron, said by the Chinese to be three miles long, are reported from the Province of Szechuan, China.

Tramming Sand-Tailing

By JESSE SIMMONS

Disposal of sand-tailing is always a problem presenting more or less serious aspects, especially when conditions are such that sluicing is prohibited. At the Wasp No. 2 mill, at Flatiron, South Dakota, sluicing is precluded. A railway-track skirts the foot of the hill on which the plant is situated, and Whitewood creek, paralleling the railway, must not be polluted.

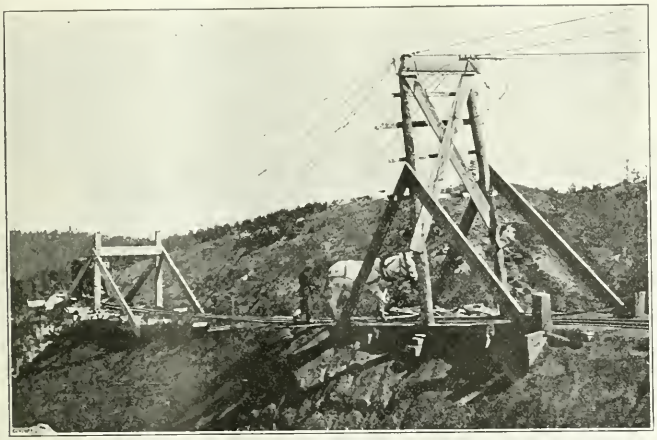


Fig. 1.

Tramming of the tailing has been the means of disposal always followed except for a short trial of belt-conveyors. These were highly unsatisfactory, especially in winter, when the damp tailing froze to them. Tramming, too, was unsatisfactory, chiefly owing to the tracks settling each night; this was particularly pronounced during the rainy season, and in the spring when the frost was leaving the dump. On such occasions the tracks would often settle three or four feet during a day, and it was necessary to use great quantities of timber. Eventually it became apparent, as the dump was extended, that the cost of timber would become prohibitive, so other means of supporting the tracks were sought.

The present plan, which works to perfection, is to support the tracks by means of wire ropes, one end of which is fastened to 'dead men' in the ground near the mill. They are passed over towers and attached to the framework on which the track is built. Fig. 2 shows the three tracks, supported in this manner. It will be noted that beyond the towers the tracks are in the air. The dump contains over a million tons of tailing, and it is constantly settling. After a heavy rain the settling is particularly noticeable; tracks that a few hours previous were apparently resting on the tailing, will be several feet above it.

It will be noted that the gradient of the track is upward, after passing the towers. From the loading-point, under the leaching-tank, it is downhill to the towers. A loaded car runs to the end of the track by the momentum it gathers in coming down the grade to the tower; it then returns to the tower, where the mule is hitched on, and the return trip to the loading point is made. The entire operation is smoothly and quickly done. The cars hold 2500 lb. of tailing; they are of the side-dump pattern, and discharge their contents quickly upon throwing a lever. One trammer rides the car to the end of the dump; his duty is to unload the car. Fig. 1 shows the car about to be dumped, and the mule being put in position to be hitched to the car upon its return to the tower. In Fig. 2 may be seen a few odds and ends of timber sticking out of the dump; it was formerly used by the trainload.

Each leaching-tank in the mill is provided with two bottom-discharge gates; each of the three tracks serves two tanks. The dump-car is filled by shoveling, or scooping with shovels, the tailing through the discharge-hole into the car standing immediately below. Edward Manion, the superintendent, who devised and installed the system, states that by its use the cost of tailing disposal has been reduced to 4½ cents per ton. As the gross value of the Wasp No. 2 ore is only about $1.80 per ton the saving is 2½ per cent.

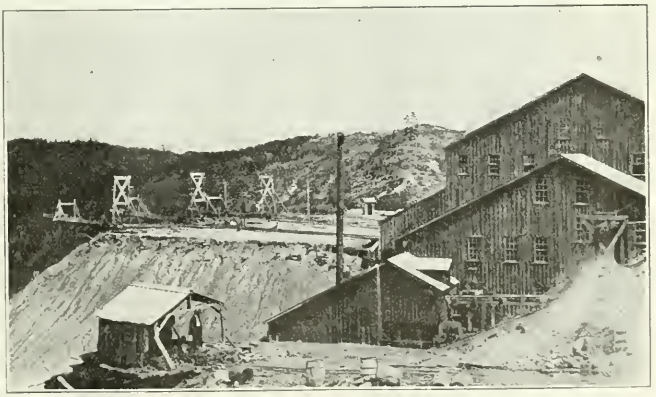

Fig. 2.

The Application of Efficiency Principles

By FRED H. RINDGE, Jr.

The skill with which 'Efficiency' is applied—what shall determine it? Does any system absolutely insure efficiency? Can an 'engineer' make men efficient? Are there other factors not generally recognized in the usual 'efficiency plan'?

In a booklet called 'The Profit Sharing Plan of the Ford Motor Company' I have just read "Man is largely a creature of environment. His interest in his work, his efficiency at his work, his loyalty toward his employer depend largely upon his surroundings during working hours. Light, ventilation, sanitation—all factors of health and efficiency—are given prime consideration. The approximately 15,000 workers at the Highland Park factory are taught to be clean and healthy—and so efficient." Surely these things are factors, but are they the only factors? Evidently the Ford company does not think so, for one of the instruction sheets issued to the special investigators reads: "We must know through you positively as to the conduct of employees outside of business, the extent of their indulgences that make for good or bad manhood.* * * The home conditions particularly, are of vital importance." Illustrations from other companies might be given.

Can it be true that such things as home conditions and the conduct of employees outside business have any relation to efficiency? And that phrase "good or bad manhood," what has that to do with efficiency? Has it a character basis? Is Big Business becoming concerned about these things that not many years ago would have been considered none of the employer's affairs? There may be some question as to just how far a company is justified in prying into such matters—it depends, I suppose, on how the investigator behaves himself. But there can be no question about the successful employer being vitally interested, for these things are all factors of efficiency. Anything that can magnify their importance and that especially can improve the character of employees will tend to increase their usefulness.

But this is only one side of the question. How about the man higher up—the foreman, superintendent, engineer, manager, president? He is the man who, other factors permitting, will determine the success with which 'efficiency' is applied. How can he best determine it? Shall he drive men or lead them; shall he get all he can or give all he can; shall he apply scientific management principles regardless of the men or because of the men; shall he use 'efficiency' for his own interest or for that of his employees as well; shall he use motion study, time study, and business organization to grind men down or to lift men up? In short, shall he be a man of self-interest or a man of social interest and a man of character? Can it be true that anything which improves the character of employees will tend to increase their efficiency also, and through them the results of the system as a whole?

From a purely business standpoint it looks as though the factors conducing to efficiency are numerous and complex, that they are determined by both employer and employee, and that they can be resolved into a character basis. It may be objected that many men are effective in business yet lacking in character, but the keen efficiency expert would question whether those men are as effective as they could be, and ought to be. Would they not be much more useful if they were men of character, and will they and their business 'win' in the long run? Business is increasingly a "survival of the fittest," but who in the long run is the fittest?

Many of these ideas are splendidly brought out in a paper read at the last annual meeting of the American Society of Mechanical Engineers:

"The development and application of the highest types of industrial management, is going to be difficult and delicate work, if the results are to be made a permanent benefit to society as a whole. Those who personally direct this development will largely determine the efficiency with which efficiency itself is applied. If the attempt is made by those in charge to seize all the benefit of improved methods and to crowd the advantage of the employer they will either defeat or indefinitely postpone the advance. They must be experienced men, wise, fair, thoroughly conversant with possibilities and free from sentimental idealism. This means not only a knowledge of machinery, systems, and time study, but of human nature and the rights and real needs of industrial workers.

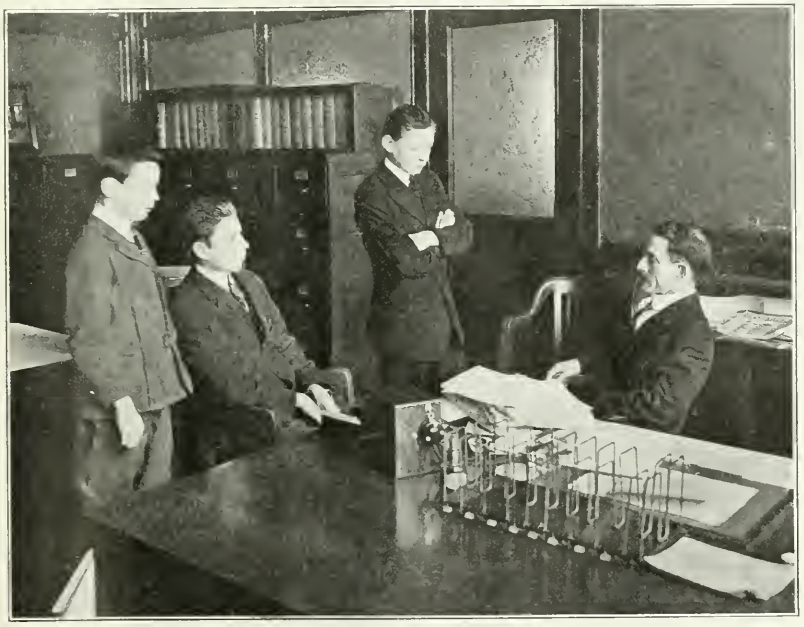
"The executive engineer will be at the focus of this situation. He alone is in direct personal contact with the two great elements involved; capital and labor. His thorough understanding of both of these forces will prove one of the greatest elements in progress. If the man in actual charge has little knowledge of, or sympathy with, the workman, serious missteps are certain. If, on the other hand, to a thorough technical training and knowledge of the resources and responsibilities of the employer, he adds an attitude of fairness and friendliness, and a personal understanding of the workman involved, the new force will work out to the good of all concerned. Scientific management offers an opportunity to pay better wages, but it will require strength and wisdom to apportion the economic gain fairly, and to maintain a just distribution of it."

Who can deny the truth of this argument? Lately I have been studying the problem of the human side of management and have been impressed by such state-

ments as these, by men who know: "Motion study is not a cure-all for any sort of industrial ill. A surgeon's knife can be used with killing effect in the hands of a novice. In the hands of a skilled surgeon it can be made to serve as a means of curing serious physical ailments. So with motion study. Its proper and judicious use by persons who are familiar with its application, can effect many and great economies in almost any industry." Notice the emphasis placed on the man. F. G. Coburn, Assistant Naval Constructor in the U. S. Navy, has been quoted as saying: "The system of management is but the tool of the manager. Alone it is useless, may even be dangerous — * * * labor-saving management is a system that forces the executive to manage."

How shall he manage? Shall he be fair, considerate, humane, or the reverse? Shall he delegate all dealings with the men to his subordinates, or shall he himself keep in personal touch with them? Years ago the executive was 'the old man' and personal touch was not only easy but necessary. Conditions have changed, but this does not mean that the personal touch must therefore be eliminated. The personal touch and right dealings make for efficiency, which in turn, depends largely upon the man above.

Thus, to return to our starting point, it seems clear that there are other important factors besides a system and an engineer. Among the most important of these other factors are right working, living, and recreative conditions surrounding employees, loyalty, goodwill, and the good character of the men. These conditions are brought about and these qualities are engendered in men through the influence of the man or men 'above.' How important therefore that these men themselves shall be of the right kind! Charles W. Eliot expressed the idea superbly in one of his addresses: "Without the sentiment of loyalty, happiness in labor is impossible; with it the humblest service yields solid and lasting satisfaction. * * * It is an unhappy condition of things when political liberties get disassociated from personal liberties, through change of character in the object of loyalty, or through the disillusionment of the loyal. Just industrial liberties and satisfaction in work cannot be surely won, or safely kept, without worthy loyalities. The industrial democracy needs to improve its aims and ideals as well as to get more pay, more leisure, and healthier conditions of labor; and its greatest need is a state of mind capable of unselfish loyalty." I am purposely quoting more than usual because the opinions of both the practical business man and the sociologist are worth everything.



OFFICE-BOYS GETTING ADVICE.

Every company is concerned about the securing of the right kind of employees (men of character and goodwill) and the right kind of engineers, managers, efficiency experts, etc. (men of character and ability to engender goodwill). How can such men be secured, how can they be held, and how can those already employed be transformed into the right kind of men? This is the vital question. It is both social and individual. Many organizations are working to better social conditions (the working man's environment) and to better the man

himself. Among these agencies an important one is the Young Men's Christian Association, because of its extensive service to industrial men and boys. During the past year this Association alone had in its North American membership 100,000 industrial workers, while 400,000 more were helped in extension features, educational, recreative, and character-building. Half a million men were served by the Railroad Associations, and 310,000 foreigners were definitely helped toward a knowledge of English and other things that make them desirable American citizens. All such work helps to solve the problem of man—efficiency. The work for foreigners alone affords a splendid illustration. The Association starts its service at 15 ports of embarkation in Europe, helps the men in the steerage, meets them at Ellis Island and other ports of entry, and is alert to secure employment, teach English and civics, and acquaint them with the new life at their final destination. Writing in *Factory* in February, M. C. Albright mentions a practical application of this work: "To induce in the worker the right attitude toward safety is a task that demands not only considerable tact and persistence on the part of the management, but nicety of judgement to a marked degree. * * * Various plans have been evolved to accomplish this result. The greater the proportion of low-grade and non-English-speaking help, the more elaborate must be the plans. One plan being applied with considerable success through the co-operation of the Y. M. C. A. is to combine the teaching of safety with English. Words are used which apply to operations in which the men are daily engaged." Many companies are bringing about a similar increase of labor-efficiency through well-known educational and welfare methods. Some feel keenly that it is desirable to have such work promoted by some neutral agency like the Y. M. C. A., because this removes all possibility of paternalism and misunderstanding on the part of the men.

Much also is being done by employers and others to increase the efficiency of the man above. We have noted the importance of the engineer and others in influential industrial positions being men of sympathy, tact, judgment, and ability to handle men. It is therefore especially interesting to observe the increasing care with which such men are being selected on the very basis of these human qualifications. Some of these are men of practical experience chosen from the ranks, many others come from colleges and engineering schools. Naturally, therefore, we are concerned about what the colleges are doing to equip coming industrial leaders not only with the technical but also with the human qualifications of their profession. Many colleges have, in the past, been exceedingly negligent in this respect. Business men have become disgusted with the 'product' of certain engineering schools. A general manager said to me recently, "We have in our shop graduates of about 20 different colleges and technical schools. Those fellows are a damned nuisance!" When I pressed him for an explanation he said, "They are all right on the theory, but when they begin to deal with working-men they sure do make a mess of it. They haven't got the workingman's point of view and they don't deal with him right!"

With so important a problem before us it is significant to note the growing desire of college professors to meet this need. An increasing number of engineering schools are offering courses in industrial management, and in many of these courses the human side is given a considerable place. I have before me the Pennsylvania State College syllabus announcing a complete course in industrial engineering, which includes a study of principles ("The field and methods of the science of management and the fundamental considerations as to men, materials, machines, methods, and organization which enter into the work of the efficiency engineer"), organization (including "general and departmental organization, power, light, heat, ventilation, sanitation, and transportation arrangements. Cost, time-study, labor-efficiency, wage-systems, safety and welfare methods"), management, factory planning, etc. The University of Wisconsin, Cornell University, and a number of other colleges have splendid courses along these lines, which especially bring to the fore the human side of the engineering profession. Last year Yale gave the senior engineers a special series of eight lectures, which would make them consider their human responsibilities after graduation. All these are steps in the right direction.

The Industrial Service Movement, which started at Yale seven years ago and has spread all over the country under the auspices of the Young Men's Christian Association, is helping in many ways to solve the problem. It is promoting lectures on human engineering and groups of discussion for interested students. It cooperates with the faculty in providing special class-room speakers who are specialists along these lines. It brings back to the college prominent graduates who have been notably successful in dealing with men, that the coming generation may learn something of how they do it. It has prepared special literature to convince students of the reality of the very things that I have been discussing. Most important of all, it enlists students in practical service for working-men and boys. This service may involve teaching foreigners English, instructing American workmen in technical subjects, or a hundred other things. Whatever the service is, care is taken that the college-man and working-man get together in a friendly way, which makes for mutual understanding and respect for each other's point of view. The student himself learns many things. He also comes to appreciate the other fellow and learns how to deal with the workman successfully. Scores of college-men all over the country have personally told me that such work has helped them in ways too numerous to describe. The surprising part of it is that, without interfering in any way with their studies, 3500 engineering students from 200 colleges are now finding time to do this work without any financial compensation. But who can doubt that they will be fully compensated by their future success as leaders of men? Surely industry may in the future safely count

on such men to promote goodwill, loyalty, and character, through fraternity and the personal touch. Many such a man has had his own character improved as a result of his service experiences while at college. Is it too much to expect, as the colleges train more men of this type, that the problem of management already indicated may in large measure be solved? Will not these very men help to determine aright the spirit with which 'efficiency' is applied?

J. Parke Channing, vice-president of the Miami Copper Co., read a paper on this Industrial Service Movement at the last annual meeting of the American Institute of Mining Engineers. The following quotation is a real contribution to our discussion:

"It may seem surprising that 3500 engineering students, each carrying a heavy course of study and with many other interests, can find an evening or two each week to engage in some form of definite service, without any financial compensation. But such is the case, and on the whole a careful survey of their work reveals efficiency and permanency in a high degree. If industrial men are at first suspicious, their suspicion soon wears away in the face of frankness and friendliness. If the employers have any doubts they do not last long. (If they will visit any of 200 points they will find students teaching foreigners in railroad box-cars, stores, clubs, halls, pool-rooms, restaurants, and boarding-houses as well as in the more dignified meeting-places—schools, churches, settlement-houses, and factories. They would see American working-men instructed in mines, shops, and labor-unions. They would look with interest upon recreative games, talks, first-aid, and safety promotion in all sorts of places at noon, afternoon, evening, and midnight. And we have seen 500 men crowded around the machinery of a huge plant listening to a straight noon-hour talk on clean living, character building, and vital religion). We have looked with amazement on 50 factory boys following enthusiastically a college football captain who took enough interest in them to organize a boys' club or a factory athletic league. It has all been done in the finest kind of spirit, without patronage, with modesty and with efficiency, and during the past year those 3500 student leaders reached over 60,000 working-men and boys in a very personal and directly helpful way. The secretary of this movement has talked with hundreds of employers and college professors throughout the country, and all seem enthusiastic over what has been accomplished. Fine! but what has this to do with engineering? Just this—that every one of these 3500 students would be willing to say that he has gained far more than he has given. Furthermore, a study of the situation proves that he has gained in large measure the very qualities he needs—an appreciation of working-men, adaptability, leadership, a knowledge of how to deal with men in a way to get results and to avoid harmful labor difficulties."

A TALK IN THE FACTORY.

In all this work the students are learning much more than the possibilities and limitations of welfare work. They are acquiring a personal attitude toward fellow-workmen that starts out right. If the engineer starts

out right in this way he will probably stay 'right' during the rest of his career, for goodwill is a highly-multiplying power. The number of engineering graduates who have the right attitude and method can be greatly multiplied by a wider promotion of the plan indicated. Suppose the 200,000 college-men of the country could go out into the larger world with this spirit and purpose? As it is now, recent graduates spend most of their time, thought, and skill on problems of output, and grades, tonnage, and trade. Their sensory nerves respond quickly to the suggestion of dividends and their motor nerves to making a record. In ten, perhaps five, years many of these men will be centres of power in the industries to which they have gone, and will have influence enough to determine in large measure the policies of the company they serve. Many of these men will become efficiency engineers. At their word, machinery will be torn out and new inventions installed, new methods adopted and new paces set for progress. Will these young engineers become just as influential in developing progress in the 'humanics' of industry? Why not? The plan described certainly helps to solve the problem. If the interested manufacturers of the country would, from their own experience, urge the colleges to give more attention to the human side it would help greatly to solve these problems.

These are days of great industrial and social problems in America. They are also days of good deeds. Industry is increasingly assuming its burdens. The leaders of industry are accepting greater responsibility for improving conditions. They are making possible better relationships between capital and labor. Many changes are being wisely wrought, and the watchword is 'efficiency.' Both employers and employees are becoming more anxious to attain it to a higher degree. The efficiency of those who are managed and those who manage is a more vital factor in real success than ever before. Scientific management in the best sense has a great future, and this future will be determined by the skill with which efficiency is applied.

Agricola, writing about 1550, seems to have known something of the bad side of mining, for he says: "The following are some of the wicked and sinful methods by which they say men obtain riches from mining. When a prospect of obtaining metals shows itself in a mine, either the ruler or magistrate drives out the rightful owners of the mine from possession, or a shrewd and cunning neighbor perhaps brings a lawsuit against the old possessors in order to rob them of some part of their property. Or the mine superintendent imposes on the owners such a heavy contribution on the shares, that if they cannot pay, or will not, they lose their rights of possession; while the superintendent, contrary to all that is right, seizes upon all that they have lost. Or, finally, the mine foreman may conceal the vein by plastering over with clay that part where the metal abounds, or by covering it with earth, stones, stakes, or poles, in the hope that after several years the proprietors, thinking the mine exhausted, will abandon it, and the foreman can then excavate the remainder of the ore and keep it for himself. They even state that the scum of the miners exists wholly by fraud, deceit, and lying. For to speak of nothing else, but only of those deceits which are practised in buying and selling, it is said that they either advertise the veins with false and imaginary praises, so that they can sell the shares in the mine at one-half more than they are worth, or on the contrary, they sometimes detract from the estimate of them so that they can buy shares for a small price."

Flameless combustion results when a homogeneous explosive mixture of gas and air, in the proper proportions for complete combustion (or with air in slight excess), is caused to burn without flame in contact with a granular incandescent solid, whereby a large proportion of the potential energy of the gas is immediately converted into radiant form. The advantages claimed for the new system are: (1) The combustion is greatly accelerated by the incandescent surface, and may be concentrated just where the heat is required; (2) the combustion is perfect with a minimum excess of air; (3) the attainment of very high temperature is possible without the aid of elaborate regenerative devices; and (4) by reason of the large amount of radiant energy developed, transmission of heat from the seat of combustion to the object to be heated is rapid. These advantages are so uniquely combined in the new system that the resultant heating-effect is, for many important purposes, not only pre-eminently economical but also easy of control. It is obvious that this process is adaptable to many furnace operations, as, for example, the heating of retorts, annealing-furnaces, and the like. It is not essential that the bed of refractory material shall be disposed around the vessel or chamber to be heated; it may be equally well packed into tubes, or the like, traversing the substance to be heated. This latter modification is important in relation to the melting of metals or alloys which are fusible at temperatures below about 600°C., and also in relation to steam-raising in multitubular boilers. By this process, much higher temperatures are attainable with a given gas than by the ordinary methods of flame combustion without a regenerative system. In a crucible fired by coal-gas on this system a temperature of 1880°C. is easily reached. Platinum also melts readily. Using air preheated to 500°C. with coal gas, a temperature estimated at somewhat over 2000°C. has been attained. A very resistant chromite, not melting at 1880° C., was fused in this way. Crucibles of alundum are fused without preheating the air. A 110-tube boiler capable of evaporating not less than 5500 lb. of water per hour showed great economy when fired with coke-oven gas on this system. Tanks holding 8 tons or more of molten lead heated by flameless combustion have been proved to utilize about 70% of the calorific energy of the fuel employed.

Gold output of the Rand in August was 778,763 oz., the largest yield since May 1913, when it was 794,306 ounces.

A Rule Governing Cupellation Losses

By W. J. SHARWOOD

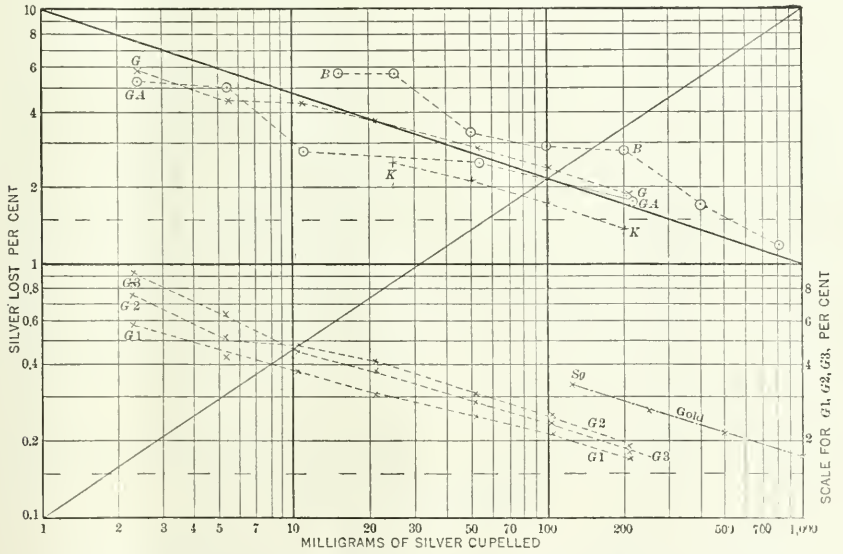
*Cupellation is well known to be one of the most effective methods of separating gold and silver from the base metals and other impurities, as well as one of the most accurate means for their estimation. In the latter application it consists in absorbing in some porous medium the fused lead oxide formed by the oxidation of the lead 'bath,' which carries with it the oxides of other base metals present.

It has long been recognized that small amounts of both silver and gold were removed and absorbed together with the base metals, as well as being to some slight extent volatilized, and in work of the highest accuracy a correction is made for the 'cupellation loss.'

Thus in the assay of bullion this is done by means of 'proofs' of like composition, which are manipulated throughout in precisely the same manner as the assay-pieces, and are assumed to lose or gain like amounts. In the case of certain very rich ores and commercial products the loss is adjusted by assaying the cupel itself and recovering the precious metal absorbed, but this doubles the labor and does not remedy the loss by volatilization. Arbitrary tables have been drawn up by various authorities with the object of enabling a correction to be applied without the use of a check. These have been of limited practical use owing to the fact that a number of factors affect the losses sustained.

For a fixed amount of precious metal the loss varies with the amount of lead used, with the nature and amount of impurities, with the porosity of the cupel, with the air supply, and above all with the temperature at which cupellation is carried on. Pure silver loses relatively much more than gold, but the loss in either is diminished by an addition of the other metal. The concentration of precious metal in the litharge increases as the concentration in the lead increases, but little work has been published connecting the two. If all conditions remain the same the actual total loss increases, but the percentage loss diminishes, with an increase in the weight of precious metal treated.

The results of an immense number of experiments have been published at various times during the past hundred years giving the actual or the percentage-losses suffered under various conditions of cupellation, but the data are widely scattered and few attempts have been made to correlate them, so that no definite law has heretofore been shown to exist governing the relation of



G = Godshall, average of three series. K = Kauffman.
GA = Godshall, average of Tables A and B. B = Beringer.
G1, G2, G3, = First, second, and third rows in muffle of Series G. Sg = Sharwood (gold).

FIG. 1.—The percentage losses, alone are given, this being the form used in most publications. Godshall's results for various muffle rows are placed for clearness in the lower portion of the diagram.

*A paper to be read at the September, 1915, meeting, at San Francisco, of the American Institute of Mining Engineers.

weight and loss, although Fulton has published curves covering certain conditions. If such a law were known it would enable a correction to be applied to a button of any weight, by a calculation applied to the loss in a proof of an entirely different weight, but cupelled at the same time under the same conditions. It is believed that such a rule is now available.

This empiric rule may be thus enunciated: When a given amount of silver (or of gold) is cupelled with a given amount of lead, under a fixed set of conditions as to temperature, etc., the apparent loss of weight sustained by the precious metal is directly proportional to the surface of the button of fine metal remaining.

Probably the calculation should be based on the original weight of precious metal taken, but in practice we have to depend on the weight remaining. Variations in the amount of lead have comparatively little influence, and temperature conditions in a given row across a muffle are nearly uniform, so that for practical purposes the ratio holds good for any one row in a cupellation run, provided the amounts of lead do not differ extremely. Most other variations have smaller effects. If the above is true the following must also be true.

The loss of weight varies as the $\frac{2}{3}$ power of the weight, or as the square of the diameter of the button.

The percentage loss varies inversely as the diameter of the button, or inversely as the cube-root of the weight.

Examination of a large number of experimental results, as well as the published data of others, proves that the last proposition is a close approximation to the truth, and therefore proves the others. The readiest proof of the rule, which avoids all calculation, is by the aid of logarithmic paper—that is, paper on which the ordinates are plotted on a scale like that of a slide-rule.[1] In place of using the ruled paper the distances may be actually laid off by means of a slide-rule scale. When plotted in this way the graph of any equation of the character $y = Cx^n$ appears as a straight line, and all straight lines for a given value of the power n are parallel. If the horizontal and vertical scales are equal (as in Fig. 1 and 2) the tangent made by the line with the x axis is the exponent n.

If therefore we plot on the x axis the weights of a series of silver buttons cupelled under precisely similar conditions, and the corresponding losses on the y axis, and the corresponding points fall approximately on a straight line, then we know that y varies as some power

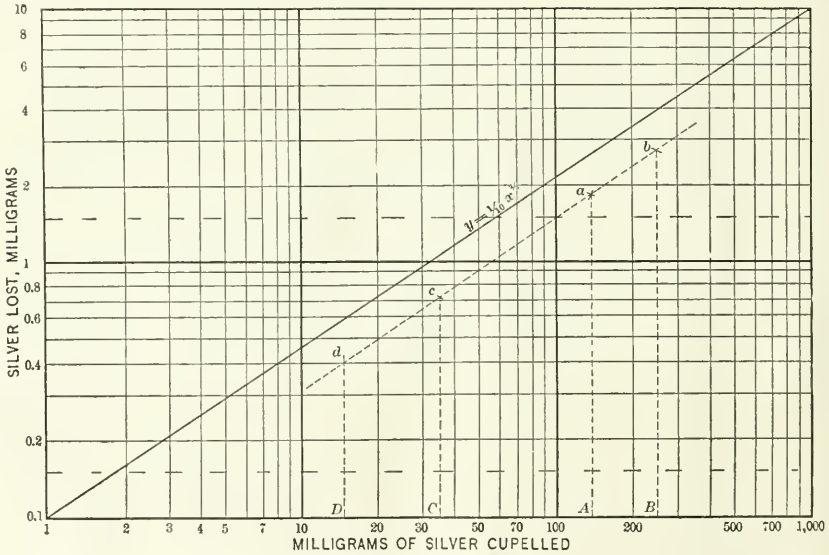


Fig. 2.

of x. Drawing a line parallel to the general run of these points from the point $y = 1$, $x = 1$ to $x = 10$ or 100, will indicate at once what the value of n actually is.

If any one will take the trouble to average and plot a series of cupel losses on buttons of various sizes carefully cupelled in the same row, he will, I think, find that they will fall nearly on[2] lines parallel to

$$y_1 \text{ (weight lost)} = x^{2/3}$$

and

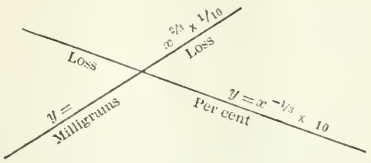
$$y_2 \text{ (percentage lost)} = x^{-1/3}$$

The distance between the parallel lines obtained in various series simply corresponds to the values of the con-

[1] Multiple logarithmic paper may be obtained at a very moderate price through the Department of Civil Engineering, University of Wisconsin.

[2] In the case of the smaller weights, say those below 10 mg., a considerable deviation from a straight line will probably be observed, unless a large number are averaged, as the relative error due to a difference of a few hundredths of a milligram then becomes serious.

stant c for different conditions of temperature, muffle-draft, etc.



A few results are shown thus plotted in the accompanying diagram.

I have found that such series as those published by Klasek, Godshall, Beringer, and Kauffman (omitting erratic ones), and a transcription of the curves plotted by Fulton, all give points falling nearly into general parallelism with the lines indicated, and my own values for silver alone and gold alone agree well except for the smaller values, where irregularity naturally occurs. This rule is the dominant factor in cupellation loss, temperature alone excepted.

As to the possible application of this rule: An approximate correction may be obtained for an ore or the like, if one proof, as near the expected weight as possible, is cupelled in each row, and its exact loss noted. The corresponding point is plotted on the diagram (a in Fig. 2, A representing the final weight), and a straightedge is placed on the diagram, or a line drawn through a, parallel to the guide line, $y = x^{2/3}$. Noting the points on the line or straightedge corresponding to the weights B, C, D, of other buttons weighed, the correction for each is read at once from the scale. In the example plotted in Fig. 2 a button of 140 mg. weight has lost 1.8 mg.; from this it appears that other buttons of 250, 35, and 15 mg. will respectively have lost about 2.85, 0.72, and 0.40 milligrams.

KAURI-GUM mining is next in importance to gold mining in New Zealand. It is found over an approximate area of 814,000 acres; over this region it occurs on both the driest fern hills and in the deepest swamps in lumps up to 100 lb. in weight. Transparent or semi-transparent specimens fetch very high prices from collectors. The great bulk of the resin is used in the manufacture of varnishes. The gum diggers use a light pointed iron rod to test the ground, from which the gum is dug out with a spade. Occasionally the diggers strike rich patches. Some Austrians took out $750 from a small ravine in 1913. In this year the product was valued at $2,600,000; the best grade gum sells for $1500 per ton. Single specimens of transparent gum the size of a man's fist have sold for $125. The Mitchelson collection recently presented to the Auckland Museum is valued at $10,000. The total production to the end of 1914 is about $80,000,000.

CINNABAR ore treated in the United States in 1914 totaled 122,988 short tons, yielding an average of 10.1 lb. of quicksilver per ton.

CHAIN-DRIVEN tube-mills at the Tonopah-Belmont mill cost $0.00184 per ton of ore treated for chain repairs.

Zinc-Dust

Summarizing his investigation of zinc-dust precipitation tests, Nathaniel Herz, of Lead, South Dakota, draws the following conclusions:

Zinc-dust, satisfactory for precipitation of precious metals from cyanide solutions, should pass the following tests: It should be fine; that is, most of it should pass through a 200-mesh screen, and the fine portion should be very much finer than the screen opening. As the surface exposed per unit weight varies inversely as the diameter of the particles, and the number of grains varies inversely as the cube of the diameter, if the average diameter of one lot of dust is one-half that of another, the finer would have twice the surface and eight times the number of particles. The dust would remain in suspension better, and, if uniformly distributed, the distance between grains would be half that of the coarser material.

The oxide should be low, but very low oxide does not necessarily indicate a good zinc. There should be a reasonable amount of lead, over 1%; as high as 4% may do no harm. Cadmium is usually present, and some cadmium may take the place of part of the lead. If oil is present, it should not be in such quantity as to prevent good mixing of the dust with the solution. Precipitation with a standard solution of silver cyanide gives a rapid method for approximating the value of a particular lot of zinc-dust. If the efficiency is well over 40% (100% being the theory for complete replacement of pure zinc by silver), the zinc is satisfactory. If under 30%, the dust will probably give poor results.

The condition of the metallic impurities may have considerable influence.—*Bulletin* 104 of the A. I. M. E.

Dredging in California

Handling Leady Copper Matte

By H. F. EASTER

*The leady copper matte produced at the El Paso Smelting Works during October, 1914, averaged Fe, 42.1; Pb, 12.1; Cu, 19.8; Zn, 4.6; S, 21.4%; Au, 0.04 oz.; Ag, 87.8 oz. The average grade of the bullion produced was: Au, 3.24; Ag, 247.6 oz. The matte produced averaged 8% of the total charge. Lead on the charge averaged 15.7%, and sulphur 2.2%. Coke used averaged 14.2%. These figures, while applying to only a single month, may be taken as fairly representative of the lead-smelting practice of the plant.

The high copper in the leady copper matte, is characteristic of the usual conditions at this plant. It had long been customary to set aside matte of about this grade until a sufficient amount had been accumulated to make worth while a concentration run. The matte produced during these campaigns usually averaged about 10% Pb and 35 to 40% Cu. It was drawn off in hand-pots, cold-dumped, broken by hand, and re-smelted through the copper blast-furnaces. All this involved considerable expense and it became evident that much of this could be saved if some means were provided for getting this molten leady copper matte direct to the converters. The round oil-fired settlers offered a convenient reservoir in which to collect the matte in fairly large quantities, and a pit 10 ft. wide and 8 ft. deep was dug immediately in front of the settlers in order to allow the approach of the 5-ton matte ladles serving the converters. About this same time the rolling-stock equipment of the plant received a much needed addition in the shape of several Treadwell slag-cars of 160 cu. ft. capacity, holding about 14 tons of slag each. These cars superseded the older one of small capacity and made it possible to handle all the slag and matte away from the furnaces over a single straight track laid in the pit in front of the furnaces, entirely doing away with the necessity for hand pots for any purpose. This, however, involved a radical change in the use of the settling-tanks, inasmuch as all the leady copper matte was run over into them and the rectangular box was used only as a collector for lead. Owing to the high proportion of copper on the charge and the large amount of dross produced, the lead-wells of the furnaces are hard to keep open, and most of the time all the lead passes out of the top hole and must be separated outside the furnace.

The direct conversion of the leady copper matte proved to be such an economy that since the introduction of this system, matte has been converted that is much lower in copper than formerly. It is now customary to figure the value of the lead contained in the leady copper matte, and therefore lost in converting, as against the cost of roasting and re-smelting in the lead furnace, taking into consideration the fact that each unit of copper present means the loss of a certain amount of lead even on a concentration run. Each day's production of leady copper matte is thus disposed of according to its assay, either direct to the converters or poured on the ground in beds, to be picked up, crushed, and roasted. As the matte has recently been rather low in lead, most of it has gone direct to the converters even though it may not run higher than 20% copper.

Under this system the whole duty of settling out the matte is put up to the large settler, and the rectangular box is used only to separate out the lead. Considerable anxiety has been felt as to whether it is safe to rely upon a single settler for the separation of the matte. In an endeavor to throw some light upon this question, the shells from the Treadwell pots have frequently been brought back from the dump and sampled with great care. The most complete of these tests covered a period of five full days early in January, 1915, all the shells produced being saved and run through the automatic sampler. The resulting composite sample showed: Au, trace; Ag, 0.64 oz.: metallic lead, 1.46; Cu, 0.30%. The average of the daily 24-hr. samples for the same period showed: Au, trace; Ag, 0.30 oz.; metallic lead, 1.24; Cu, 0.24%. These figures, which are about in line with all the others obtained under similar conditions, would indicate that it is safe to put these shells over the dump.

The comparative success attending the use of these round oil-fired settlers encouraged the installation of a somewhat similar but larger settler intended to serve two furnaces instead of one. The apparent advantages of this were the greater volume of leady copper matte that could be accumulated at one time, the certainty that one such settler would require less fuel oil than two of the earlier type, and some saving in labor.

This new settler is placed about 6 ft. forward of the line of the front crucible-plates of the two furnaces and equidistant from them. It is 10 ft. inside by 20 ft. long, extending close enough to the edge of the train pit to make it easy to tap matte and slag into the cars below without the use of excessively long spouts. The whole structure is supported upon rails running crosswise and providing air spaces beneath the bottom pan. This feature has proved to be of considerable importance inasmuch as there is a constant seepage of lead through the bottom and the open air-spaces arrest its progress downward into the foundation and facilitate its removal. The ends of the settler are slightly curved in order to give a stronger structure. The sides are braced with I-beams set upright and tied across the top with steel rods.

*Excerpt from a paper, 'Lead Smelting at El Paso,' to be presented at the September (San Francisco) meeting of the American Institute of Mining Engineers.

The sides and ends have a lining of 9 in. of magnesite brick. A matte tap is provided on each side close to the front, and there is a single lead tap in the middle at the rear end. This lead tap is used every day, but little lead is obtained, as experience with the Rhodes separators indicated the inadvisability of maintaining a bath of lead in contact with the matte, and every effort is made to keep lead from getting into the large settler in the first place. The roof of the settler is sectional, being composed of a number of rail-bound firebrick arches that can easily be lifted off if necessary. The stack is situated at the rear end immediately between the slag-inlets from the two furnaces and over the lead tap. Two oil-burners were installed, one playing downward through the roof at a point about 6 ft. back from the front, and one playing nearly horizontal through the front wall.

Between each furnace and the large settler is a removable rectangular box, 2 ft. 6 in. wide by 9 ft. 2 in. long, lined with 4½ in. of magnesite brick all around. The furnace is connected with the box and the box with the settler by short water-coil spouts. Each box is set at an angle of about 45° to the furnace, giving the tapper a clear field for his work.

As it is no longer necessary to provide for the use of hand pots under the slag and matte spouts, it has been possible to arrange the elevation of the various parts of the system to much better advantage than in the case of the round settlers. There is a difference of 20 in. between the tap hole of the furnace and the bottom of the slag-outlet from the main settler, which greatly facilitates the handling of the spouts. There is a difference of 10 in. between the bottom of the inlet and the bottom of the slag-outlet, which allows plenty of time for switching and changing slag-cars after the outlet-hole has been closed up. The normal depth of the bath in the settler is 25 in. with the slag-outlet open, and it is customary to maintain about 10 to 12 in. of matte at all times, as this seems to assist materially in keeping the settler in good condition.

Although this settler was designed for operation with two furnaces, it was decided to try it out with only one, in order to see if it might be kept open under such circumstances. At the time of writing it has been in successful operation with one furnace for exactly one month, although the amount of fuel oil necessary to keep it in good condition is somewhat greater than was the case with the former round settlers. The larger settler requires about 7 bbl. of oil per day, whereas the others averaged about 4.5 to 5 bbl. However, with two furnaces running it is probable that less oil would be required. No serious troubles have been encountered up to the present time, and careful sampling both at the furnace and on the dump indicates that the settler is standing up to its work quite well.

A NEW PYROPHORIC ALLOY, for cigarette and gas-lighters, said to be cheaper than the cerium-iron alloys, and not subject to disintegration, is: Mn, 80%; Sb, 10%; and Cr, 10%. The alloy is air-proof, and is said to produce a long streak of flame, instead of a shower of sparks.

Leaching Copper Ores

The new 250-ton leaching-plant at the Nevada-Douglas mine, Lyon county, Nevada, after much delay, was started in August. Sulphide and oxidized ores will be treated separately and by entirely different methods. The copper, iron, and sulphur are made use of as marketable products. In the treatment of 50 tons of sulphide ore, enough sulphuric acid is obtained at a very low cost to treat 200 tons of oxidized ore. A brief outline of the process is as follows:

The sulphide ores are submitted to acid treatment under pressure in a closed receptacle, in which operation the sulphides of copper and iron are converted into the sulphates of the metals and taken into solution. This solution is then decanted and passed through electrolytic cells, or over scrap iron where the copper is removed. The remaining iron-sulphate solution is then carried to an evaporating-tower, where the water is evaporated and the ferrous and ferric crystals are allowed to crystallize out. These iron sulphate crystals are then put into a dryer and submitted to a temperature sufficiently high to drive off all the water of crystallization. The dried sulphates are then roasted in the Wedge muffle-furnaces, sufficient heat being applied to decompose the sulphates. The greater portion of the gases coming off in the form of sulphur tri-oxide is collected in the absorption-towers and made into sulphuric acid. This is used in leaching the oxidized ores. The remaining residue of ferric oxide is then drawn off and prepared for market.

Leaching of the oxidized ore is carried on in Pachuca tanks, where the ore is agitated with air and leached with the sulphuric acid obtained from the preceding sulphate roast. The solution is then decanted, and passed through electrolytic cells, where the copper is taken out, after which the water is evaporated. The sulphate crystals are dried and roasted in the muffle-furnace as described before.

It will be seen that there is no sulphuric acid lost except that which is consumed by the limestone, and that portion of the sulphur which goes to form sulphur di-oxide in the furnaces.

The total cost for mining and treating sulphide ores is $5.18 per ton. As the average of the ore to be treated is a little above 3% copper, the ore will have a gross value of $12 per ton in copper and will sell at a net profit of $6.82, exclusive of the value of the iron and sulphuric acid. The total cost of producing a ton of iron and sulphuric acid by this method should not exceed $2. With sulphuric acid at this price, oxidized ore as low as 1% metal can be treated at a profit.

BELTS properly tightened with belt-clamps fitted with spring-balances properly to register the tension, according to standards established by careful experimenting, will average twice the pulling power and only a fraction of the interruptions of belts tightened according to the usual methods. As a rule belts should be much heavier than the general practice.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Efficiency = equipment × the human factor.

Solar salt is a name given to salt produced by solar evaporation.

Strontium hydroxide is used in the beet-sugar industry. Germany consumes 100,000 tons per year.

Silver in ore at Shafter, Presidio county, Texas, occurs mostly as a chloride. The output since 1882 is over $7,000,000.

A Klondike miner is said to have taken $600,000 out of a claim 86 by 300 ft., but he died in poverty. One of the quickest fortunes was made by two men who cleaned up $65,000 in 27 hours.

A peculiarity of the Porcupine goldfield is the way in which the metal is 'shot' through the schist on either side of the veins. This is so to such an extent that in some of the mines a vein of two inches of quartz is mined to a width of five or six feet.

The system of passing the fine material from rock-crushers direct to tube or other mills, instead of having it crushed by stamps, is growing in favor. Good and economical results are made at the McIntyre mill, Porcupine, Ontario, by this arrangement.

Artificial crystals of gypsum have been made at the University of Turin, Italy. Limestone kept for two years in a solution of $FeSO_4$ was gradually converted into gypsum. Because of the slowness of the process the gypsum crystals were obtained in a large variety of forms.

Poona is a mountain sickness that attacks people at an altitude of 11,000 ft. in the Andes of Argentina. These mountains are quite different to the Sierra Nevadas in North America. A height of 10,000 ft. is trying in the Andes, but in Mexico this elevation is unnoticeable.

Retention of men in a company's employ is desirable, and some inducement should be made to keep them continuously. Twenty manufacturing firms in the East employ an average of 2200 men, but to keep 44,000 regularly employed it was necessary to hire 69,000 men, resulting in large monetary losses.

Bentonite is a kind of clay which has a variety of uses. It is employed to give body and weight to paper, in the preparation of a dressing for inflamed hoofs of horses, as a constituent of antiphlogistine (a proprietary remedial dressing), and as an adulterant of candies and drugs. It has large powers of absorption, taking up about seven times its own volume of water. It absorbs twice as much glycerine as can be absorbed by diatomaceous earth, and for this reason has been suggested as a substitute for that material in the manufacture of dynamite.

Mineral waste is estimated at $1,000,000 a day by the Bureau of Mines. Waste of natural gas is about $250,000; petroleum waste is $150,000 daily; waste of human life is about 2600 per annum, at a minimum valuation of $5000 per life this waste amounts to $13,000,000 annually.

Staurolite is an iron-aluminum silicate found only in Virginia and North Carolina. The reddish-brown and brownish-black crystals occur in well defined single and double crosses. There is some commercial demand for the crosses as curios, which are worn as watch charms or on chains in the manner of a locket or lavaliere.

Agricola's advice to the buyer of mining shares, though written about 1550, is still sensible. He said, "Moreover, a prudent owner, before he buys shares, ought to go to the mine and carefully examine the nature of the vein, for it is very important that he should be on his guard lest fraudulent sellers of shares should deceive him."

Death-payments under the Workmen's Compensation Acts are a maximum of $6000 in Alaska and a minimum of $2500 in Colorado, while California and Nevada pay $5000. The foregoing refers to the mining States. In the agricultural and manufacturing States the average payment is $3000. Colorado stands out as the State that is least generous to the miner.

Well No. 7 of the Mexican Petroleum Co., south of Tampico, was brought in on September 11, 1910. Since then, up to May 1915, it has flowed at the rate of 20,000 bbl. per day, the estimated output being 39,000,000 bbl. This is by far the largest quantity of oil ever economically recovered from one well in any part of the world. The oil averages 19.3°B., or 0.9376 specific gravity.

Wire ropes coming in contact with water, especially where there is an acid or alkaline tendency, should be carefully and regularly lubricated. The lubricant used should not only penetrate to the hemp centre and thoroughly saturate it, but should also properly coat the inside wires, and have sufficient consistency to cling to the rope and not drop off and leave it practically dry after a few days.

Oil and gas have probably been derived from organic matter contained in shale or limestone, which has been distilled under conditions of heat and pressure produced by earth movement, according to C. H. Wegemann, of the U. S. Geological Survey. The oil may have been impelled through the rock pores to its place of accumulation by water under the forces of capillarity and gravity, or it may have migrated through the rocks in the form of gas which afterward condensed into oil.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

GOLDFIELD, NEVADA

Kewanas, Jumbo Extension, Sandstorm-Kendall, Merger, Atlanta, Great Bend, Silver Pick, and Diamondfield Black Butte.

Development in the Kewanas mine, where a promising orebody was opened lately in the shale-contact area, has been slightly retarded by the necessary timbering and installing additional equipment at the winze, through which ore and waste are extracted and trammed to the shaft of the Laguna mine of the Goldfield Consolidated. The drift, at a depth of 840 ft., has followed the ore for a distance of nearly 100 ft., showing an average width of 3 ft. of shipping ore, assaying from $40 to $60 per ton, with a total width in places of 5 to 6 ft. The discovery is generally considered one of importance as the orebody or ore-channel, in the contact-zone, is similar in many respects to that in the Jumbo Extension, at the south, and apparently is the extension, on its rather flat dip, of the rich deposit found in the Laguna mine to a depth of 600 ft. and farther west, in the Red Top mine, nearly to the surface. An ore-pocket is being cut at the top of the winze, on the 700-ft. level of the Laguna, and a skip is being installed. With this work and some necessary timbering completed, more rapid progress will be made; the main drift will be extended along the ore-channel, raises will be driven, following the dip of the shale, and another cross-cut, 40 ft. north of the winze, should reach the vein within the present week. With the present equipment, according to the manager, A. I. D'Arcy, a production of 100 tons of ore per day can be made without difficulty.

The Jumbo Extension mine continues to show many faces of high-grade ore, both in the shale-contact zone and in workings within the shale. The superintendent, J. K. Turner, regards the discovery of ore in the shale as important, below the foot-wall of the great fissure that penetrates the shale, where there is evidence of a considerable degree of fracturing and of accompanying enrichment. Development in the contact-zone, above the rich 524 drift, and apparently near the top of the hill or ridge of shale in this territory, has yielded excellent results, the northeast drift from the top of the new raise showing 5 to 6 ft. of ore that has assayed from $120 to $220 per ton. In the southeastern part of the Velvet claim the new drifts from raise 526-A, above the 1017-ft. level, continue to reveal ore of excellent grade, while drifts on several levels continue to develop ore far to the east and west of the main workings. A cross-cut will be driven on the 1017-ft. level, from a point near the southwestern corner of the Polverde claim to connect with the Velvet shaft, and by the time the latter is completed this cross-cut will afford connection with the workings throughout the mine. Production is maintained at the rate of 80 tons per day, the ore assaying from $40 to $60 per ton, and it is said there will be no difficulty in maintaining an output that will net the company from $55,000 to $60,000 per month. This rate of production will probably be doubled early next year, with the completion of the Velvet shaft.

On the Sandstorm-Kendall, the station at 200-ft. in the winze below the 500-ft. level, has been completed, and a cross-cut has been started to reach and explore the hanging-wall side of the lode, which is fully 70 ft. wide. The winze entered the foot-wall country a short distance, but the cross-cut is already exposing quartz. Prospects are considered to be encouraging, as small deposits of rich ore have been found at a number of points in the big vein on upper levels. It is proposed eventually to sink to the shale-contact.

In the Merger Mines property the east drift at a depth of 1175 ft. is being advanced, having re-entered the contact-zone after progressing for a considerable distance in shale. This drift, extended from the Grizzly Bear shaft of the Goldfield Consolidated, was advanced at the rate of 10 ft. per day for some time, but has lately required timbering.

Development work in the Atlanta mine continues to expose large quantities of medium and low-grade ore, carrying more or less copper. It is pretty well settled that this ore will be treated here at a good profit in the near future. Cross-cuts on the 1750-ft. level have exposed ore over a wide area, and drifts on the 1660 and 1620-ft. levels are also in good ore. The south drift at the latter depth has lately exposed 3 ft. of $40 ore, nearly all gold, and two raises above this level show seams of good ore, some of them giving assays up to $75 gold per ton. The Atlanta is regarded as a low-grade mine, but already has a large tonnage in sight.

On the Great Bend most of the preparatory work has been completed and old workings on the 400-ft. level have been cleared of debris. A large pump has been ordered, and will be installed at 400-ft. Development will then make better progress. In a raise from the 400-ft. level, lessees exposed some rich ore over six years ago, and other lessees have made money working the upper levels.

The Silver Pick Consolidated is obtaining good assays in the west or Phelan vein, now being explored by drifts on the 500-ft. level. A cross-cut is being driven to the east or main lode on the 600-ft. level.

Lessees on the Diamondfield Black Butte property have exposed some ore of shipping grade.

FAIRBANKS, ALASKA

Rhoads-Hall Mine Closed on Account of High Cost of Supplies.—Newsboy Being Examined.—Tolovana, Reliance, American Eagle, Mizpah, and Fairbanks Creek Properties.—Stamps *v.* Huntington Mills.—New Drag-Line Excavator.—Tolovana.—Antimony.

The largest quartz mine in the district, in point of production, the Rhoads-Hall on Bedrock creek, is to be closed temporarily. It has made a large production of gold, probably a total of nearly $1,000,000 in the last five years, which, apart from a few hundred tons crushed during development, has all been produced by the 5-stamp mill. Practically all of the upper levels are depleted, and work will be resumed only when cheaper power is available. By the upper levels is meant the ground above the main adit, and above a sub-level 70 ft. below. Considering the quantity treated, the mine has made a remarkable record, but fuel costs are becoming so heavy, coupled with increased water and poorer ore in the lower levels, that it was deemed best by the management to stop work until either a central power-plant is erected in the district, or the coalfields can be opened by the Government. With the assurance of a Government-owned railroad, and development of the coal areas, we expect to see this property re-opened within a few years.

The Newsboy mine was unwatered at the end of August to

permit of an examination by men contemplating further development. This property has been idle for over a year, the orebodies developed by the limited amount of work having been exhausted. Competent engineers consider the mine to be worth further exploration. Probably $150,000 has been won from the upper levels, the orebody being 17 ft. wide at 15-ft. depth.

Another promising property which is likely to be resuscitated in the near future is the Tolovana quartz mine on Willow creek. As the present management has not seen fit to even lease the property, it will probably hasten its development to have the mortgage foreclosed and the property change hands.

The Reliance mine has recently been sold to satisfy a labor lien. Whatever disposition of the property is made, it is likely to be re-opened in a short time. $80,000 was produced in a few months.

By far the most promising development of quartz mining in the district is seen on upper Fairbanks creek. At the extreme head of the creek, Foss and Farvean have a lease on the American Eagle claim, and since installing an Ingersoll stoping-machine they have been steadily increasing the output. The ore is crushed in the Heilig customs mill, 100 tons being reduced recently. The ore assays between $16 and $20 per ton. Another 100-ton shipment will soon be ready. At present, the lessees are working the 'stoper' with steam, which, while uncomfortable to work with in the stopes, is so far ahead of hand drilling that they are quite satisfied with its performance.

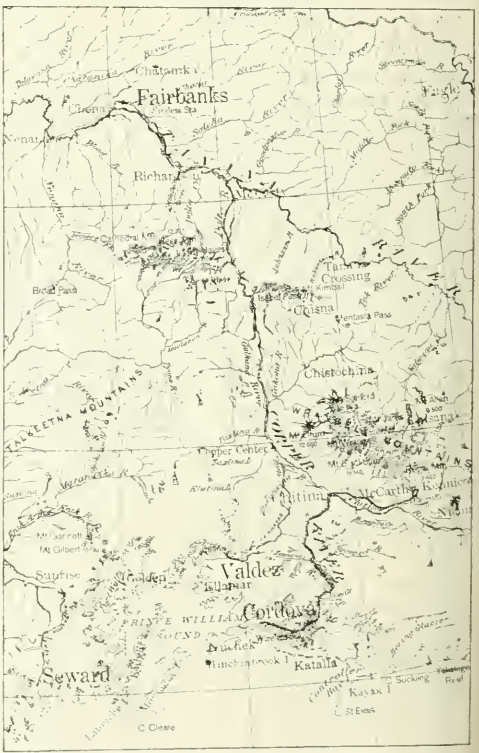
Lately, 38 tons of ore has been shipped to the Heilig mill by August Hess from the Mispah mine nearby. The ore returned $46 per ton. Development is being hastened. On another claim owned by the same people, (Hess, Geis, and Thompson) Ott and McGowan are working a lease and expect to have ore extracted in a few weeks.

T. Gilmore has recently acquired a large interest in Fairbanks Creek properties by buying into the McNeil-Huddleston property, and a half share in the Stevens-Connors claims. A 5-stamp Allis-Chalmers mill is being erected on the latter mine, provision being made for another five stamps later. The plant will be finished early in September. The first run will be on 100 tons from the McNeil-Huddleston-Gilmore property. The main supply of ore for the mill will be drawn from the Gilmore-Stevens claims where a 7-ft. vein, averaging from $12 to $15 per ton, has been developed. At least 10 months' ore is blocked out. There was 175 tons crushed at the Heilig plant to test the shoot. As both the new and the Heilig mills are on the same claim, and most of the producing properties are within a mile of both, a township is growing in the vicinity. The left limit of Fairbanks creek, at this point, has always been thawed ground, and a high channel making water available in large quantities makes of it an ideal mill-site. Heaton & Miller, lessees on a small cross lead on the Stevens-Gilmore ground, have just treated 100 tons at the Heilig mill. The returns were far from satisfactory, and the lease will probably be abandoned.

Goyette and Mareno, a claim-length down the creek, say they have cut the extension of the large Stevens-Gilmore vein. No test of the ore has been made so far.

On the group of eight claims owned by Cook Bros., Lundblad, Hopkins, and Drury, still farther down the hill, Drury and Lamprecht have opened an ore-shoot with a 30-ft. prospect shaft and 75 ft. of drifts in the last two months. Twenty-five tons of ore has been milled by the lessees, the clean-up netting $663 after paying bank charges. If the rest of the ore blocked out yields as well, more extensive development will be undertaken.

It will be interesting to compare the work of the two small quartz mills; Gilmore's five stamps and the Heilig Huntington mill. The capacity of the 3½-ft. Huntington is equal to the five stamps on the same ore crushing through the same screen, 15 tons per day can be reduced by the former through 40-mesh. In fact, several runs have shown that a ton an hour was being crushed. The fuel costs are also undoubtedly lower for the Huntington, judging from the records of other five-stamp mills in the district. The only trouble with the Huntington mill was caused by the necessity of using roll-shells cast at a local foundry, while waiting for some made by the Standard Steel Co. The local product showed the structure of Swiss cheese when broken, and lasted about a week. There can be no doubt that with good shells, the muller-shaft bearings in the hanger, as in the improved mill, instead of in the roller-head, and then substituting a Hyatt roller-bearing in the



PART OF NEW MAP OF ALASKA ISSUED BY THE U. S. GEOLOGICAL SURVEY.

hanger instead of the bushing, the Huntington mill will compare with any roller mill on the market for the work here.

The drag-line scraper for open-cut work, built by Hanot Bros. in a local shop last winter, is proving a great success. A great saving in time and power per load is shown over the old style of scraping direct into the sluice-line, or even to a car that serves the sluice-line. The Hanot scraper is rigidly attached by its bale to a carrier which rides a cable to the dump-box. Slacking the carrier-cable and regulating the length of line to the hoist, the engineer can drop the scraper in any part of the cut. A load is picked up quickly, as the weight of the carrier facilitates digging. Tightening the carrier-cable picks up the load which is quickly pulled to the dump-box, there to be emptied by special trip-line. It is a very flexible system, and will probably be widely adopted by open-cut operators in this district.

It is certain that the new Tolovana district will at least be a small one. While no high-grade 'pay' has been found as yet, there is a good area that can be profitably worked. The

ground so far sluiced has produced about 700 oz., and showed the ground to average between $1.50 and $1.25 per sq. ft. of bedrock. Operations have been hindered by lack of supplies and high prices, but the new road now being constructed will better these conditions. The road will connect with Olnes on the Tanana Valley railroad, and is being made by the Road Commission, aided by $5000 in funds subscribed by Fairbanks citizens. So far, Livengood creek is the only area where pay has been found, and most of production has been made by Patterson and Finley. Late arrivals from the district, however, state that pay has been found in one hole on Mike Hess creek, which is separated by a low divide from Livengood creek and flows to the Yukon side.

The demand for antimony has had the effect of starting real production in this district. Two hundred tons went down the river on the last boat, and much more will be shipped by way of St. Michael before the freeze-up. The shipment consisted of 25 tons mined by Jack Leach of Ester creek, and the remainder was produced by E. L. Scrafford from the head of Wildcat creek. The latter deposit has at least several thousand tons developed, which, considering that it has been opened in the last two months, is good. As antimony has been considered practically worthless here before on account of high freight rates and low prices outside, no properties have been developed before the present demand made it profitable. Many promising prospects are known in the vicinity of Fairbanks, and a rumor is afloat that one of the largest of these will soon be exploited on a large scale.

KALGOORLIE, WESTERN AUSTRALIA

Discovery at Mt. Holland.—Horse-Shoe Developments.—Edna May Flooded.—State Assistance in the Shape of Treatment Plants.—Calc-Schist.—Gravel Deposits.

A discovery was made in July at Mt. Holland, half way between Southern Cross and Hopetoun on the south coast, and 90 miles south of the former place. Four parallel quartz lodes have been found, but no work to prove anything has yet been done. The Edna May Golden Point and Junction companies, at Westonia, have closed down, and G. Stokes, the manager, with a dozen men, has left for Mt. Holland to prospect four leases comprising 96 acres, on which an option has been taken. Mr. Stokes states that the vein is 46 in. wide, and worth $8 to $40 per ton. Three other areas have been acquired by Melbourne people on which men will be working shortly. Luckily rain continues, 3 in. falling during July. As a rule, the Mt. Holland district is too dry for prospecting, and the most will be made of this abnormal season.

The report of Torrington Blatchford, government geologist, on Mt. Holland, is very disappointing after the wonderful reports published by prospectors and others. Mr. Blatchford stated that carefully broken samples of the lode exposed in trenches, panned by himself, were low and scarcely payable. Taken as a whole, the reports of the field have been much exaggerated, and against such the public should be warned. R. G. Stokes, who took an option on Colreavy's reward leases, confirmed prospectors' reports, and gave results of $7 to $40, and an average of $15 per ton.

The latest estimate of the Golden Horse-Shoe's ore reserves is 814,280 short tons worth $7.76 per ton, compared with 800,000 tons of $7.28 ore a year ago. Development on No. 4 lode has been very satisfactory on the four bottom levels. It is likely that the revenue and profit will continue to improve. Work on No. 2 and 3 lodes at the south end of the mine has not been so satisfactory, but J. W. Sutherland, the manager, is satisfied that further exploration will materially improve the position.

Work at the Edna May has been delayed by water at the 300-ft. level, but the lode was cut early in August. The manager, M. T. Williams, reports that the pumps are lifting 720,000 gal. per day.

Since its inception in 1897, the State Government mill system, now consisting of 34 plants in all parts of the State, has treated 1,017,560 tons of ore for $18,468,800 by amalgamation, $2,536,600 from sand, $529,900 from slime, and $16,600 from slag, etc, a total of $21,551,900. According to official figures, the operating loss was $270,000, but the recovery of this large amount of gold has been a great benefit to many. Tin ore has also been treated by the mills for prospectors to the extent of 68,260 tons, returning $423,100, and without this aid the tin would have remained, like most of the gold, in the ground.

The manager of the Kalgurli mine, R. S. Black, has announced that, including July, the grade of ore treated and profit earned will be reduced. This step has been expected, as no sinking has been done since July 1910, when the calc-schist area was entered. In the Lake View mine a good shoot of ore has been opened in calc-schist at 2100 ft. However, there is no doubt that the calc-schist has seriously impoverished the lodes, and a gradual decline is inevitable, so far as the Golden Mile is concerned.

A recent flotation in Melbourne, Victoria, is the Nullagine Mining Co., with a capital of $250,000 in 100,000 shares of $2.50 each. Well known Australian men are interested. The property in the northwest is estimated to contain 600,000 tons of gravel, with a recoverable value of $425,000. The cost of working is stated as $215,000. From 1,000,000 to 2,000,000 tons of lower, but unstated, grade material is said to exist. Previous attempts to work the deposit proved unsuccessful.

In June, gold mines in this State yielded a total of $2,151,000. Dividends amounted to $648,360. Some of the yields were as follows:

Name	Tonnage	Value	Profit	Dividend
Great Boulder	18,640	$242,950	$129,600	$328,100
Kalgurli	10,390	104,300	58,700	.....
Golden Horse-Shoe	23,977	196,670	45,200	225,000
Ivanhoe	19,852	159,700	45,100	.....
Edna May	2,766	61,700	40,480	32,140
Sons of Gwalia	13,542	101,600	26,980	40,620
Sand Queen	2,100	42,000	25,500	22,500
Fenian	3,216	46,300	22,300	.....
Lake View and Star	18,152	106,600	17,700	.....
Perseverance	20,827	117,600	17,300	.....
South Kalgurli	9,630	61,900	11,100	.....
Bullfinch	6,385	40,000	11,000	.....
Ingliston Consols	2,115	20,300	10,100	.....
Victorious	3,764	26,600	7,500	.....
Mararoa	2,690	24,200	6,500	.....
Menzies Consols	2,351	25,500	4,500	.....
Yuanmi	4,478	39,600	3,600	.....
Associated	10,455	61,000	3,500	.....
Oroya Links	12,000	64,800	3,300	.....
Associated Northern	381	19,500	2,900	.....
Commodore	740	7,700	2,100	.....
Great Fingall	5,030	39,000	1,400	.....
Golden Ridge	1,510	12,200	1,000	.....
			Loss	
Edna May Central	1,830	7,100	1,600	.....
Ida H.	1,357	23,400	4,500	.....

The report of the Great Boulder Perseverance company, Kalgoorlie, for the quarter ended June 30 contains the following:

Development, feet	876
Broken ore in stopes, tons ($5.40 per ton)	261,366
Ore treated, tons	61,212
Value of gold and silver (15,662 oz. and 3492 oz.)	$322,000
Operating costs, per ton	$ 4.40
Profit	$ 31,000

Work in the southwest part of the mine at 900 ft. resulted in a lode being opened, the present length being 60 ft. The company has decided to do little more development, but treat only the ore from the present stopes.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Fairbanks

Representative business men of Fairbanks have visited the Tolovana district, and returned optimistic. Mike Hess and Livengood creeks are yielding good returns.

Ketchikan

(Special Correspondence.)—The mining possibilities of this district are being more fully realized, owing partly to the resuscitation of several properties.——The Granby Consolidated is shipping nearly 12,000 tons per month from the Mamie mine at Hadley, and over 3000 tons from the It near Kasaan. ——Preparations are being made to ship high-grade ore from the Goodroe mine at Karta bay. A large quantity of concentrating ore has been developed in this mine. Some platinum has been reported besides the gold and copper contents.—— The Rush and Brown continues to ship steadily, producing about 1000 tons per month.——Axel Carlson has leased the Cymru mine at North arm, and is almost ready to make a small shipment.——Ickis and Polson have reached a vertical depth of 135 ft. in their lower adit at McLeans arm. The upper adit is in 40 ft., with 30 ft. of backs, showing 24 in. of high-grade gold-copper ore.——Four gold mines are operating on a small scale.

Ketchikan, September 10.

ARIZONA

Greenlee County

Unless the mining companies at Clifton, Morenci, and Metcalf can settle the wage dispute, they will close their properties for six months or more. Although many Americans were employed, the Mexicans are mostly affected by the strike. Wages are based on the price of copper.

The Shannon Copper Co. reports as follows for the second quarter of 1915: ore treated, 72,999 tons; copper produced, 2,867,000 lb.; gold, 320 oz.; silver, 16,100 oz.; profit from mine, $160,259; profits from railway, $4389; excess of assets over liabilities, $507,674. Costs were reduced considerably. A 150-ton leaching plant is to be erected to treat slime and other material. This will be increased to 500 or 600 tons if successful.

Mohave County

At 375 ft. in the Gold Reed mine at Oatman some good ore was opened last week.——The Big Jim shaft is down 160 ft., and prospects are considered to be bright. Machine-drills are used.——The Arizona-White Chief Mining Co. has been incorporated to work at the south end of the Oatman district.—— The property of the Arizona-Tom Reed company is to be developed in charge of G. F. Moser.——The Jerome-Oatman company is sinking. Machinery is to be ordered.——The 200-ton flotation plant at the Golconda zinc mine, at Union Basin, is expected to be ready early in January.

In the *Mining and Oil Bulletin* of the Los Angeles Chamber of Mines and Oil for September is published a résumé of the report of W. H. Weed on the United Western mine at Oatman. The geology of the district is briefly given, and some general remarks on the United Western and United Eastern properties.

Yavapai County

The Bonnie mine, which has been closed for a long time, is to be drained and re-opened. A fair amount of work has been done at the property, which contains gold, silver, copper, and lead ores. R. M. Garrett of Prescott is largely interested.

CALIFORNIA

Amador County

Following is the preliminary report of output and costs of the Plymouth Consolidated for August:

Ore milled, tons	10,800
Total value	$53,236
Working expenditure	29,198
Development charges	1,906
Surplus	$22,132

At 3200 ft. in the Central Eureka some good ore has been cut. Thirty stamps are dropping in the mill.——The old Rose or Poundstone mine, near Sutter Creek, is being unwatered.

Eldorado County

The Nipissing Mining Co. of Canada has taken a bond on the Day mine, three miles northwest of Placerville near the Coloma stage road. The price for the 55 acres is $100,000. The property can be developed by adits. The ore is somewhat refractory.

The Greenwater and Death Valley Copper Co. has closed its property, two miles south of Shingle Springs, for good. Work was only started recently, but results were unprofitable.

From 97 lb. of black sand saved in sluice-boxes during gravel washing on Hangtown creek, near Placerville, two miners received payment at the rate of $2390 gold and 23 oz. silver per ton from the Selby smelter.

Nevada County

The claims of Carter Bros., at Missouri bar, south Yuba river, have been acquired for the Hearst interests by Stuart J. Rawlings, their engineer.

Rich gold ore, valued at over $40,000 has been found at Sacramento. It is supposed to have come from the Empire mine at Grass Valley. Arrests have been made.

The Brunswick company at Grass Valley is employing 150 men. A dividend of 6c. per share, $24,000, is to be paid.

Shasta County

It is said that the Balaklala company will ship ore to the Tacoma smelter, Washington, in addition to the 125 tons daily to the Mammoth smelter at Kennett.

A 5-ft. vein has been cut in the Greenhorn mine which is producing rich ore. Shipments are to be increased to 20 tons per day.

Sierra County

The Sixteen-to-One mine is producing some good ore again. Twenty men are employed; also 10 each at the Oriental and Golden Fraction mines. These are near Alleghany.——Near Forest, a shaft is being sunk at Rock creek to cut the north extension of the Bald Mountain extension gravel channel. It is down 76 ft., having passed through strata of hard and soft lava.

COLORADO

Lake County (Leadville)

At the Penrose shaft the pumps are nearly down to 600 ft. depth. Everything is working well.——Extensive development is under way at the Susquehanna mine at the head of Lackawanna gulch. The adit is in high-grade silver ore.——Rich gold ore continues to be extracted from the St. Louis adit.—— Lessees at the Reveille have opened a shoot of rich gold ore. ——A large area of placer ground above Twin Lakes is being prospected by local people.

Park County

Just over the line from Lake county the Hill Top mine is employing over 50 men. A good deal of lead-zinc ore is being extracted. Denver people own the property, which is in charge of S. Doran.

IDAHO

Shoshone County (Coeur d'Alene)

The Stewart Mining Co. will distribute 10c. per share, or $123,836, on September 30. This makes $681,099 for the year, and $1,981,507 to date.——The Frisco mill of the Federal company is closed for an overhaul.——The Mark Cooney claims near Burke have been acquired for Eastern people by W. M. Neary of Spokane for $150,000. Three 200-ft. adits have been driven, and good lead-silver ore opened. Machinery is to be ordered for new equipment.

Under the auspices of the Coeur d'Alene mine operators, American Mine Safety Association, and U. S. Bureau of Mines, a great first-aid contest was held at Wallace last week. The following teams, consisting of six men each, were entered: Morning mine, one team; Interstate-Callahan, one team; Tamarack & Custer, one team; Success, one team; Bunker Hill & Sullivan, two teams; Stewart, one team; and Hecla, two teams. The contest consisted of a one-man, two-men, three-men, and a full-team event. Each consisted of the solution of one problem selected from four, the contestants not knowing which problem would be selected. In the full-team event 15 minutes was allowed, in all other events 10 minutes. The work of the teams was of great interest, and all showed a surprising degree of proficiency, according to the *Wallace Miner*. Following are the results: Hecla, underground, 99¾; Hecla, outside, 98⅞; Bunker Hill & Sullivan, outside, 98½; Bunker Hill & Sullivan, underground, 97¼; Tamarack & Custer, 97¼; Morning, 96⅜; Stewart, 94¼; Interstate-Callahan, 93; and Success, 91⅛. A banquet, at which 120 attended, including the contestants and representatives from the companies, was held in the evening. It was decided to hold a contest in 1916.

MICHIGAN

The Copper Country

A considerable amount of diamond-drilling is being done throughout the district, from Keweenaw through Houghton and into Ontonagon county, the White Pine, White Pine Extension, Onondaga, and Nonesuch being in the latter area.

At the Mass mill the second stamp will be followed by rolls. This will increase the tonnage by 200 per day. The present quantity is between 32,000 and 35,000 tons per month. A third compound stamp may be required soon; this will cost $25,000.

MISSOURI

Jasper County

Between midnight on September 14 and 8 a.m. on the next day 7.1 in. of rain fell at Joplin, the heaviest fall ever recorded. Damage is estimated at $500,000. Many mines were flooded, the Napoleon mine having 80 ft. of water. At Carthage 9 in. was registered.

Last week Jasper county voted a bond issue of $100,000 to pay for the erection of a tuberculosis sanatorium.

MONTANA

Fergus County

During August the Barnes-King company's North Mocassin mill treated only 1464 tons of $9.90 ore on account of litigation. The Piegan Gloster mill treated 1800 tons yielding $16,000.

Lewis and Clark County

(Special Correspondence.)—The Wickes Corbin Copper Mining Co. in the Wickes-Corbin district has leased and bonded part of its property to Oskar Karri and associates of Butte for $250,000, on two years' time. This property is considered one of the most promising in the district, having been under development by the owners for the past seven years. The shafts now being sunk are all in a good grade of copper, silver, and lead ore, shipments of which will be started within a short time.

The Cullen-Miller company in the Scratch Gravel district has cut its vein on the 200-ft. level. The shoot is two feet wide and contains high metal-content. This vein is an extension of the one being worked in the Franklin mine, which still continues shipments.

Huffaker and Hill are shipping ore from the Eastern Bell, which was leased and bonded by them from the Helena Mining Bureau. One car averaging $25 per ton has been shipped, and another one is being loaded. The vein, which started flat, has turned down at an angle of 45°, and is four feet wide with higher value.

Helena, September 8.

Mineral County

The mill at the Iron Mountain mine, near Superior, east Coeur d'Alene, is being enlarged to treat 250 tons per day. A large deposit of zinc and lead ore has been developed. One hundred and twenty-five men are employed.

The Inter-Mountain company's new 125-ton mill at the Amador mine is nearly ready. There are 50 men employed.

Silverbow County

Wages paid by all industries at Butte in August totaled $2,500,000. The following mining companies contributed: Anaconda, $1,180,000; Butte and Superior, $170,000; North Butte, $93,000; East Butte, $90,000; and Clark interests, $60,000.

NEVADA

Nye County

Five companies and several lessees at Tonopah last week produced 9861 tons of ore worth $203,458.

August outputs are as follows: Belmont, 15,104 tons yielding 250,636 oz. bullion and $68,824 profit; Jim Butler, profit of $31,553 from 4800 tons; and Tonopah Mining, 12,280 tons for 216,300 oz. bullion and profit of $57,220.

North from 601 winze in the West End the faulted vein has been cut again.——Lessees at the Montana are working steadily.

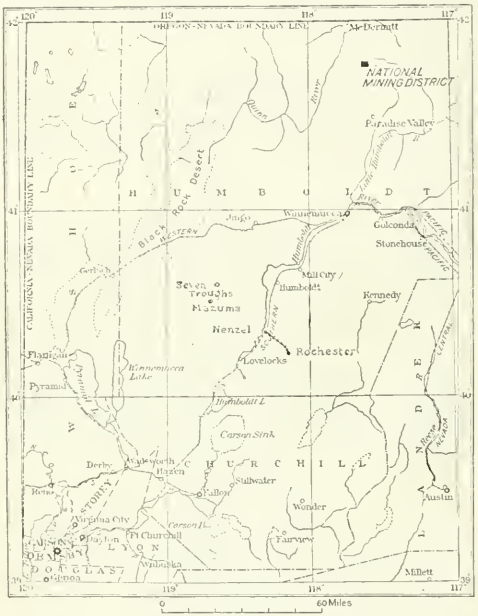
White Pine County

The Nevada Consolidated company's *Safety-First* for August states that the rate of accident frequency shows little, if any, improvement. The mishaps were as follows: Copper Flat steam-shovel mining, 7; Ruth mine, 6; mill, 2; and smelter, 1. The Congress safety shoe is advised to be worn in the smelter.

Humboldt County

Little is heard of National, a centre which was conspicuous some time ago on account of the rich ore extracted from the National vein (between $3,000,000 and $4,000,000 to the end of 1912), and the great apex suit that continued for years. In Bulletin 601 of the U. S. Geological Survey the geology and mineral deposits of the National mining district are described by Waldemar Lindgren. The area is situated near the Oregon state line, on the western slope of the Santa Rosa range (which has had an output of $7,000,000 since 1869), being reached from Winnemucca, 70 miles south, by stage and auto. Gold was discovered in 1907 by J. L. Workman, but the rich shoot was found in the next year. The history of the district is practically one of the National mine, namely, rich ore, high-grading, and apex suits. The mineral deposits at National are narrow fissure veins with a northerly trend and steep east or west dip. They intersect latite, rhyolite, basalt, basalt tuff, and trachyte. They are therefore distinctly later than any rock in the district. None have been extensively developed, save the National vein. The characteristic mineral is stibnite, but veins that contain much of it are usually poor in gold and silver. The veins of the district are essentially silver bearing of moderate value; the gold shoot in the National vein is

a unique occurrence in the district. In the National mine there is good evidence of deposition of secondary sulphides below water-level. The most abundant is marcasite, also pyragyrite and stibnite. The gold deposit was found 40 ft. below the surface, and has been followed on the dip for 800 ft., the stope length being 250 ft. Its output is about $3,500,000,



MAP SHOWING THE NATIONAL DISTRICT; ALSO SEVEN TROUGHS AND ROCHESTER.

partly by local treatment and partly by smelting. The National Mammoth Mining Co. drove three adits near the National mine. In 1911 the National Mines Co. sued the Charleston Hill National Mining Syndicate and the Mammoth Mines Co. for alleged trepass. Well known geologists were retained by both sides, in which the complainant won. The bulletin covers 55 pages with maps and illustrations, and is very interesting.

Shipments of antimony ore from Lovelock last week amounted to 26 tons averaging 50% metal. It was extracted from a property of J. H. Causten, T. Thornberry, and W. Harrigan, near Antelope Springs, 21 miles east of Lovelock.

NEW MEXICO

SANTA FE COUNTY

The Santa Fe Gold & Copper company produced 289,766 lb. of copper in August. The output of 837,577 lb. in three months yielded a profit of $74,130. Copper matte is sent to the A. S. & R. plant at Omaha. Some 4 to 15% ore has recently been opened in the mine. The average of the mine is 2.5%. Some ore contains $1.59 gold per ton. Mining costs $1.75, and smelting $2.37 per ton.

NORTH CAROLINA

YADKIN COUNTY

(Special Correspondence.)—At the Gross and Dixon Gold Mining Co.'s mine the incline shaft is 200 ft. deep. Development continues, and a good deal of ore has been blocked out. Within 60 days the stamp-mill and new cyanide-plant will be in operation.

Cana, September 9.

OREGON

MARION COUNTY

(Special Correspondence.)—The Santiam or Lister River mining district is tucked away in a corner of the Cascades, only about three or four miles from the north and south promontory that makes the Clachamas watershed to the north and the Santiam to the south. This part of the country has been heavily timbered and burned, and is now covered with a heavy growth of underbrush, hence it is hard to prospect. However, it was prospected in the early days, and while the early explorers were chiefly looking for gold, yet they found some promising veius. All of them are heavily mineralized from the surface down, hence they did not show their contents in panning by the first prospectors. The lodes were later taken up by other men, and gradually opened. Among this group is one known as the Consolidated Copper, located about 15 years ago by Hugh Freeland, an old prospector from Butte, Montana. He has driven an adit 190 ft., and the whole face will average $12 or over per ton. A small company was organized by Lotz, Larsen, and associates, and it has taken over the ground on a long lease and bond. A car of ore assaying 20% copper and about $5 per ton gold and silver is being extracted. This ore will be easily treated, and should be in demand at smelters on account of its value as a flux. Four men are at work; this number will be increased from time to time. It is proposed later on to install a flotation plant of 100-ton capacity and concentrate the ore, on account of the great distance from market.

Farther up Gold creek is the Gold Creek Consolidated, where, under the direction of Mr. Ormsby, the camp is fairly busy. The power-house has been altered, and an additional 50-ft. head is available, and all the power necessary for the compressor and other purposes is available. The adit has 600 ft. more to go to cut the vein. Within 30 days there will be a full crew at work.

Farther up the creek is the old Lewis & Clarke property, containing high-grade lead and zinc ores. It is under lease and bond to an old miner. Prospects are good.

Gates, September 11.

TEXAS

The mineral resources of Texas are discussed in Bulletin 365 of the University of Texas at Austin, by William B.

WESTERN TEXAS.

Phillips. With 40 illustrations and index it covers 362 pages. In 1913 the mineral products were listed under 22 general items. The total output in that year was $31,666,910. The total since 1882 is $268,161,519, of which petroleum contributed 40.6%; clay products, 17.9%; coal, 13.3%; cement, 3.7%; silver.

3%; and quicksilver, 0.9%. The publication gives in detail the area, value of property, mineral occurrences, and mine operations in each county: also the law relating to prospecting on school lands, and a great deal of other statistical matter.

Cherokee County

(Special Correspondence.)—It is proposed to re-open the iron deposits at Rusk, also some in Cass county. The University of Texas, in its recently issued Bulletin 365, covers these deposits which are found in an area of 1250 to 1300 miles.

Austin, September 10.

El Paso County

(Special Correspondence.)—As evidence of the activity in the mineral region of the Southwest, from which the smelter of the American Smelting & Refining Co. at El Paso draws its ore supply, it is officially announced that plans have been adopted for making improvements and additions to that plant at a cost of about $300,000. The most important feature of the proposed work is three large converters, which will increase the converter capacity about 33%. The new converters will be of steel, lined with brick, each 30 ft. long, and with an outside diameter of 15 ft. Large electric cranes, to carry the molten metal from the furnaces to the converters, will be installed. They will replace the steam tramways which are now in use. Plans are being drawn for a new smokestack 300 ft. high. It will probably be built of brick. A dust-chamber will be constructed.

El Paso, August 26.

UTAH

Juab County

Tintic mines produced 121 cars of ore last week. The use of electric power for hoisting, pumping, milling, and other purposes in this district is rapidly extending. Large motors are at work, and are to be installed. The Utah Power Co. supplies current. Leasing is profitable and popular at Tintic at present, and several hundred lessees are at work. As much as $1600 has been received for a single car of zinc ore. Some rich silver-gold-lead ore has been opened in the Yankee Consolidated. A depth of 1300 ft. has been reached in the Tintic Standard.

Salt Lake County

The Alta Prince adit, Little Cottonwood district, is in 1000 ft., the ground being white limestone containing galena. The objective point is the intersection of the Prince of Wales fissure with the contact between white and blue limestone.——Better ore is showing in the raise on the Toledo fissure in the Columbus Extension.——A recent shipment from the Wasatch mine assayed 70.7 oz. silver, 16.2% lead, 10.9% copper, 18.4% zinc, 6.6% iron, and 0.01 oz. gold per ton. This came from No. 2 workings on the Brain fissure.——On September 25 the Cardiff company paid its initial dividend, 25c. per share or $125,000. The rich ore was cut last October, and has been opened for 225 ft. Daily shipments are 125 tons.——Last week J. Hendrickson and A. E. Eikrem put on oxygen apparatus and went into the Alta-Quincy adit to repair an air pipe, to allow air to go into the Albion mine, where gas had accumulated. Both were overcome with gas, the latter was rescued but the former was found dead. A large quantity of water is flowing from the face of the drift.

The Utah Metal & Tunnel Co. at Bingham is mining 125 tons of $16 lead-silver and gold ores per day. Work is being done 1200 ft. in from the Bingham entrance of the 13,000-ft. tunnel connecting upper Bingham with the Tooele side of the mountain. The shoot is in limestone.

Summit County

A total of $326,250 will be paid in dividends by Park City companies on October 1. Details are as follows: Daly-Judge, 20c. per share, $75,000; Silver King Coalition, 15c., $187,500; and Silver King Consolidated, 10c., $63,750.

WASHINGTON

Ferry County

(Special Correspondence.)—The Midget Gold Mining & Milling Co. has leased the Tom Thumb mine, one of the most valuable properties in the Republic district, for three years, to Z. E. Merrill. Under the superintendency of E. J. Delbridge the mine is being unwatered, and needed repairs are being made. The roadbed of a Great Northern railway spur from the Ben Hur mine, two miles, to the Tom Thumb is being re-ballasted, and the track re-laid for the transportation of ore from the latter to the smelters. It was estimated that the Tom Thumb had approximately 10,000 tons of ore opened, valued at $10 per ton, when it was closed five years ago for want of local treatment. The property is well equipped with hoisting and pumping machinery, air-compressor, and electric-light plant. In September, 1909, J. L. Harper took a lease and option on the property for the New Republic company, and operated it for a few months, and in the following spring sub-let it to other people. During this time about 25,000 tons of ore was mined and shipped. The Tom Thumb is opened by an incline shaft on the vein, a vertical working shaft, down over 400 ft., a cross-cut on the 230-ft. level, drifts on the vein connecting the old and new workings, and much other development work. The workings will admit of 15 to 20 men being employed to advantage on each shift. The mine is situated at the extreme north end of Republic and the leasing operations will be of importance to the district.

Republic, September 17.

Thirty-seven tons of ore from the Knob Hill mine sent to the Trail smelter returned 2.4 oz. gold and 7.2 oz. silver per ton, and a net profit of $1545. Nine cars of similar ore are on the way to the smelter. Average monthly profit this year is $10,000.

Stevens County

The Norman Mines Co., of which Sidney Norman of Spokane is manager, has taken over the Great Western property, adjoining the Last Chance mine, seven miles from Northport. The mine has produced lead worth $500,000.——The Blue Star Mining Co. of Chewelah, owning the old Eagle Lode claim and other properties at Chewelah, has bonded all of its claims to Cecil R. Gould of New York for $60,000. Mr. Gould has also purchased the properties of the New Currency Mining Co. of Chewelah for $30,000.

CANADA

Alberta

The mineral production of this Province in 1914 totaled $12,684,234, against $15,054,046 in 1913. Coal accounted for $9,350,392, natural gas; $1,214,670; cement, $1,212,342; and gold, $992. The Province contributes about 9% of the total of the Dominion.

Between Banff and Laggan, the Alberta Copper Co. has acquired six claims containing good ore, 3000 ft. above the Canadian Pacific railroad. An aerial tram is to be erected.

British Columbia

The Annual Report of the Minister of Mines, Richard McBride, and that of the provincial mineralogist, William Fleet Robertson, for the year 1914, is just to hand. In its 544 pages and illustrations a great deal of valuable information is available. The mineral output was valued at $26,388,825, a decrease of nearly $4,000,000 due to the state of metal market late in the year.

The Granby Consolidated company's smelters are at full capacity, according to the general manager, Frank M. Sylvester. With eight furnaces in blast the Grand Forks plant is treating 100,000 tons of ore per month; with four at Anyox the quantity is nearly 80,000 tons. Over 850 men are employed at the latter property. The Mamie mine on Prince of Wales island is supplying some ore for the smelter, also the Midas mine at Valdez. The company is encouraging miners in north-

ern British Columbia and Alaska as much as possible, but not much custom ore has been received. About the only considerable shipper has been the Rocher de Boule mine near Hazelton, which sent 6000 tons in the last two months.

On October 10 the Standard Silver-Lead company of Silverton will pay 2½c. per share, equal to $50,000. This makes $100,000 for the year, and $1,650,000 to date.

The Provincial government is to aid financially the concern that is establishing a zinc smelter at Nelson. The old Fairview plant will be used.

ONTARIO

A train that left Cochrane for the Kowkash goldfield on September 8 was crowded with prospectors, also a box-car full of canoes. A train that came in from the west carried returning prospectors. They consider the rush not warranted. An official of one of the Porcupine companies was pessimistic on his return. He said there was no rock to prospect, but nearly all muskeg (a swamp). Others are optimistic, bringing back rich samples of ore.

During August the Nipissing high-grade mill treated 139 tons of ore, while this and the low-grade plant yielded silver worth $179,048. It is considered probable that the Cobalt Lake fault will be found in Nipissing ground at depth.

The Alexo nickel mine at Porquis Junction produced 766 tons of ore in August.

During the period ended August 12 the Hollinger mill treated 29,955 tons of ore averaging $9.03 per ton. Operating costs were $3.287 per ton, and gross profit $147,289.

An incline shaft is to be sunk at the Dome mine, as the present main shaft is in ore, making operation awkward. Good developments are reported from 700 ft. depth.

The new Schumacher mill is working satisfactorily.

YUKON

A great deal of road repairing has been done in the Dawson district this season by the Government. Some roads have been widened to 24 and 30 ft., with good crowns in the centre.

The Mayo silver-lead field is developing well. More prospectors are wanted, not men looking for work. At a banquet at Mayo last month to Alfred Thompson, member of parliament, the meat, vegetables, and flowers were Yukon products.

MEXICO

(Telegraphic Correspondence.)—Instructions State Department to consuls Villa territory urging all Americans and other foreigners leave has resulted in smelters, mines, industries, closing down. Foreign employees have left, Mexican employees discharged, excepting few watchmen or few cases moderate development continuing. Velardena smelter and mines, Mapimi, Chihuahua, Santa Eulalia mines and smelter at Terrazas station, mines Cusi district and others in western part of State all closed. Consuls, merchants, and nearly all American citizens are out or coming out from towns. Train service irregular, country quiet, no disturbances, and order preserved.

El Paso, Texas, September 22.

DURANGO

A consolidation has been effected of the Candelaria, the Contra Estaca and LaPuerta, and the Pilar mines in the San Dimas district. The new officers are D. M. Burns, president; Forest B. Caldwell, vice-president and general manager; and Charles Dunphy, secretary. Included in the above merger is also the San Dimas Power Co., which has prepared plans for the erection of a hydro-electric power-plant with necessary transmission-lines to serve all of the above mines. The present equipment consists of a 110-ton mill at the Candelaria, and one of equal capacity at the Estaca. The ores are silver-bearing, and the all-sliming process is used, employing the Dorr counter-current system with Oliver vacuum-filters. The offices of the company are in the Crocker building, San Francisco, and the Mexican address is San Dimas, Durango, Mexico. Mazatlan is the port of entry.

PERSONAL

J. R. FINLAY is at Butte.

ALBERT BURCH has returned from Butte.

F. L. RANSOME was at Goldfield recently.

LEO VON ROSENBERG is in Eastern Oregon.

F. LYNWOOD GARRISON has gone to Tucson.

KIRBY THOMAS was at Pioche, Nevada, recently.

H. E. WEST has returned to Berkeley from Peru.

CHARLES WILL WRIGHT has returned to Sardinia, Italy.

CHARLES S. HERZIG is in the San Juan region of Colorado.

J. C. GREENWAY, from Warren, Arizona, is at the Fairmont hotel.

HARRY L. DAY, of Wallace, Idaho, is attending the Mining Congress.

W. L. HONNOLD is now working with the Belgian Relief Commission.

BEN. B. LAWRENCE is due at Spokane on October 1, and later in San Francisco.

GEORGE A. DENNY reached Liverpool on August 30, on his return from Mexico.

WILLIAM H. KNOWLES, of Sonora, California, formerly in Colorado, was here last week.

GEORGE M. RICHARDS has returned from a three years' reconnaissance in the Belgian Congo.

H. R. VAN WAGENEN is expected in San Francisco, from Pioche, Nevada, early in October.

P. B. MCDONALD will join the editorial staff of the MINING AND SCIENTIFIC PRESS at the end of the current month.

H. FOSTER BAIN was in Cornwall early in September, where he read a paper before the Royal Cornwall Polytechnic Society.

J. J. CARRIGAN, Safety-First engineer for the Anaconda company, has been attending the First-Aid contest at the Exposition.

JAMES CALLAHAN, a pioneer of the Coeur d'Alene, Idaho, and a large shareholder in the Interstate-Callahan zinc mine, is ill at Wallace.

F. C. NEWTON has resigned the superintendency of the Perth Amboy smelter to become manager for the Newton Manufacturing Co., at Lowell, Mass.

GUY C. RIDDELL has returned to East Helena, after a month spent in inspecting smelting plants in the Middle Western and Rocky Mountain states.

W. RAY COX, who for several years has been a Mineral Inspector of the General Land Office at Portland, Oregon, has been appointed Professor of Mining and Metallurgy in the School of Mines at the Oregon Agricultural College, Corvallis, Oregon.

J. H. FARRELL has resigned the position of consulting engineer to the Yellow Aster Mining & Milling Co. He directed development work at the Yellow Aster mine for a year following the completion of a geological examination of the Randsburg property.

Schools and Societies

The Cobalt branch of the CANADIAN MINING INSTITUTE entertained the Porcupine branch last week.

The INDUSTRIAL ACCIDENT COMMISSION will hold the second public hearing to consider mine-safety rules for California today, September 25, at 407 Underwood building, 525 Market street, San Francisco, commencing at 9:30 a.m. At the hearing which was held on June 11, 12, and 14, a number of sections were sent back to the committee to be re-drafted. Most of the discussions will be on these re-drafted sections.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, September 23.

Antimony	35 —35¾
Electrolytic copper	18½—18¾
Pig lead	4.75—5.70
Quicksilver (per flask)	$90
Spelter	17 —17¼
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	29

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, September 23.—Copper is quiet but firm; the lead market is dull though steady; zinc is firm owing to scarcity, futures neglected.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	13.60	19.75	Dec.	12.75	....

Exports of copper during the week ended September 4 totaled 4,033,092 lb., valued at $714,882. Of this, 1,782,452 went to France, 1,338,642 to England, 467,684 to Norway, and 360,757 to Denmark. Imports amounted to 4,187,155 lb. worth $569,011. Canada sent 1,871,555; Cuba, 1,232,000; and Chile, 1,136,000 pounds.

It is considered that the production of metal in the United States exceeds domestic consumption and exports by 24,000,000 lb. per month, and new producers are making large outputs.

In the quarter ended August 31 the Kennecott properties, Alaska, yielded 23,000,000 lb., with a net profit of about $3,250,000. Some 70% ore has been sent to Garfield, Utah. Braden yielded 2,858,000 lb. for 8 months of 1915, against 18,315,000 lb. in 1913. The Champion company, Michigan, is to pay $2 per share, making $21 since January.

The American Smelting & Refining Co.'s report for the first half of the current year is to hand. The net income available for dividends was $5,019,982, an increase of $53,290 over that period of 1914.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

June	56.43	49.03	Dec.	49.27	....

The silver market is showing a better undertone. This may be due to purchases by the United States Mint, 4,375,000 oz. having been bought since August 1, an amount equal to the total bought in 1914. The recent rise in prices resulted in 486,929 oz. leaving Cobalt last week, making a total of 6,068,538 oz. for the year, also an increase in ore shipments. About 240,000 oz. arrived in San Francisco from Mexico last week. London advice states that supplies are restricted, partly due to the low rate of exchange two weeks ago. Continental purchasers have increased.

Since the beginning of the War 10,800,000 oz. silver has been coined in Germany. The 'Frankfurt Gazette' reports that only 18 marks per head of population has been coined out of M20 authorized. This metal is said to be from German mines.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Aug. 25	95.00	Sept. 8	95.00
Sept. 1	95.00	" 15	90.00
		" 22	90.00

Prices for ore at Joplin showed little change last week. The output of the Missouri-Kansas-Oklahoma region was as follows: blende, 5059; calamine, 335; and lead, 977 tons, averaging $71.49, $61.23, and $49.91 per ton respectively. The total value was $430,939, and for 38 weeks, $16,690,765.

Tin is dull at 32.50 to 33c. per pound, and £152 per ton in London.

ANTIMONY

Efforts to move a surplus of stock in dealers' hands has caused an easier market, and the range of quotations is about 27.50 to 28.50c., duty paid. For metal in bond 26c. is asked, equal to 28.50c. There seem to have been no results from the large export inquiries reported from time to time. The quotations are confined to Chinese and Japanese grades.

Eastern Metal Market

New York, September 17.

The metal trade in general is quiet and awaiting developments. It is generally admitted that much depends on a favorable outcome of the efforts to establish Anglo-French credit through the medium of the much-discussed and enormous loan. Meanwhile, sellers are marking time. Copper advanced abruptly fully ½c. September 14, and today is strong at 17.87½c. cash, New York, partly because of advances at London and partly on account of the strike of several thousand miners in Arizona. Incidentally it may be remarked that strikes are causing industrial distress in many directions, Bridgeport, Connecticut, has recovered from the trouble; but serious conditions prevail in other parts of New England. A Providence, Rhode Island, builder of machine-tools closed his factory when his men walked out, and it has been idle for weeks. Half a dozen plants in northern New Jersey are hard hit, and manufacturers everywhere are worried. The usual demands are for recognition of the Union, 10% increase in wages, and the eight-hour day. Zinc has been dull, with a tendency on the part of all but very choice grades to decline. Lead has been quiet, and price cutting has been halted by a reduction to 4.50c., New York. Tin has been extremely dull, with spot and futures at the same level. Antimony is a trifle weaker because of pressure to unload surplus stocks. Aluminum is scarce, and the nominal prices range from 45 to 50 cents.

The great demand and high prices paid for semi-finished steel and steel rounds has aroused the interest of the railroads, and started them wondering how their 1916 requirements are to be filled. It is estimated that the inquiry for first-quarter delivery of billets, blooms, and large rounds totals about 200,000 tons. Jobbing iron foundries are doing better, but are not as busy as they should be, and they are slow in buying pig-iron at recently advanced prices. The demand for machine-tools continues heavy, despite the far-off deliveries. Lathes continue to be the most active; but it is noticeable that the call is now for the larger sizes such as are used in making big shells.

COPPER

The market was dull and easy, with electrolytic quoted at 17.25c., cash, New York, until September 14; but on that day there occurred one of the sudden changes now characteristic of all the metals. Electrolytic jumped to 17.75 to 18c., 30 days, delivered, and September 17, it was held at 17.87½c. cash. On the day of the first advance producers sold a few thousand tons at full prices, but it was influences other than buying that gave the market its strength. One of these was the strike of several thousand workers of various kinds at the mines of the Arizona, Detroit, and Shannon copper companies in Arizona, following a refusal to pay higher wages, and the other consisted of advances in the London quotations for electrolytic. The London price advanced on September 14, £1 10s. on the 15th, and 10s. on the 16th, making the quotation £86 10s., equivalent to 18c. delivered at London. The reason for the strength abroad appeared to be an optimistic view of the efforts being made to float a large Anglo-French loan in this country, thereby establishing a credit against which the Allies can continue their purchasing in the United States, without further upsetting our financial equilibrium. The favorable outcome of negotiations in this direction was anticipated, also, by an advance in the foreign exchange market, the pound sterling rate advancing on September 17 to $4.72⅜. French money advanced proportionately. Once an Anglo-French credit is established, a decided change in the attitude of English and French purchasers is looked for, and that this is badly needed is indicated by the fact that copper exports September 1 to 18 totaled only 5427 tons. The following comparative statement of copper exports (in long tons) from the United States during the eight months of this year was compiled by C. Mayer, secretary of the New York Metal Exchange:

Country	1915	1914
United Kingdom	57,015	55,902
France	62,592	47,322
Germany	.....	88,452
Holland	798	51,391
Belgium	.....	2,876
Austria	.....	13,809
Italy	27,916	10,460
Denmark	1,550	.....
Norway and Sweden	11,586	.....
Russia	8,651	125
China and Japan	81	1,640
Sundries	1,597	1,388
Total	171,786	273,365

The consumption of copper in the industrial arts is far from good. For months it has been practically the War demand that has sustained the trade. Lake is quoted at 18c., and a business of several million pounds has been done at that figure.

ZINC

Despite the presence in the market of a few export inquiries, zinc has been dull and easy almost continuously. As with all the metals there is much waiting on the outcome of the foreign loan negotations. The New York quotation on September 16 was 13.75c., prompt shipment, with St. Louis at ⅛c. less. Last quarter shipment was quoted at 13c., and brass-mill special at 16c. A sale of Horsehead was made this week at 40c., showing that the premium for very choice brands is not impaired. Some inquiry for nearby delivery developed on September 16, but sellers were not eager for orders at the prevailing prices. There is a general feeling that production is outpacing consumption; this has a depressing effect. Again the demand for galvanized sheets is not good, and this is not favorable for ordinary prime Western metal. The foreign market has been weak. The exports September 1 to 18 amounted to 1988 tons.

LEAD

The A. S. & R. Co., which on September 9 cut its New York quotation from 4.80 to 4.70c., a reduction of $4 per ton, put a quietus on price cutting on September 14 by making another and similar reduction, thereby bringing the price down $8 per ton in the course of a week. After the quotation touched 4.50c. independents withdrew from the market, except at the figure of the leading interest, and quiet ensued. Except for some fair-sized sales to Japan there was no business stirring. It is notable that New York now watches London conditions in lead rather than those at St. Louis. Until consumers rid themselves of some of the high-priced lead they bought on the recent rises there is no expectation of any large domestic business. Exports from September 1 to 18, totaled 953 tons.

TIN

Dealers and large consumers are exasperated by the greater restrictions placed by Great Britain on trading in tin, but realize that the English hold the whip hand, and that all they can do is to comply. For days there has been no business worth mentioning, and the spot quotation continues to hover between 33 and 33.62½c. Spot and futures are offered at the same price. The London market has been as dull as that here, largely because no orders were received from the United States. Arrivals for the month up to September 18 totaled 2998 tons, and there was afloat on that day 4210 tons.

COMPANY REPORTS

JUMBO EXTENSION MINING COMPANY

During the past year or so this Goldfield company has attracted considerable interest. The report covers the year ended Jnne 30, 1915. The general superintendent, J. K. Turner, makes the following remarks: The area of the property remains at 97.447 acres of patented claims, including the Velvet of 17.421 acres. Development amounted to 5874 ft., costing $9.89 per foot. Of this, 1354 ft. was done in the Polverde claim. Cross-cuts are under way in a southerly direction at 932 ft. depth. The downward extension of the 524 orebody in the Velvet was 100 ft. south of the Polverde-Velvet side-line, in a raise from the 932-ft. level. A large quantity of ore will be mined from this area. The claim produced 1429 tons of $76.26 shipping ore, and 3284 tons of $15.17 mill ore. Development in the Velvet totaled 4520 ft. A new shale-latite orebody was found near the Polverde-Velvet side-line at 880 ft. depth. The upward extension was proved for 100 ft. and downward is exposed in the raise from 1017 ft. Intermediate-level drifts show continuity between these points. A large tonnage is expected from this area. The shale orebody has been proved from 952 to 1017 ft. Stoping is in progress between the 975 and 964-ft. levels. Both veins lie very flat, an average dip of 27° from the horizontal, this accounting for the short vertical distance between levels. To facilitate general exploration it was decided to enlarge the Velvet shaft, and sink it to 1000 ft. This should be finished by January 1, 1916. The Velvet claim yielded 9049 tons of $74.14 and 2546 tons of $11.14 ore. Ore reserves are estimated at a total of 86,750 tons at $41.21 for shipping and $7 for milling ore.

In June 1914 the Bonnie Claire mill, leased to the company, was closed, and arrangements were made with the Goldfield Consolidated company to treat ore, up to September 10, 1914. The low-grade copper-gold ore is not suitable for the mill, so experiments, mentioned in the PRESS, are being made on this ore. A total of 10,873 tons of dry ore was shipped, valued at $669,560 gross. Tailing and smelter losses amounted to $51,161, leaving $618,399 net value, or, in terms per ton. $61.58, $4.71, and $56.87, respectively. The Consolidated mill treated 5547 tons of ore valued at $81,851 gross, and $32,549 net. The total yield was $650,948, or $39.64 per ton, and net realization $339,373. Two dividends of 5c. each amounted to $125,000; litigation, $11,351; balance of purchase of Velvet claim, $50,000; and settlement of side-line agreement with the Reorganized Booth company, $15,000. The cash balance on June 30, 1915, was $120,533, against $29,100 at the end of the previous year. On September 1 a distribution of 7½c. per share was made, leaving a surplus of $200,000, which is to be maintained.

BROKEN HILL SOUTH SILVER MINING COMPANY

The report of this company covers the half-year ended June 30, 1915. It may be summarized as follows:

Loss of time due to the War affecting sales of lead, days	42
Men employed, average attendance	1,167
Development, feet	3,707
Ore extracted, tons (14.9% Pb, 14.7% Zn, 7.5 oz. Ag)	131,059
Concentrate recovered, tons (61.2% Pb, 9.7% Zn, 22.2 oz. Ag)	24,961
Cost per ton of ore	$4.86
Revenue from production and sale of zinc tailing	$1,378,000
Operating profit	735,000
Amount available, including previous balance	1,858,000
Dividend No. 61	144,000
Metals unsold and concentrates on hand	1,065,000

Development was satisfactory. The mine is 1470 ft. deep.

MINING DECISIONS

MINER'S LIEN—NON-RESPONSIBILITY OF OWNER

An owner of mining property posted, but failed to record a notice of non-responsibility for work and labor performed at the instance and request of an optionee. Persons performing labor on the claim with the full knowledge that the owner would not be responsible and relying solely on the agreement and credit of the optionee are not entitled to a lien for wages.

Street *v.* Hazzard (California), 149 Pacific, 770. April 27, 1915.

OIL LEASE—EFFECT OF ASSIGNMENT

A, owning an oil lease, assigns one-half thereof to B, on condition that B will bear all the expenses of drilling, equipping, and operating the oil-wells to be drilled thereon. B assigns three-fourths of his interest to C on the same condition. C assigns one-eighth of his interest to D "subject to the terms and conditions of the lease from A to B." Held, that D was liable under his assignment for payment of only one-eighth of the development expenses.

Cox *v.* Butts (Oklahoma), 149 Pacific, 1090. June 8, 1915.

CHARACTER OF LAND—EFFECT OF DEFAULT JUDGMENT

While a judgment on default in favor of the mineral claimant in a proceeding between a mineral and an agricultural claimant involving the character of the land in dispute, renders the question as to the character of the land *res judicata* between the parties, it will not be accepted as establishing the character of the land as between the Government and the mineral claimant, and constitutes no bar to further inquiry as to the character of the land involved.

Bailey *v.* Molson Gold Mining Co. (Land Department), 43 Land Decisions, 502. December 16, 1914.

CONVEYANCE OF MINERALS—CONSTRUCTION

Where a conveyance of mineral rights contained the clause, "together with the right to mine said coal and other minerals, the right to use all necessary timber and water for such mining purposes, the right-of-way for all necessary roads, and all other rights and privileges which may be necessary for the proper mining and transportation of said minerals," this clause was held to entitle the grantee to use an air-shaft and fans constructed on the surface and trani-lines underneath the snrface for the purpose of mining coal underneath other lands, in connection with their use for mining coal underneath the lands in question. This rule would not, however, apply to mere lessees of land, or of the surface.

Bagley *v.* Republic Iron & Steel Co. (Alabama), 69 Southern, 17. June 3, 1915.

COAL LEASE—UNAUTHORIZED USE OF PREMISES

A coal lessee covenanted in his lease that he would not nse the premises "for any other purpose than that authorized in this lease, nor allow them to be used for any other purpose." Subsequently the lessee proceeded to sink shafts on the premises from which he extended drifts into the adjacent lands, from which he mined large quantities of coal and removed them through such drifts and shafts. Held, that the lessee should be enjoined from using the leased premises to mine coal beneath other lands, as the lessor would be entitled to no royalties from such coal, and such unauthorized use of the premises would amount to a violation of the covenant above recited.

Sharum *v.* Whitehead Coal Mining Co. (Oklahoma), 223 Federal, 282. April 14, 1915.

BOOK REVIEWS

Properties of Steam and Ammonia. By G. A. Goodenough. P. 108. Charts. John Wiley & Sons, Inc., New York, 1915. For sale by the Mining and Scientific Press. Price, $1.25.

This is a technical study involving thermo-dynamics. Recent investigations on the properties of saturated and superheated steam have resulted in accurate data on the whole subject. Work on ammonia is not so well advanced. The laws governing certain changes in these vapors are explained. There are 74 pages of tables on the properties of steam and ammonia.

Laboratory Work for Coal-Mining Students. By J. Sim and A. M. Wylie. P. 136. Ill., index. Edward Arnold, London, 1915. For sale by the Mining and Scientific Press. Price, 90 cents.

A metal-mining engineer is trained to be able to determine the composition and value of the various ores he meets with; so should the coal-mining engineer be conversant with the mineral he is responsible for extracting. Coal is sold on more exacting terms than formerly, hence the necessity for a thorough knowledge of it. Little has been published on the subject in text-books. The volume under review includes full details of sampling and coal analysis, washing and coking tests on coal, testing of oils, and gas analysis. Chapter V deals with the rather complex subject of fan tests, and the laws of ventilation.

Metallurgical Analysis. Brief course in. By Henry Ziegel. P. 66. The Chemical Publishing Co., Easton, Pennsylvania, 1915. For sale by the Mining and Scientific Press. Price, $1.

This book consists of a collection of standard analyses in daily use in many laboratories. It was written for upper class men, trained in elementary qualitative and quantitative analysis, and who are able to work out problems in chemical arithmetic. Every other page is blank, but ruled for notes on work done. Iron ores, iron and steel; limestones, slags, and clays; non-ferrous alloys; and non-ferrous ores and matte are the main heads of chapters. The methods of analysis are generally rapid.

Transactions of the American Institute of Metals. Vol. VIII. Edited by Charles Vickers. P. 394, and six bulletins. Illustrated. American Institute of Metals, Buffalo, New York, 1915. For sale by the Mining and Scientific Press. Price, $5.

The members of this society devote themselves to the base-metal industry, and in this volume the following subjects are discussed: 'Safety and Sanitation in the Brass Foundry,' 'Progress in the Nomenclature of Alloys,' 'Some Recent Applications of Metallic Cobalt,' 'Drop-Pouring of Casting,' 'Bull Run Talc,' 'Modern Die-Casting Practice,' 'Aluminum Die-Castings,' 'The Care and Conversion of Rolling-Mill Scrap,' 'A Brief Visit to a Brass Rolling-Mill', 'A Hot Shortness Testing Machine for Aluminum Alloys,' 'Making Aluminum Test Specimens on Castings,' 'Failures of Forgible Bars,' 'New Method for the Determination of Zinc in Alloys,' 'Brinell Hardness Testing of Non-Ferrous Alloys,' 'The Commercial Classification of Refined Copper,' 'Spelter-Manufacture and Properties,' 'The Metallurgy of Tin and Antimony,' 'Effects of Repeated Re-Melting of Copper,' 'Tests on Electric Furnaces for Brass Foundries,' 'Electric Furnace for Medium Temperature,' 'Electric Brass Melting,' 'Use of Producer-Gas for Melting Yellow Brass,' 'Pyrometers for Molten Brass and Bronze,' and a report of official chemists of the American Institute of Metals. This list of papers and discussions by members should give an idea of the value of the publication.

The Theory and Practice of Ore Dressing. By Edward S. Wiard. P. 420. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by Mining and Scientific Press. Price $4.

The art of ore-dressing has developed so rapidly and has experienced so many fundamental changes in the last few years that an up-to-date treatise on the subject as applied at metalliferous mines in Western America, written from the standpoint of the author's practical experience as a mill superintendent and designer of mills in various districts of the Western United States and Mexico, makes a timely addition to the technical literature. The author acknowledges the benefit received from personal contact with Professor Richards as a teacher and is appreciative of the immense amount of information contained in Richards' encyclopedic volume. The arrangement of the subject-matter is novel and pleasing. The book makes a good impression from the first and appeals to one as a business-like treatise on Western practice. The many working drawings are a distinct feature; the illustrations are good, clear, and not too greatly reduced in scale. The book will appeal to the mining engineer, to the metallurgist, and to the student. In the hands of an experienced teacher it should be useful as a text-book. What little working theory has been developed to date on ore-dressing is stated briefly but clearly. A single volume of 400 pages necessarily imposes limitations and the author has selected wisely without over-stepping the domain of metallurgy. Amalgamation, therefore, is not mentioned and stamps have received scant consideration. The author is to be complimented on having produced on the whole a fairly well balanced book with an unusual proportion of valuable new information.—C. E. Van B.

History of the Panama Canal, its Construction, and Builders. By Ira E. Bennett. P. XI, 543. Ill., index. Historical Publishing Co., Washington, D. C., 1915. For sale by Mining and Scientific Press. Price, cloth, $5; half leather, $10; full leather, $20.

This book is the product of over three years' labor by the author and his collaborators. Written in Washington, where the men who planned, directed, and built the Canal were always accessible, the History was prepared under exceptionally favorable conditions. The work deals with the history of Panama from earliest days to the completion of the Canal; gives an account of diplomatic and legislative tangles—all the treaties relating to the Canal are contained in the appendix. Among the special contributors are the former chief engineers of the Canal, John F. Wallace and John F. Stevens. Theodore Roosevelt tells how the United States acquired the right to dig the Canal. The justice of his interfering in the quarrel between Colombia and Panama—he simply notified Colombia that it would not be permitted to land troops in Panama—is a subject about which future historians are likely to differ. There is much to interest the engineer in the figures given for the cost of excavating and amount of explosives used, and in the description of the dredges. The Commissary Department and sanitation work is briefly described, and the troubles with the housing of the gold and silver employees is lightly touched. In a recent magazine article, the chief engineer, G. W. Goethals, writes feelingly of the difficulties that he had in adjusting the disputes between the wives of the members of his force; he found the satisfying of these ladies more difficult than the engineering problems of canal construction.

Taking the book as a whole it must be considered as frankly disappointing. The first 13 chapters seem a compilation of historical data from easily accessible sources. No foot-notes, references, or bibliography are given. The publication of the statements of interested parties such as those in Chapters XXXV to XLIX is useful, but critical comment is greatly needed. One map only, and that of no great excellence, is provided. The index seems complete. Pages 322 to 461 are devoted to 'American Industries and the Canal'; much useful information is contained in these pages. If the opinions given

are unbiased they are of extreme utility. But it seems a suspicious circumstance to find, as a rule, only one article of a kind selected for praise. For instance, there seems no special reason why one variety of the multitudinous hosiery that all haberdashers display should be so warmly eulogized; nor, although we are familiar with the article, can we see any superlative quality in the special brand of underwear so highly extolled. These invidious distinctions smell strongly of paid advertising. But when we find in pages 422 to 430 a page and a half devoted to fulsome praise of one brand of cereal, which is mentioned by name 17 times, we feel that the hand of the writers of concealed advertisements has lost its cunning, and we should have been more impressed if the word 'advertisement' had been printed at the bottom of the page. W. H. S.

Monazite, Thorium, and Mesothorium. By Karl L. Kithil. *Technical Paper* 110. *Mineral Technology* 8. P. 32. Plan. An abstract of this appeared in the Press of August 28.

The Buying and Selling of Ores and Metallurgical Products. By Charles H. Fulton. *Technical Paper* 83. P. 42. This is a valuable paper, and an abstract appeared in the Press of September 11.

Gay Gulch and Skookum Meteorite. By R. A. A. Johnston. Museum Bulletin 15. Geological series. P. 31. Ill., 11 plates, map. Department of Mines, Ottawa, Canada, 1915.

Salt Deposits of Canada and the Salt Industry. By L. Heber Cole. P. 160. Ill., maps, index. Department of Mines. Ottawa, Canada, 1915. This should be of interest to salt men in California.

Value of the High-Pressure Steam Test of Portland Cements. By R. J. Wig and H. A. Davis. Bulletin 47. P. 34. Ill. Technologic paper of the Bureau of Standards, Washington, D. C., 1915.

Wind Stresses in the Steel Frames of Office Buildings. By W. M. Wilson and G. A. Maney. Bulletin 80. Engineering Experiment Station of University of Illinois. P. 88. Plans. Urbana, Illinois.

Mineral Resources of Texas. By William B. Phillips. Bulletin 365, scientific series No. 29. P. 362. Ill., index. University of Texas, Austin, 1915. The mineral output of this State is worth over $30,000,000 per year. An abstract will appear in another issue of the Press.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Wood Pipe for Explosion Tests

During the first-aid and mine-rescue contests at the Exposition this week, several coal-mine explosions were shown. For this purpose the Pacific Tank & Pipe Co., of San Francisco, constructed on the Marina a 72 in. fir stave-pipe 110 ft. long, to be used as the coal-dust explosion-gallery. This pipe consists of staves milled of fir lumber, dressed 2¾-in. thick and banded with ⅞-in. bands furnished in two pieces. The lower end of the gallery is banded for 25-lb. pressure; the pressure resulting from these explosions being approximately from 12 to 15 lb., which gradually diminishes to zero at the open end. The bands are spaced farther apart as the open end of the gallery is approached. In the wooden gallery constructed to represent mining conditions, finely divided coal-dust was shown to be explosive. A miners' charge of black blasting-powder was fired from a cannon into the gallery, representing a windy shot. The flame of a charge of this powder is long, hot, and of considerable duration, and gives sufficient heat to fire the dust and start an explosion propagating through the gallery. The U. S. Bureau of Mines wished to demonstrate to visitors at the Exposition the inflammability of certain kinds of coal dust.

Commercial Paragraphs

Bulletins 600 and 1000 of the Pacific Electric Manufacturing Co., San Francisco, deal with high-tension switches, disconnecting switches in the former, and fused isolating links in the latter.

Flotation Oil Circular No. 7 of the Pensacola Tar & Turpentine Co., Gull Point, Florida, discusses its products with frothing and selective qualities. Prices are given for 12 oils, retail or in bulk.

The Mable Mining, Milling & Power Co., Knik, Alaska, has given the Denver Quartz Mill & Crusher Co., of Denver, Colorado, an order for the equipment for a free-milling plant, consisting of one steel crusher, one ore-feeder, one quartz-mill, amalgamating-plates, etc., made by the company.

The Sterling Motor Truck Co., West Allis, Milwaukee, Wisconsin, has published a large illustrated sheet describing its Sternberg dump-trucks. These are made in five sizes namely, 1500 lb., 2, 3, 5, and 7-ton capacity. The Sterling worm-gear drive type, with motor under hood, is made in 1500 lb., 2 and 3-ton sizes.

A novel method for advertising has been adopted by the Charles A. Schieren Co., makers of leather belting, at its exhibit at the Panama-Pacific Exposition. Each visitor to the Company's booth in the Palace of Machinery, Avenue G and Second street, is given a numbered coupon which gives him an opportunity to secure without charge a Keuffel & Esser slide-rule, six of which will be given away on Machinery Day, September 25.

'The Use and Abuse of Ball and Roller Bearings' is the title of a new 20-page paper by F. J. Jarosch, chief engineer of the Bearings Company of America. The text gives explanations and experiences which help in the selection, mounting, and lubrication of ball and roller-bearings in automobile gears and in all other rotating parts, and is intended to help in detecting the real cause of trouble. Nineteen drawings are used to illustrate the text matter. Mr. Jarosch contributes in a practical way valuable ideas on a much discussed subject. Those interested in the subject may obtain a copy free from the publishers, the Joseph Dixon Crucible Company, Jersey City, New Jersey.

Electric furnaces of the Snyder type are being installed by the Thomas Davidson Manufacturing Co. of Montreal, Canada, and the Canadian Brakeshoe Co. at Sherbrooke. High-grade steel is to be made in them. In a paper read before the American Electrochemical Society at San Francisco on September 16, electric steel costs were discussed by F. T. Snyder, of the Snyder Electric Furnace Co., Chicago.

The American Well Works of Aurora, Illinois, has issued Bulletin 141. It describes methods of constructing large capacity deep wells for irrigation pumping in the great plains, an area extending from Nebraska to near the Mexican boundary. The work of the Company's large-size rotary drilling-machine is shown. Logs are given of several wells drilled. In the Palace of Machinery at the Panama-Pacific Exposition this firm has a full line of its apparatus on view.

The medal of honor for self-contained mine-rescue apparatus has been awarded to Siebe, Gorman & Co., Ltd., by the superior jury of the Panama-Pacific Exposition. H. N. Elmer, general agent, 1140 Monadnock Block, Chicago, has appointed E. D. Bullard & Son, 268 Market street, San Francisco, to be his Pacific Coast agents for the sale of Proto, (Fleuss-Davis patents), self-contained oxygen breathing-apparatus and other first-aid and rescue-equipment manufactured by the company.

Bulletins No. 1096, 1412-A, and 1635 of the Allis-Chalmers Manufacturing Co., Milwaukee, Wisconsin, deal with direct-current motors and generators, types 'K' and 'KC'; crushing-rolls; and the hydro-electric plant of the Cerro de Pasco Mining Co., Peru, respectively. The K motors are designed to meet severe service. The KC is an adjustable speed motor similar in design to the K type. Rolls are being used in larger numbers at mines, and the details of construction are timely. The Cerro de Pasco plant, all of A-C manufacture, consists of three 3750-kva. generators each driven by two 2500-hp. impulse water wheels at an altitude of 12,000 feet.

The Denver Quartz Mill & Crusher Co.'s catalogue No. 12 describes and illustrates its mills, starting with the first one made in 1908. This had seven 300-lb. rolls, weighed a total of 4500 lb., and crushed 10 tons per 24 hours with a consumption of 8 hp. The latest, or No. 3 mill, has four 3200-lb. rolls, weighs 32,000 lb., and crushes 100 tons per day, using 18 hp. A roll-tire from a No. 1 machine crushed hard tungsten ore for six months. It retained its shape even when reduced to 60 lb. from the original 330 lb. Six sizes of steel rock-crushers are made, also a simple ore-feeder of large capacity, and the Kidd placer mining compound riffles.

Continuous counter-current decantation is discussed in Catalogue No. 7 of the Dorr Cyanide Machinery Co., Denver, Colorado. The process consists of operating a series of Dorr continuous thickeners in such a manner that the solids, with a small portion of liquid, pass successively from one thickener to the next, being finally discharged from the last thickener as tailing. The main body of liquid, on the other hand, moves in the opposite direction of the course of the ore and is gradually enriched. By each step of the system a large amount of low-grade solution is mixed with a very small amount of higher-grade solution, so that the value of the solutions entering each successive thickener with the solids is materially reduced. The system is used at the McIntyre, Tonopah Mining, Tough-Oakes, Porcupine-Vipond, Porcupine Crown, Mogul, Tom Reed, Gold Road, Hollinger, and Rochester mills. The last named was described in detail in the Press of August 28.

EDITORIAL

T. A. RICKARD - Editor

PHILIP B. McDONALD has joined the editorial staff of this paper.

THE COST of the War is now estimated at $85,000,000 per day; it will soon be $100,000,000 per day.

ARRANGEMENT of the big loan for the Allies will facilitate dealings in copper and should strengthen the market for that metal.

DIRECTOR of the Mint has purchased 4,375,000 ounces of silver since August 1, or nearly as much as during the whole of last year.

SPEAKING of ore-stealing, as we did last week, it is gratifying to note that a new law in Colorado comes into effect on November 1, whereby every ore-buyer must obtain a license and pay $100 per annum for it. This is intended to check the illicit trade in stolen ore.

FOR the twelve months ending with August the exports from the United States aggregated $3,035,033,280, as against $2,280,185,791 in the previous twelve months. During the same period the excess of exports over imports was $1,365,334,346. Hence imports of gold have increased $184,691,717. These are lordly figures.

ALUMINUM is one of the metals most affected by the War, the price having risen from 17 cents before hostilities began in Europe to 45 cents, at the present time. The output in this country this year is expected to be 50,000 tons, as against 3575 tons in 1900 and 150 pounds in 1885.

ON another page we reproduce the paper presented to the Engineering Congress by Mr. W. R. Ingalls, the editor of the *Engineering and Mining Journal*. It is a pleasure to give our readers this authoritative statement on a subject of such timely interest, for the economics of zinc is one on which Mr. Ingalls is especially qualified to speak.

ACCORDING to a preliminary report by a junior official geologist the Kowkash gold discovery is in Keewatin rocks of a schistose character, traversed by quartz-porphyry dikes. These are normal geologic conditions. Small glassy quartz veins abound, and in one of them a spectacular showing of gold is to be seen. The report does not suggest the addition of a goldfield of any importance to the province of Ontario.

WE TAKE pleasure in publishing part of an address delivered recently before university students by Mr. George Otis Smith, the director of the Geological Survey. It will be found so interesting as to require no explanation for its publication in our pages, but we may confess that one reason for reproducing a large part of this notable utterance is to show our readers what kind of man is directing the scientific activities of the Geological Survey. It is a matter of congratulation that he should be a man of clear insight and wide sympathies, a scholar and a gentleman, as well as a clever geologist and an able executive.

THE miners' strike at Clifton and Morenci, in Arizona, affects 5000 men and stops the production of copper at the rate of 70 million pounds per annum. Apparently it is the purpose of the Western Federation to raise the wages of the Mexican miners on a par with that of the American and other white workers. The companies are willing to treat with the local unions, but they refuse to recognize the Western Federation. That is the main source of trouble.

NEW occasions teach new duties. The War is causing changes so profound in the trade of the world as to require the revision of tariff duties in many countries. Now is the time for a non-party tariff commission. Fresh avenues in trade will be opened; many of the old ones will be closed. Necessity will excite invention to the point of replacing many foreign products with domestic substitutes, in our own country and in others. The world will never be the same as it was before August of last year.

SOME kind friend has sent us a recent issue of the *Cornish Post* in which we find an account of Mr. H. Foster Bain's visit to Falmouth, where he read a paper on 'Prospects for Tin in the United States' before the Royal Cornwall Polytechnic Society. The subject of tin in the United States is much like that of snakes in Ireland, but the smelting of tin concentrate from elsewhere, notably Bolivia, is a live topic, to which Mr. Bain did full justice. He also took part in a notable discussion on 'Cassiterite in Cornish Mill-Products.' This was an explanation and amplification, by Mr. W. H. Trewartha-James, of the painstaking studies made by the late J. J. Beringer, who, as a teacher and metallurgist, had devoted much of his life to the subject. Microscopic examination and elutriation tests proved that the loss of tin on the dressing-floors was due to the escape of "infinitesimally fine particles," beyond the reach of existing methods of wet concentration. As Mr. Trewartha-James suggested, it remains for the Cornish operators either to avoid the making of this elusive slime by altering their crushing apparatus or else to devise a new process. All of which is easier said than done. Those present passed

a resolution advocating the appointment of a commission to investigate the matter. Whether this time-honored way of meeting such a problem will solve it, we may doubt, but we do not doubt the usefulness of Beringer's contribution to technical knowledge. As Aristotle remarked long ago, the first step in any investigation is to ask the right question. In scientific development the first essential is to state the problem. That has been done, thanks to the sustained effort of the tireless worker who has now gone to his long rest, and to the loyal help of his friend. Whatever may happen in tin-dressing, the work of Beringer and Trewartha-James will be associated in honorable memory.

RUMORS of new smelters in the Coeur d'Alene have not been without foundation. We are able to confirm the statement that the Bunker Hill & Sullivan company intends to smelt its own ore. A smelter will be built either at the mine or on the coast, according as an investigation of sites and freight-rates may decide. The product to be treated will be mainly crude lead ore picked from the mill-feed. This ore is practically self-fluxing, only an addition of lime being required. The fuel to be used will be coal either from Utah or Vancouver island. We may add that the mill-products, chiefly concentrate, are under contract at present to the American Smelting & Refining Company, but presumably this part of the Bunker Hill output will go to the new smelter when the existing contract expires. The smelter is to be designed and built by the engineering firm of Bradley, Bruff & Labarthe, of San Francisco. Meanwhile Mr. Harry L. Day, of the Hercules Mining Company, has bought the old smelter at Northport, on the Columbia river, and is now remodeling that plant, having arranged for the refining of his bullion at Pittsburg. These events mark an important departure in the history of the Coeur d'Alene.

SALE of metals by auction is the latest scheme suggested by Mr. W. H. Hughes, the Federal Attorney-General, in order to prevent any coterie from obtaining control of the metals produced within the Australian Commonwealth. His proposal applies particularly to copper, lead, and zinc. The Metal Exchange to be established will be under the direction of the Government. No metals or metallic products are to be permitted to leave the country unless sold under the new regulations. Only members that have been duly registered will be entitled to make purchases. All of which is aimed against the small group of alien metal-merchants who have exercised a not too scrupulous control over the metal markets of Melbourne, London, and Hamburg. The experiment is novel and we shall watch it with keen interest. It is one of those manifestations of State paternalism evoked by the abnormal conditions obtaining during a world-wide war; but like some of the other unexpected results of the Great Unpleasantness, it may have enduring effects. Another episode connected with the Australian metal trade is the dissolution of the contract between the Zinc Corporation and Aron Hirsch & Sohn. This contract, dated August 4, 1914, has been annulled by an English court, for the reason that mere suspension during hostilities rendered it impossible for the plaintiffs to sell their concentrate to persons other than the defendants. However, an appeal has been made, and until that is decided, the Zinc Corporation will not be free. Even then, the company is not likely to erect a smelter of its own in England, where the cost of labor and fuel alike are a deterrent to such an enterprise.

Flotation Patents

We publish a brief review of the application of the physics of flotation to the principal processes patented within the last 30 years. Flotation is not young; in youth it lacked seriousness of purpose, that is all; now it is coming into productive activity. An examination of the brief, and often obscure, wording of the patent claims, followed by the reading of such meagre literature as has appeared amid the smoke of litigation, suggests that the physical principles at the back of the observed facts are not yet understood even by the protagonists of rival claims to the monopoly of the process. At best the progress of flotation has proceeded "by trial and error" or else on a "hit or miss" method to which the adjective 'scientific' is not applicable. That a persistent froth can be produced by several of the schemes of treatment outlined in the various patents is fairly clear, but how much of this desired result is due to the light thrown on the subject by the later operations of the chief patentee is a question that is now within the purview of the courts and will soon be decided by the Court of Last Resort. It is fairly plain that the so-called agitation-froth method as applied at Broken Hill was the outcome of something akin to an accident, by mere ringing of the changes in the quantities of oil, acid, air, and water used in the experiments both in London and Broken Hill; it did not come in the wake of any definite scientific conception of the physical principles involved. That inference is warranted by the evidence given in Court by the group of metallurgists who now claim the privilege of priority. On the other hand, it is only fair to say that while the same or similar results could be obtained by a like variation of older methods of procedure, it is a fact that such results were not obtained—at least, not on a working scale—until aided by recent experience. The controversy over prior rights will be forever confused to the scientific investigator, however the courts of law may decide, because the development of the process as a whole, up to date, has proceeded so largely in the dark, unlighted by a clear conception of the natural laws that govern the metallurgical sequelae. All the claims, protests, and statements as yet supplied to the Patent Office or to the technical press are unconvincing to an unprejudiced student of the subject. Even the Courts—or rather, therefore the Courts—in this and other countries have given decisions so contradictory as to warrant the conclusion that even the legal mind flounders amid the obscure phenomena and the obscurer verbiage of the patentees and their patrons.

Meetings and Discussions

The recent conventions in San Francisco, more particularly the Engineering Congress, have afforded many examples of the failure to elicit oral discussion on technical subjects. The failure, naturally, has not been uniform; in a few cases the conditions have been favorable; this was the case when the session was started by a writer that not only knew his subject and was able to make a clearly written presentation of it, but also had the gift of lucid speech, he being followed by several others likewise well equipped to conduct an interesting debate, under the guidance of an experienced chairman. But such a happy combination was rare. On average, not more than one out of these three desirable conditions was present. On the whole the discussions ranged from a mild success to a complete fiasco. We refer only to the mining and metallurgical sections; how the others may have fared, we do not know. The various factors that militated against success were:

1. An inexperienced chairman.
2. Absence of the authors of papers.
3. Absence of those most competent to discuss them.
4. Oral presentation of an abstract that was either scrappy or a mere repetition of the paper itself.
5. Unwillingness of those present to start a discussion or to take part in it when started.
6. Lack of time to ventilate the subject to any useful purpose when willingness did exist.

As regards the first condition, a chairman ought to control a meeting to the extent of checking aimless talking or persistent verbosity, which wastes the small amount of time actually available. He ought to aid the purpose in hand by recognizing those in the audience that are qualified to speak on the subject, and, if they do not come forward, invite them to do so, in case the discussion threatens to collapse. If an author is absent, it is well to pass his paper, for the attempt then to initiate a discussion is unlikely to be successful; it will have an air of unreality, because one hesitates to criticize opinions when their sponsor is not there to protect them or to make comments to which no reply is forthcoming. That may not always hold good, but it is true sufficiently often to justify a preference for the paper of the man who is present and able to respond on the spot. At the recent Congress, the young men designated as secretaries were told to read selected passages of pamphlets written by absent authors, but as these young men knew little about the subject their reading of scraps failed to summarize the printed matter; it only wasted time. A real abstract or précis of a technical essay requires uncommon skill. Not many authors are able to summarize their own writings off-hand. But the worst case was that of the man who read the whole of his paper, word for word, from a typewritten copy while the audience turned over the pages of the printed copies in their hands. He read it badly, so that if an interval of silence had been set aside those present could have read the paper more comfortably and in less time than the 30 minutes consumed in a gabbled reading of it. Moreover, the paper was not one that lent itself to discussion, and did not elicit any. The chairman did not stop the stupid performance, so that a large part of the session was wasted. At many of the meetings anything from six to eight papers of wide scope were set down to be discussed during two hours. The result was that the author or speaker who had any regard for others coming after him was prone to speak briefly or not at all, while one or two possessed of gab or effrontery could waste a whole morning. The idea of discussing half-a-dozen controversial subjects in a couple of hours is absurd. To present essays, reviews, or compilations of a non-debatable character for discussion is futile; they can be read more comfortably at one's leisure. So much for destructive criticism, now for constructive suggestions, in which we shall be glad to have the help of our readers:

If papers have been printed and circulated previous to the meeting, they should not be read nor even presented in abstract. The time should be devoted wholly to discussion. Those who have not read a paper are not in a position to discuss it intelligently; hence members intending to attend a meeting should take the trouble to read any paper to the discussion of which they expect to contribute or to listen profitably. That would save much time and much aimless comment. Next, the chairman, or the secretary, should see to it that two or three of the leading exponents of the subject are invited or urged to take part in the discussion, so as to give it form and direction. When the discussion has proceeded far enough, in the opinion of the chairman, he should call upon the author to reply. That would be his first participation, except for incidental corrections or answers to questions. Usually only one lively subject can be discussed in two hours. It is much better to discuss one subject effectively than touch upon a dozen ineffectively. There are subjects that are non-controversial, such as statistical information, useful compilations of facts, reviews of progress, and the like; these are suitable for thoughtful writing but not for lively debate; others are essentially controversial, they relate to processes and methods in course of development or pertain to current ideas of timely interest—these are the subjects to be selected, but not without regard to the probability of securing the attendance of those competent to speak on them in a useful and informing manner. We venture to go further, and say that the best kind of technical discussion is likely to ensue when an acknowledged authority, preferably a veteran, gives a short résumé of the existing state of knowledge on a given technical subject, points to the lines of recent development, acknowledges the difficulties it is most urgent to overcome, and, out of the richness of his experience, suggests one or two directions of possible advance. He can say enough to present the chief phases of the subject and in such a way as to invite others to contribute from their stock of experience. A veteran can afford to confess the deficiencies of his knowledge and also to hazard a guess as to the trend of future inventiveness. It is the young and relatively in-

experienced man that attempts an exhaustive review which leaves him and his hearers likewise exhausted. The average essay that is fired at the head of an audience does not invite discussion, it smothers—like Othello's pillow. One or two such experiences, if not fatal, will lead to an abstention from these public meetings and the foregathering of small groups of wiser and sadder men in the antechamber of the lecture-room, in the hotel lobby, or at the club, where they can exchange experiences and ventilate opinions without being bored by the bad reading of printed papers or the jumbled scraps of relentless technology fired at a helpless audience with the rapidity of a machine-gun. The ideal discussion is between three who know their subject; up to a dozen the number is still favorable if the speaking is orderly; but if a large audience is not to waste its time, it is imperative that the proceedings be organized properly. In order to do so, it will be well for members of the profession, more particularly those responsible for the arrangements at public meetings, to give serious thought to the subject and arrive at some system whereby the maximum of benefit may result. As conducted at present, these meetings afford a striking lack of the efficiency that is the ideal of the engineer. They recall the answer given by Talleyrand when, after a long diplomatic conference, he was asked what had transpired. He replied : "Two hours."

Prospectors, Engineers, and Amateurs

Our article on 'The Amateur Miner,' who wanted to get into mining and did not know how, has elicited some interesting discussion. In this issue we publish a good straight letter from one who represents the old-time prospector. For the purpose of argument, it may be granted that we stand somewhere between him and the amateur. In the main, we represent the engineer, that is, the man who applies modern science to the ancient art of mining. However, we have broken bread with the prospector: we have shared his blankets; to us he is a man and a brother. We like to hear from him, and we listen to him with understanding sympathy. Therefore we appreciate Mr. Richardson's protest against the engineer who tries to value a mine with a slide-rule and a tape-line. Have we not protested against the attempt to appraise mines on an investment basis? Mining is fundamentally speculative, and risk is the essence of it. Imagination is needed, and courage. Also some sort of instinct, based partly on inherited qualities, partly on experience, partly on keen powers of observation. That might seem too flattering to Johnny Cone or Pap Brenegan, but it is the complex of aptitudes that made them great seekers and finders of mines, as related by their friend, Mr. Richardson. He says they wandered over the hills "looking *for*, not *forninst*, mines." Presumably the gentleman with the slide-rule represented the *forninst* idea. Probably he did. Mines are not discovered by formula, any more than great men are bred from ordinary babies by an elaboration of scientific nourishment. The tendency to put money into developed mines, thinking thereby to diminish adverse chances, has tended to check the adventurous effort on which mining is nourished. We like the man who would "turn down the Little Tinker cold" on an examination for a client but would be willing to risk his own money on the same prospect. Perhaps that is what is the matter: the decrease in the number of those willing to put their own money into small ventures—the small ventures out of which big enterprises grow. We hear less of the individual operator, like George Hearst, Alvinza Hayward, James B. Haggin, Patsy Clark, Moffat, Delamar, and the like, most of whom made their money out of the ground itself, and not by promoting companies or playing what is called the mining game, that is, selling 10-cent shares to a gullible public. Such 'adventurers,' using the word in its old Elizabethan meaning, have become rare because, among other reasons, the chances for them have diminished. The face of the earth, even the far recesses of the high ranges and the upper limits of the inaccessible creeks, has been surveyed by the topographer and mapped by the geologist. To find virgin territory the explorer must travel north-westward or else choose those tracts over which search has been made for only one or two out of the many metals valuable to man. To succeed he must have not the sophisticated mind of the modern expert, who knows only how to estimate the ore that has been proved, but the optimism that never grows old, mounting to an invincible assurance that the find is not far ahead. That spirit was typified by the old prospector and his burro, by the store-keeper that grubstaked him, and by the assayer that tested his samples as against payment when the lucky strike was made. Yes; we miss that phase of mining; perhaps because we live so much in cities. But somewhere in the hills, in the frontier settlements, the old scenes are still repeated, and the inexpugnable hopefulness of the mineral explorer is in play as in days gone-by. Pap Brenegan's burro is coming down the road laden with a couple of sacks in which is the first fruit of a Chrysolite, a Homestake, or a Treadwell. Reality stifles imagination. We hear so much about the colossal enterprises that we forget how they grew from a fortuitous prospect-hole up the creek and a simple digger in overalls. The adventurous spirit is vanishing like the mist of morning on the high mountains. The unknown retreats, the foreground enlarges. Where once the lone prospector tramped, the long train of gondola-cars laden with ore winds its confident course along the steel highway. The prospector must step aside and take the lonesome trail beyond the reach of the thunderous engines of progress or the whispering wires of civilization. Yet, he ought to be cherished by those controlling the mining industry, not out of sentiment merely but as an essential to the healthy expansion of organized effort. When the millionaires made by mining have finished building libraries, endowing colleges, and running newspapers they might well consider the idea of setting aside a fund for the regular grubstaking of a selected number of real prospectors, the proceeds of their discoveries to go, in part, at least, to the pensioning of worn-out workers in mine and mill.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Amateur Miner

The Editor:

Sir—The editorial in your issue of July 24 flags me with a question. You refer therein, as you consistently and insistently do, to the function of the mining engineer as the court of last resort and also first resort on things mining.

I have no quarrel with the mining engineer. But I sometimes wonder if he does not think too much in terms of caution, suspicion, feet, and tons. Become too much *Quod erat demonstrandum*, with the starting promise "It is a risky chance" as it were. Does the attitude not become subconsciously ingrained, like the man who started out to hunt the fellow who ran away with his wife and hoped, by the Great Harry, he wouldn't find him.

Going down on the boat last winter a number of us got to speaking of this phase and among us was a man who might have been your 'Amateur Miner.' He listened to us talk shop and josh about this property and that, which some of us had had the job of inspecting, and finally he said, in effect: "Seriously, I want to ask a question. I know nothing of mining. I have been up to look into some mining business that has happened to come into my hands through the death of the principal owner and my connection with his heirs. The estate is a large one and this matter is comparatively small. Money could be spared to do some work on the property even if it was likely to be lost. I have met the men who are interested in the property, and I have seen the property. My feeling has been that I would advise going ahead. Understand, I do not know anything about a mine, and I have not attempted an examination of the property, though I have been familiar with the developments in connection with it in a business and mining way for upward of two years. I have read assays and descriptions of the working conditions, which seem to be borne out in what I have seen. But the conversation that I have listened to for the last two days, and what seems to be the somewhat cynical attitude of you gentlemen, some of whom at least I take to be mining engineers, has about convinced me that I had better keep to other matters with which I am more familiar. However I want to go a bit further before I drop it. Will you give me the name of a competent engineer to examine this property, whose report and judgment I can rely on. I know men familiar with coal and iron and oil properties. But somehow these Western conditions seem different. Now will you name me a competent engineer?" All the rest but Johnny Casey, Frank Haynes, and myself modestly declined to say "Me!" We three weren't engineers. I presume each one of the crowd thought of some of the other men in the bunch, for there were five or six in the corner of the smoke-room who were competent to pass on a prospect, at least.

Somebody asked "What kind of a property is it and where is it?"

He told us, and a half-dozen names were suggested. Two or three at once gave the name of an engineer who was then in the locality.

A man, engineer and operator, well known to the editors of the PRESS and the oldest in the crowd, said quietly: "I pass. I would not recommend him to examine this property, and some of you know I am an intimate friend of his."

"Why?" came from several of us.

The engineer mentioned, Mr. Blank, was experienced, with a fine technical education and an unusually superior mind, he was keen, honest beyond cavil, and careful to a degree.

"Well, I'll tell you" he said. "One night in the Silver Bow Club we were discussing him and Smith said: "The trouble with Blank is he is inconsistent. He makes all these hard trips, gets skinned up and busted up, and freezes, sweats, and starves, when he might just as well turn down the properties in the office, with his feet cocked up on the desk before he starts. He don't need to go and see 'em. He made examinations for me for two years. He turned down everything he looked at including the ——— in ———, which I would have taken, the ——— and the ——— which would have made me half a million dollars. Give me a hundred thousand tons of ore blocked out, a complex geological situation, a working plant to be figured out and installed, and I know of no superior to him. But he can't see a mine until it is built, so that you can put a slide-rule and a tape-line on it. He lacks imagination. Now Mr. Dash wants to know "Have I possibly got a mine in this property?" And you boys that know him know that Blank will tell him he has *not*. We fellows *here*, can just as well tell him so, as to have him go to the expense of having Blank examine and report on it."

It was pretty drastic. But, knowing the man, I think it was true.

And isn't it more or less your own and my case? I confess I have got it. I start to look at a property and I begin to see possible obstacles and difficulties. I question what the owner is concealing from me, where the nigger in the woodpile is. The hill don't lay according

to my preconceived notions, and the ore occurs differently. They left too many knots on the poles under the bed and the bacon is rancid and I can make better bannacks than those myself, and I can make pretty poor ones when I try, and I wouldn't come down over that bluff in the sleet again for a milliard dollars. And I don't think it is the kind of a property that my client wants anyhow, and I have protected him from a possible bad investment, and my conscience is clear. And were my client to see it, he would probably agree with me.

And then my mind runs back to 'Old Man' Aldrich, Johnny Cone, Otto Abeling, Pap Brenegan—I can see him now with his fat tummy sticking out over the place where the saddle-horn, which he had knocked off with an axe, should have been—Bill Springer on a saddle-horse leading his pack-pony, Jim O'Brien and others, trailing around through the hills looking *for,* not *forninst,* mines. Their work, at least some of them, may have lacked the precision of thought and expression demanded now, and they would have turned a modern flow-sheet upside-down perhaps, to see what the picture was all about. But among them they found properties that eventually made mines. Some big and some small, but which warranted the confidence placed in them by their backers and made and lost them money.

I had occasion the other day to turn in what I like to call "a report." There were more pages of it than there are of this—which is too many. In the accompanying letter I said "For *your* purposes—referring to the characteristics of the addressee—I would make this in about nine lines." Perhaps *you* remember the Gashweiler report. [We do.—Editor.]

Now the kernel in this nut, if there be one, as it refers to the 'Amateur Miner' not wanting to become a minority stockholder in a large company, but wanting to *mine,* is this. In the trend of conditions toward big things, as specially exemplified in a mining way by such properties as Utah Copper, Chuquicamata, Interstate-Callahan, Alaska Gold, with their ability to install refinements of technical operation with resultant economies, are we not altogether losing sight of the opportunities for the sensible placing of money and endeavor in smaller properties, where they will make an adequate return and help to make prosperous little communities, as against big ones? Are we not minimizing the desirability of small undertakings? Are we not perhaps keeping 'Amateur Miner' and a lot of men of courage and enterprise, coupled with only small or moderate means, from mining? They get technicalized and engineered and processed into the Willies, with the idea that mining floats on some kind of a nimbus beyond the reach of common mortals.

The country where you see one and four and a dozen jacks poking down to the railroad once or twice a week or day, with a sack of ore on each side, or the country where an arrastra on the creek, perhaps evolves into a five-stamp mill, where they do pretty bad milling, and there is another one plugging away over the ridge, with fig-trees in the yard by the house, looks just as good to me as does the plant that speaks in terms of thousands of tons, and where, if you are a married man and get a job there you move the Missus and the kids into shack 46, between Ole Halvorsen and his good woman, in 47, and Maguire and Blondie Annie in 45.

Up the creek we've got the Little Tinker. Sometimes six inches, sometimes three feet of *real* ore. Would I ask P. D. & Co. or the A. C. M. Co., or the A. S. & R. to send an engineer to "examine" it? No. But where is Pap Brenegan—peace be—? To blow in out of nowhere and bound anywhere, to stay over-night with you and swap old lies. To go up in the morning and look it over. "Ye should sink from de ind av de drift, an' punch a hole in de hangin! Maybe tis *not* de wall. An' how do you say she runs? She do? Any ixciss of iron? What's your freight an' treatment rates? Goold an' silver values pretty rigular?"

You sit down on the dump and smoke and talk of various things and look at the blue haze gather over the hills across the canyon. "Say," says Pap "I know four or five fellys that have a lease on a block of ground in the Portland at Cripple Creek. Maybe dey would look at yer hole here. An' Mr. Amateur Miner from Bridgeport, Connecticut, I met him on the train goin' in to Salt Lake last fall. He says he has frinds that make brass and money, and he writes me that they will look at a small lay-out. Ye cannot till, maybe 'twill be like Moorphy's wife."

You made a deal. Some time later in boiled four roughnecks from Cripple Creek with steel and powder, tent and grub, and started to shoot the bottom out of the Little Tinker, and the bottom—may be—stayed in, and they are still looking for it. It has proved nothing big, but it has made livings, paid wages, helped develop other prospects, good, bad, and indifferent, and perhaps in the ultimate helped develop initiative, resource, and that dandy stuff—no thin sections have yet been made of it to determine its crystallization or what precedes the 'ite that puts it in the books—that makes the American mountain-man and miner.

Now! As an engineer, if I was one—which I wish I was—I would turn down the Little Tinker *cold* on an examination. But I will put my own precariously earned or stolen money in on it.

The theory? So near as I have it shaped: The engineer comes in properly as a mathematical and scientific factor. Tons, horse-power, formulae, and formations, instruments and 'sich,' a trained mind in a trained body, a follower, a locomotive on a straight track reaching the same place by so much shorter distance and so much less time than the old game-trails did. But there are adventurous summits, and bald descents that he has no place on.

As for Mr. Amateur Miner discussing with one or two engineers of his own social stratum, how would it have been if he had jolted his mental processes by talking to Pap Brenegan, Old Man Aldrich, or Jim O'Brien, men who were looking for prospects and didn't care a tinker if they found one?

Current mining mythology says, especially among the old-timers, "Why, George Hearst could tell a mine as far as he could see it." And I can believe that too. And he could probably tell it *no farther* than he could see it. My recollection of mining fables says he "saw the Homestake." He may have added to keen judgment, a vivid imagination. Taking into account the time, 1877, if I recall properly, and the conditions, not only surrounding the Hills, but the metallurgical and milling knowledge of that day, if it *was* McMasters that recommended its purchase, he must have had a colossal nerve. I wouldn't do it today. Would you? Recalling the conditions? Some 300 miles of Indian country before you reached the tender mercies of the U. P., as I remember the distance.

We want more Hearsts or McMasters, and then not so big. As I have quoted before, Pap Brenegans and gentle Ludwig Sollweins, who would turn a fire-weed out of his road before he stepped on it, and who perhaps did not tell you all he knew about the rarer metals. And pirates like Step-and-a-half Flynn, and Bill Ginschman. The making of the little man and the little property.

Show me from forty to a hundred sore-backed pack-horses a day, and a few ore-wagons, passing my cabin, and I'll show you more human happiness than comes from "breaking her 400 ft. wide," or running a dozen steam-shovels on her. Let the packs keep on traveling and ultimately will come the time that we need the cool judgment, the technical knowledge, and the accuracy of the engineer, to find out whether we have mines or merely prospects.

In the meantime we want the Brenegans, the Flynns, the Amateur Miner—if he hasn't too much money—and perhaps even the MINING PRESS, not forgetting Halloran.

By the way, if any of you know of Ludwig Sollwein's whereabouts, let me know. I have not heard of him for years. CHARLES P. RICHARDSON.

Kitselas, B. C., August 28.

[We refer to this interesting letter in our editorial columns. Of course, we are pleased that Mr. Richardson and his comrades should still want the PRESS and we join with him in "not forgetting Halloran." We are glad to add that, having seen Mr. Joseph F. Halloran recently, we can vouch for his excellent health.—EDITOR.]

Corrections

The Editor:

Sir—Under the head of 'Concentrates' and as space-fillers in odd corners of your magazine a lot of useful matter is to be found, but in collecting matter of this kind errors will, at times, creep in. In your issue of September 4, I find: "Smoke combustion and smoke-burning are not considered good terms in the discussion of furnace-firing. When once made, lamp-black is incombustible and cannot be burned." Anyone who has seen a chimney through which the products of soft-coal combustion escape on fire, or, more correctly, the products of incomplete combustion on fire, will agree that not only is lamp-black combustible but it is capable of producing an intense fire.

Again, as a filler in your issue of September 11, I find: "Combustion may be defined as the chemical union of combustible matter with oxygen, the supporter of combustion." In the early days of chemistry, chemists divided gases into combustible, supporters of combustion, and incombustible or inert; but they have long since given up this classification because the terms are only relative. When, for instance, coal-gas burns in air, as we are apt to say, the oxygen of the air burns and is just as much a part of the combustion as the coal gas. A pretty experiment illustrative of this can be arranged by taking an ordinary lamp-chimney, fitting a cork with two holes, through which glass tubes pass, in the bottom of the chimney, connecting one of the tubes with the coal-gas supply, and leaving the other one open. A piece of fine-mesh copper screening should be placed on the top of the chimney, and the hand placed over this until the chimney is full of gas, then, when the gas begins to flow out of the open tube, it is lighted, the hand removed, and the flame will fly back into the chimney. The surplus gas can be lighted above the copper screen on the top of the chimney, and we have the phenomenon of the oxygen of the air burning in an atmosphere of coal-gas within the chimney and coal-gas burning in air on the top of the chimney. In like manner hydrogen can be made to burn in an atmosphere of chlorine or chlorine in an atmosphere of hydrogen, and so with other gases, so the terms combustible and supporter of combustion as applied to gases being interchangeable should be allowed to die a natural death.

I know the PRESS always welcomes criticism, and, if it does not agree with the critic, is willing to enter into a friendly argument on the subject. I take it, too, that, though you are glad to have errors pointed out on the few occasions that they appear in your magazine, you are sufficiently human to appreciate praise when you know it is sincere, so I venture to congratulate you on the great improvement in the PRESS since you returned to the helm. As it appears today, it is a wonderfully readable magazine, and it is a subtle compliment that a good deal of the matter between the covers is read by the wives of many of the engineers as well as by the engineers themselves.

F. H. MASON.

P. P. I. E., San Francisco, September 20.

CLAY PRODUCTS of the United States in 1914 were valued at $164,986,983, brick and tile being worth $129,588,822, and pottery, $35,398,161. The total was considerably below that of 1913.

ELEVATING PULP at the Tonopah-Belmont mill costs $0.00165 per ton by a 20-in. bucket-elevator, and $0.00175 per ton by a 4-in. solid-lined pump.

IRON ORE shipped down the Great Lakes in August amounted to 8,081,177 tons, against 5,869,477 tons in that month of 1914.

Soroche and Verrugas

A query from a young engineer who was negotiating with regard to a position in Peru and his evident ignorance of the nature and dangers of mountain-sickness, or *soroche*, leads us to think that many other engineers may welcome information on an important, but little discussed, subject. Although our inquirer did not ask about *verrugas*, we mention this disease because it exists along the line of the railway from Valparaiso to Oroya, in Peru in the same region where we first fell a victim to soroche.

Soroche is characterized by headache, nausea, and vomiting, thus resembling sea-sickness; bleeding at the nose is also common; like sea-sickness it does not affect all persons. The cause of it is said to be lack of oxygen in the rarefied air of high altitudes; another theory is that the diminished pressure allows the gases of the body to expand, thus disturbing the relation of the internal organs. The symptoms of the disease are well shown in the following description of an experience on the Valparaiso-Oroya railway:

"The sun shone brightly and the Peruvian passengers were laughing and joking. After reaching an altitude of about 12,000 ft., laughter ceased; with the increasing altitude faces grew paler; by the time we reached 14,000 ft. several passengers, fully overcome by soroche, were vomiting. Near the summit, I left the main line going off on a branch line, whose highest point is practically the same height as Mont Blanc (15,782 ft.), to Yanamina. I had not been ill on the train, but felt depressed when I went to bed; my night was troubled by confused dreams and nausea, finally relieved by vomiting. On the whole, I felt as if I had been sea-sick."

Some travelers do not suffer at all from soroche; others have much more violent attacks than those described above. In rare cases death results. As a rule the sufferer becomes acclimatized within a week or two. But with a change in the weather the disease may return. We heard a Peruvian landlady who had lived at an altitude of 14,500 feet for twenty years say that she still suffered from soroche whenever the weather was unfavorable. Persons who have lived at a high altitude for a long time become ill when they descend to low altitude—a sort of reversed soroche. This malady, caused by the change from a higher to a lower level bears out the theory that the disease is caused by a displacement of the viscera due to a change of pressure. Soroche does not depend on altitude alone for it is certainly much worse at the same altitude on the railway from Valparaiso to Oroya than it is on the railway from Mollendo to Puno. Thus there is a certain mystery about the disease.

But a more mysterious and much more dangerous disease is *verrugas;* this occurs on the same Valparaiso-Oroya railway. It does not exist at Lima, practically sea-level, or at Matucani, 8000 ft., but is found between those places at an altitude of, say, 3000 ft. Verrugas starts with a high fever, followed within a few days by a copious crop of brown warts that may be an inch or more long; death results in the majority of cases. It is said that 75% of a gang of American bridge-builders, engaged in the construction of a viaduct on this railway, died from its effects. The disease attacks a large proportion of all persons who remain in the special locality for more than a few hours. Travelers passing through on the trains are not attacked, but trainmen who pass by daily may fall victims. Quail hunters who go from Lima for a day's shooting, taking their food and water from home, do not always escape the malady. A young doctor who went there for the purpose of studying the disease died before he could record his symptoms.

Our information in regard to verrugas was obtained during a visit to Peru in 1903. Since that date we have often examined medical literature, but have found nothing greatly at variance with the above statement. If any of our readers have later, or more authentic information, we shall gladly publish it. The suddenness of the attack combined with the virulence of this disease makes one think that the old stories relating to the Upas tree may have some other basis than the fact that its sap produces a cutaneous eruption.

Engineers who go to foreign countries will do well to act on the principle that the natives of the country, even though they may be uncivilized, know what is best—especially as regards living conditions and travel. The stranger should follow the customs of the country, unless he is sure that injury will result. This example illustrates the point: A young engineer starting his day's journey from 9000 ft. to ascend to a pass of 16,000 ft. was told that it was best not to eat anything before crossing the pass. But as he did not believe on traveling on an empty stomach, he disregarded the advice and ate a hearty breakfast and luncheon. On reaching the pass he was attacked by a violent colic, from which he suffered agonies. Many strange foreign ways have a sound foundation as had the custom of shutting one's self tightly in a tent at nightfall and not coming out until after daybreak. The reason given by the Peruvians was that the night air was poisonous and brought fevers. Now we explain the fevers by the malarial mosquito.

An engineer should remember that by far the most important duty is to take care of his own health. Health is his capital; moreover, when he loses his health his employers lose his hard-won experience. Hence, we say to engineers: Health first as well as Safety first.

The lode in the Edna May mine, in the Southern Cross district of Western Australia, is a gold-bearing quartz in granite, lying east and west. It is a 'freak vein' as far as that State is concerned, and at variance with the experience of the local mining men. The output totals $1,250,000 from 60,000 tons.

Coal production of the United States in 1914 (final figures) totaled 81,090,631 tons of anthracite valued at $188,181,399, and 422,703,970 tons of bituminous coal and lignite worth $493,309,244, a total decrease of 56,434,742 tons.

The Economics of the Metallurgy of Zinc

By WALTER RENTON INGALLS

*Even before the war began, the zinc industry of the world was experiencing radical changes. The effect of the war will be to produce more changes, whereof no man can yet clearly foresee the nature and scope. Looking backward, we can now perceive that 1896, when the Wilfley table was introduced, was an historic date in the metallurgy of zinc. Making possible an improved concentration of mixed ores requiring fine grinding, the first step in the solution of the long-baffling mixed ore problem had been taken and the smelters were offered a new and bountiful supply of lead-bearing zinc ore, often high in iron, to which they had to adjust their metallurgy. Another important step in the separation of mixed ores occurred subsequently with the introduction of Wetherill's system of magnetic separation and Blake's system of electrostatic separation, but the climax occurred with the successful introduction of the flotation process at Broken Hill.

The development at Broken Hill had at least three great consequences, namely, it standardized smelting practice in Belgium and Germany; it compelled nearly all of the smelters of those countries to go on a zinc-lead basis; it showed that mixed ores could be profitably treated, and caused a search for them to be made in all parts of the world, which within a few years resulted in the development of such mines as the Butte & Superior, of Butte, Montana, the Bawdwin, of Burma, and the Ridder, of Siberia, to mention only three of the first order.

Let me be more explicit respecting the above statements. The total zinc production of the world, in 1913, was about 1,000,000 metric tons, of which Belgium, Holland and Germany produced about 500,000 tons. Broken Hill, in 1910-'12, produced an average of 450,000 tons of blende concentrate per annum, averaging 46 to 47% zinc, which may be roughly calculated as equivalent to a yield of 170,000 tons of spelter, or about 35% of Germany and the Low Countries.

The immense Australian ore-supply was contracted to the three great German metal-merchandizing firms, which distributed the ore among the smelters of Germany and Belgium. Those smelters coming thus into possession of so large, so uniform, and so regular a supply of ore, the like of which in none of those respects had ever previously been experienced in the zinc industry, were able to standardize their smelting practice, not only as to a single works but also as to many works; which was metallurgically beneficial.

The Broken Hill zinc ore was rather high in metal. In previous times, zinc smelters generally were averse to smelting ore containing more than 2 or 3% lead, although there were a few smelters who made a practice of treating ores relatively high in lead and recovering a considerable proportion of the lead therefrom. With the advent of the Broken Hill ore, the recovery of lead as a by-product in zinc smelting became the regular thing; and in fact, the smelters of Belgium and Germany went practically upon a zinc-lead basis and even became insistent upon having a percentage of lead present in their ore, that was far above what in earlier years had been regarded as permissible.

Another radical change in the zinc industry, that was in progress previous to the war, involved the establishment of new *loci* of zinc smelting and was rather directly connected with the Australian development. The art of zinc smelting is one of a multiplicity of details in which the part played by many workmen spells the difference between success and failure. No matter how careful the plans of the engineer may be, they are likely to come to naught unless there be good workmen to carry them out; and the making of good workmen requires long training. The possession of a class of workmen which has been engaged in zinc smelting during several generations, is one reason why Belgium continued to be a great zinc-smelting country long after its own resources were exhausted. And because of the absence of such a class of smelters, it has been universally the experience that the inauguration of new zinc-smelting enterprises in new regions has been attended by difficulties which generally have wrecked the adventurer. With the advent of the great Australian ore-producing interest, however, there entered into the zinc industry a group of concerns with financial resources that enabled them to build zinc-smelting works in any logical location, and, with equanimity, to carry them through the period in which the native population had to be taught how to smelt zinc ore. Thus, we have already witnessed the erection and operation of two zinc smelteries in Australia; we have seen the foundations laid for a great zinc smeltery far away in Siberia; and we have reason to believe that ere long a zinc smeltery may be erected at some seaport of India. In the meanwhile, the Japanese, with their customary adaptiveness, have inaugurated zinc smelting within their empire. There were, therefore, plans on foot that promised to make the art of zinc smelting one of far wider application than it had ever been during the century of its commercial history. These conditions were fully in evidence before the War began.

Germany, by virtue of its own great deposits of zinc ore in Upper Silesia and its contracts for the Broken

*A paper presented before the International Engineering Congress, 1915, in San Francisco.

Hill ore, was the great purveyor of spelter to the rest of Europe, especially to England. The first great consequences of the war were to suspend, to a major extent, the production of zinc ore in Australia, there being insufficient surplus smelting capacity outside of Germany and Belgium to receive it; and to throw a large part of the spelter requirements of Great Britain, France and Russia upon the United States, the result of which was to raise the price of spelter to a figure not previously recorded in many years. What other major and minor effects the disturbance of the war may have upon the spelter industry lie within the sphere of prophecy. I will venture no more than the suggestion that they will be profound.

The world's great districts of zinc smelting have heretofore been Upper Silesia and Rheinland-Westphalia, in Germany; the valley of the Meuse and the Campine, in Belgium and Holland; Kansas, Oklahoma, and Illinois, in the United States. The art of zinc smelting was first introduced (from China) into Great Britain, but the British smelters have not, during the last 100 years, been leaders in the art; nor has zinc smelting attained great magnitude in their land.

During the last 50 years, there have been three types of zinc smelting (the earlier English and Carinthian processes having disappeared), which are known as the Silesian, Belgo-Silesian, and Belgian. In recent years, the Belgo-Silesian method has become known as the Rhenish, and this has shown a strong tendency to displace the Belgian process in Belgium and an even stronger tendency to displace the Silesian process in Silesia. The reasons for this are discussed in the metallurgical treatises, of which zinc smelting has recently acquired a rich literature. They may be summarized as a superior economy, as compared with the Belgian furnace; and, in Silesia, a change in the character of the ore which causes this method to be better adapted than the Silesian furnace. In the United States, the method of smelting is essentially the Belgian, which has been modified to conform to peculiar conditions.

Considering the art of zinc smelting upon its broadest lines, the variations between European and American practice are explained by variations in fundamental conditions, which may be summarized in the statement that in Europe labor is cheap and coal is dear; while in the United States, coal is cheap and labor dear. Thus, we find American smelters striving ever for mechanical substitutes for hand labor, and European smelters aiming always to reduce coal consumption. There have been other determinative factors, the differences between which are, however, tending to disappear. One of these is permanence of the smelting districts. Another is scientific attention to the art.

Zinc smelting was begun in Upper Silesia in 1798 and on the Meuse in 1807, and ever since those dates, has been conducted in those districts. Their metallurgical stability has induced operators to build substantially. From an early date, moreover, the smelting was directed by educated metallurgists, and both in French and German is there a literature extending backward for a century. In the United States, on the other hand, only two works, namely, those at LaSalle and Peru, in Illinois, have a long history, and, in the main, the zinc smelting industry has been characterized by shifts and uncertainties that stifled ideas of permanent building. About 1871, zinc smelting was begun at Pittsburg, Kan., and for 30 years was conducted with an absurd disregard of scientific control. Not until about 1898 were chemists employed, even to assay the ores bought and smelted. Ore was cheap, and for three decades the precept was "better butcher the ore than butcher the furnace." About 1901, most of the smelteries in this district were scrapped and the Iola district, where natural gas occurred, became paramount. Ten years later, Iola was the scene of deserted works and the star of Bartlesville and Collinsville, in Oklahoma, was ascendant, but even now it is waning and the great locus of zinc smelting is becoming the coalfields of Illinois and farther eastward. With this last move, zinc smelters show that they are building for permanent business, not merely to reap some ephemeral natural advantage, and with the utilization of the services of metallurgists (which has been general only within the last 10 or 15 years), certain differences between European and American results are tending to disappear.

One other basic condition requires mention. European smelters operate generally in highly developed industrial regions, affording a market for sulphuric acid and rendering the free discharge of sulphur smoke unpermissible anyhow. Therefore, European smelters long ago began to make sulphuric acid as a by-product of blende roasting. American smelters, on the other hand, were able to emit their smoke without doing great harm and had no market for acid. Consequently, they did not make it. This condition, also, is undergoing radical change. Every smelter of blende east of the Mississippi river now makes acid.

In many respects, the development of the American zinc smelting industry has exhibited absence of initiative and curious contradictions. Our two great names are Wetherill and Hegeler. The former invented the process of making zinc oxide direct from ore. The latter introduced the first successful mechanically-raked muffle furnace for roasting blende, modified the Belgian distillation-furnace and introduced many mechanical contrivances. The best American zinc-smelting practice of the present day follows very closely in Hegeler's footsteps, with certain improvements borrowed from Belgium and Germany.

During the last 20 years, the vogue of the mechanical furnace for blende-roasting, in the United States, has become all but universal. At the present time our works have capacity for roasting about 800,000 tons of blende per annum, and only two or three examples of the old hand-roasting kilns survive. Yet, of our mechanical furnaces, the Hegeler dates back to 1884, and during the last 15 years there has been no introduction of any new type—an emphatic commentary upon the absence of

originality that has, heretofore, characterized zinc smelting in America. In the meanwhile, the Germans have exhibited much alertness in developing and adopting mechanical roasting furnaces in spite of their lower rates of wages and consequent lack of incentive to substitute machines for men.

I may best elucidate further comparisons between European and American practice by sketching the principal parts of a modern zinc-smelting works. In all of what follows in this paper, I have in mind only the smelting with coal-fired furnaces, dismissing from attention the smelting with natural gas in the United States, which is on the wane. Nor are the figures that I give intended to represent the practice with Silesian furnaces in Upper Silesia, Germany.

The ore is delivered into the works in railway cars, from which it is unloaded directly into the storage-bins. The means for unloading, sampling, storing, and reclaiming have, heretofore, been rather crude in many of the American works, but recently there has been an increasing tendency to adopt the superior methods that have long obtained among lead and copper smelters.

The ores coming to the zinc smelter are classified as calamine and blende. In Europe, the former is still calcined. In America, the calcination of calamine was abandoned by the smelters many years ago, the advantages being pronounced unequal to the cost. Blende, of course, must always be roasted. In America, we use the Hegeler furnace if sulphuric acid is to be made; otherwise, simpler forms, of mechanical furnace. Our object is mainly to save labor. In Europe, hand-raked furnaces of the Rhenania, or the later Delplace, type are commonly employed, which are both designed and operated to save coal. The dead-roasting of blende has been regularly effected with a coal consumption of only 10% of the weight of the ore, a lower figure than has ever been achieved in the United States. However, there is a growing usage of mechanical roasting furnaces in Europe and an adoption of such new and excellent types as the Merton and the Spirlet, which American smelters have not yet ventured to try.

The roasted ore goes to the mixer, where it is united with the proper proportion of reduction coal. Mechanical mixing and careful attention to this important part of the process were early practised at LaSalle, but, elsewhere in the United States, this was generally done in ways far below European standards until recently. However, we are no longer subject to such a reproach.

Following European practice, our distillation furnaces are now commonly built entirely above the ground, the unclean, uncomfortable and unsanitary subterranean galleries of old being abolished. The Europeans are still ahead of us, however, in ventilation of the furnace houses. The Europeans generally lay out their furnaces in line. We lay them out in rows. The Europeans commonly employ recuperative (both reversing and countercurrent) furnaces—again with view to economy of coal—and succeed in smelting a ton of ore with as little as a ton of coal. In the United States, we use mostly the long Hegeler furnace. With natural gas firing, there is no heat recuperation. With coal firing, the economizing of fuel takes the form of generating steam from the waste gases. The long furnaces and the steam boiler accessories are distinctly American, and both are due to Hegeler. To Hegeler also is due the charging car, metal drawing car, and other mechanical contrivances in aid of the work about the distillation furnaces. The only successful mechanical chargers, however, are of European origin; but a recent American invention of some promise is a mechanical discharger. A distinctive feature of American distillation furnace practice is the use of blowers for the delivery of the combustion-air to the furnaces.

In the manufacture of retorts, the hydraulic press, which originated in Belgium, is now commonly employed both in Europe and America. However, the Europeans give more attention to the manufacture of their retorts and, unquestionably, make a better retort than we do.

In the handling of material in the works, the modern American plants are as well equipped with tramways, elevators, etc., as are lead smelteries of corresponding size. In this respect, our best American plants are in no wise inferior to the best European.

European smelters have long recovered lead and silver from their retort residues. American smelters now do so to a considerable extent, but the treatment of lead-bearing ores and recovery of the lead is less a feature of American practice than it is of the European. American zinc smelters pass the whole of their residue to the lead smelters. European zinc smelters concentrate it by jigs and tables and deliver a lead concentrate for smelting.

Metallurgically, the essence of zinc smelting is the temperature of distillation. Speaking generally, the higher the temperature the better is the extraction of zinc. But with bad ores, and bad practice, high temperature is indefeasible; for the furnaces and retorts will not stand it. A bad ore may be smelted with but little trouble, at a relatively low temperature, but the extraction of zinc will be poor. The aim of the zinc smelter is to melt a bad ore and obtain the maximum possible percentage of zinc out of it.

In general, the Europeans excel the Americans in this respect. They mix their ores scientifically, they make better retorts and they build stronger furnaces, all of which contribute to an ability to drive their furnaces at higher temperature than Americans have yet attained, and, at the same time, they manage with ores that are rather high in lead. In so smelting, they make a leady spelter, but a simple refining in a reverberatory furnace removes the excess lead. In only one American works is that practised.

European smelters also generally recover 'blue powder' as a commercial product. This is obtained from the 'prolongs,' which condense a proportion of zinc that would otherwise be lost. American smelters do not use prolongs. Although in trials of them, an additional 1 or 2% of the zinc has been obtained, they have found it to be unprofitable—this again reflecting the difference in labor conditions.

I have outlined the main differences between European and American practice in zinc smelting. They are explained by the reasons previously mentioned. Per ton of raw sulphide ore, the American smelter uses about 2 to 2½ tons of coal and two or three man-days of labor; and extracts about 84 to 88% of the zinc that is in his ore; if he treats lead-bearing ore, he may recover 50 to 60% of the lead.

The European smelter uses about 1¼ to 1¾ tons of coal and 3 to 3½ man-days of labor; and extracts 88 to 90% of the zinc that is in his ore, and about 50 to 70% of the lead.

I hope to disarm criticism of these figures by stating that such figures properly should be accompanied by qualifications and explanations that would run to pages in length and would constitute a condensed treatise upon the metallurgy of zinc; and that I offer the figures that I have used merely as broad generalizations for the purpose of exhibiting, in tabloid form, the lessons deduced from the differences in the art as practised in Germany and the Low Countries and in the United States. They mean that the Europeans, with the aid of better furnaces and superior technical direction, are able to smelt more refractory ore than we Americans, and yet extract a higher proportion of the valuable metals. They have built more substantial plants—secure from fear of geographical migration of their industry—for the sake of increased durability and maximum economy of fuel. While the rates of wages are higher in the United States than in Europe, American zinc smelters have not been able to offset that by the development of superior efficiency, in the ways that the copper and lead smelters have done. Man for man, the German and Belgian smelter does as much work as the American. Thus, the attendance of the distillation furnaces in Rheinland and Belgium requires 1.75 to 2.5 man-shifts per ton of roasted ore, while in America the requirement is 1.75 to 2.25. The difference in labor in roasting is insignificant when mechanical furnaces are employed. Such economies in labor as America has effected have been chiefly in the handling of material, which, in zinc smelting, is a relatively small part of the process.

Before concluding this paper, I am bound to refer to certain misconceptions respecting the status of zinc smelting that continue to exist and the possibilities of any radical changes happening in this art, such as have happened in lead and copper smelting.

The art of zinc smelting is far from being at a standstill. When we find 1000 kg. of ore requiring 1000 calories of heat being distilled with 1100 kg. of coal equivalent to 8000 calories, as is done in the best practice, we are observing a thermal efficiency of 12½%, which compares favorably with good steam practice. When we find a ton of ore being smelted with 2½ man-days of labor, and consider that we are dealing with a concentrated product, and reflect that the total weight of material handled is relatively small and that the work on it from step to step is often more cheaply done by a man than by a machine, we do not feel unduly mortified by our results. Nor does the extraction of only 85 or 90% of the zinc content of the ore shame us very much when we reflect upon the peculiar and troublesome metallurgical properties of zinc.

The so-called problem of the mixed sulphide ores that has engaged so much attention during 50 or 60 years, is not a question of how such ores may be treated—for means have been known for a long time—but, rather, is it a question of how may such ores be treated with sufficient cheapness. This problem has been solved to a large extent by the improvements in the art of mechanical concentration (especially the flotation process) and the improved ability of the zinc smelter to treat plumbiferous and ferruginous ore. Yet, there are still ores whereof the beneficiation is highly unsatisfactory, such, for example, as those ores which contain fluorite and those ores which are a crypto-crystalline mixture of the component sulphide minerals. The present treatment of zinc ores that are high in silver leaves much to be desired. For some of these ores it is possible that hydrometallurgical, or hydrometallurgical-electrometallurgical processes, may be useful in certain cases. There has been a commercial hydrometallurgy of zinc for many years, but it has not been extensive, simply for the reason that most ores could be more profitably treated in other ways. The precipitation of zinc from solutions by electrolysis used to be troublesome and unsatisfactory, but now that seems to have been mastered.

Electric zinc smelting, which has engaged a good deal of attention during the last 15 years, is metallurgically of the same nature as ordinary smelting: the main difference is that, in one case, the zinc is distilled by the heat of the electric arc or the heat of electric resistance; while, in the other case, it is done by the combustion of coal. So far, electric smelting has become an art only in Sweden and Norway, where several thousands of tons of spelter are annually produced by this method. The smelters in Sweden and Norway enjoy very cheap power, whereby they have been able to overcome, or at least meet, the main obstacle that has heretofore prevented electric smelting from becoming a commercial art elsewhere.

EXTRACTION of gold and silver at the Tonopah-Belmont mill is the following in each department: in stamp-battery, 34.4% Au, 5.3% Ag; in tube-mills, 40.7% Au, 10.28% Ag; concentration, 6% Au, 9% Ag; in lower thickeners, 3.1% Au, 9.33% Ag; in first six agitators, 9.4% Au, 50.99% Ag; in upper thickeners, 1.2% Au, 2.0% Ag; in second six agitators, 0.3% Au, 4.3% Ag; and in stock-tank and filters, 1.25% Au, 1.56% Ag, a total of 96.35% and 92.76%, respectively.

A 155-OZ. GOLD NUGGET was found at Ora Banda, 40 miles from Kalgoorlie, Western Australia, in July. Others found in that State since 1888 are as follows: 127, 100, 480, 298, 333, 463, 487, 372, 168, 197, 168, 109, 51, 230, and 180 oz., respectively. Many of these were found in dry-washing.

What is Flotation?—II

By T. A. RICKARD

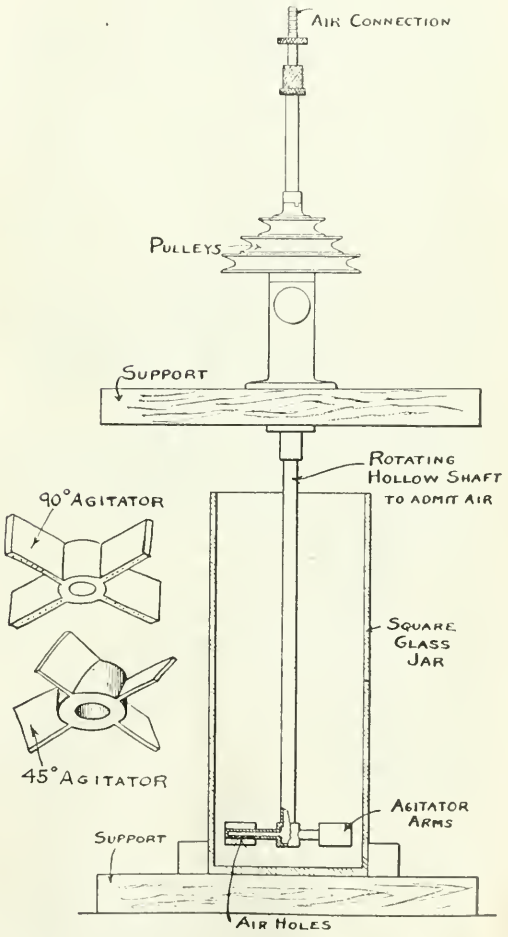
All of the natural phenomena, or appearances, described at the beginning of the previous article, play their part in flotation and each of them has served as the basis for one or other of the many patents that have involved the subject in a maze of vindictive litigation.

Surface tension is the idea underlying Hezekiah Bradford's patent of 1886. In this process the dry powdered ore is caused to meet the surface of a still body of water, so that the metallic particles, which are not wetted, are made to float away, while the gangue particles, which are wetted, sink. This was the first application of flotation without the aid of oil.

In 1904 A. P. S. Macquisten invented a tube apparatus in which surface tension is utilized for concentration. In 1906 the process was applied on a working scale in the Adelaide plant at Golconda, Nevada, where chalcopyrite was separated from a lime-garnet gangue. In 1911 the Federal Mining & Smelting Co. adopted the process for the Morning mill, at Mullan, Idaho, in the separation of blende and galena from a quartz-siderite gangue. At Golconda 96 tubes treated 125 tons per day; at Mullan, 119 tubes treat 150 tons. The iron tube is 6 ft. long by 12 in. diameter. The interior is cast with a helical groove. The tube is revolved at 30 r.p.m. Success appears to depend upon the angle at which the metallic particles are presented to the surface of the water. Subsequently, the water at Golconda was slightly acidified, so that it must have caused an ebullition of carbonic acid gas from the lime in the ore. Thus the bubble phenomenon may have come into play. Later, small additions of coal-oil were made, so that another phase of flotation was introduced. In the first instance, however, the Macquisten tube was a real surface-tension process.

In 1905 H. L. Sulman and H. F. K. Picard obtained a British patent for a similar process, but it was a failure. As the floating particles are in the nature of a film, or "in patches one particle thick," the area of the separating surface has to be large and still. Moreover, some gangue-minerals are floated as readily as the metallic parts of the ore.

In 1912 H. E. Wood described his method of concentration, by the surface tension of water alone, in a paper read before the American Institute of Mining Engineers. In common with other metallurgists, he had noticed that dry particles of sulphide minerals are "good swimmers." In all gravity work, we try to drown them. He had also proved for himself that the oxides are easily wetted. Thereupon he devised a machine in which the dry-crushed ore is fed in a thin stream from a vibrating plate onto a current of water. An impetus is given to the surface by small water-jets. By retarding the current the gangue is made to sink, while the film of sulphides remains on the surface. The elasticity and tenacity of this film is remarkable. The process is being applied on a commercial scale to molybdenite ores by the inventor, Mr. Wood, at Denver. He has also made experimental demonstrations on graphite, tellurides, and other lustrous minerals. At the San Francisco del Oro mill, in Chihuahua, Mexico, 12 of his machines are in use on an ore that has defied other efforts at concentration.



THE SQUARE GLASS JAR MACHINE FOR MAKING FLOTATION TESTS.

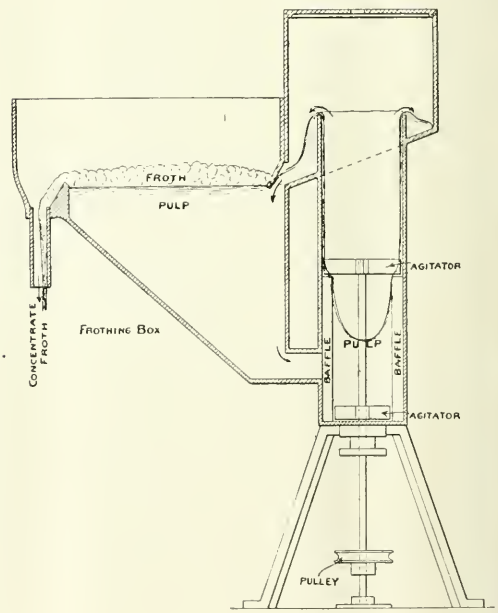
Bulk-oil flotation was invented by Robson & Crowder in 1894 and developed successfully by Francis E. Elmore, whose British patent was obtained in 1898. In the Elmore process the crushed ore is mixed with several times its weight of water. With this pulp a weight of oil equal to, if not exceeding, that of the ore, is mixed gently, so as not to break or emulsify the oil. The oiled mass is run into a spitzkasten, where the oil rises to the surface, buoying the metallic particles, while the gangue and water are removed at the bottom. While oil is described as the prime agent, it is probable that air, entrained by agitation, increased the buoyancy of the concentrate.[1]

Oil and Air. Coming to processes using a combination of oil and air, we have the Everson patent of 1885. Carrie J. Everson was washing some sacks in which concentrate had been shipped to her brother's assay-office at Denver when she noticed that the sulphide particles floated on the water. It is said that the sacks had become greasy, but it is quite likely that she used soap, in which case the greasiness is not required as an explanation. In her process the maximum addition of oil, namely, 18%, is less than one-sixteenth of the quantity required for bulk flotation. As to air, that she obtained by the agitation of the pulp by means of two fans radiating from a hollow revolving tube. The result—according to a description written in 1890, not in the light of prejudiced observation today—was the formation of a "thick scum of sulphides" that "rose to the surface and was skimmed off, leaving the hitherto black ore as white as snow."

The original bulk-oil process of Elmore had numerous applications, some of which were fairly successful, but in 1904 it was displaced by the Elmore vacuum process, in which flotation by bulk-oil was subordinated to the buoyant effect of air-bubbles generated from the oiled mixture while under a vacuum, and by heating. Under normal conditions water holds in solution an amount of air equal to 2.2% of its volume. This is liberated under a vacuum, but neither the amount of air released (especially at high altitudes) nor the quantity of oil used suffice to explain the degree of flotation achieved, as measured in weight of concentrate. The presence or the addition of limestone or other carbonates, with the use of acid, suggests the aid of bubbles of gas other than air. The proportion of oil in this process has been decreased gradually from 10 lb. per ton of ore to as little as 2.7 lb. per ton. As the mixing involves violent agitation, it seems inevitable that entrained air plays a part.

To the 'oil and air' process we must add that of Edmund B. Kirby, for which patent was applied in December 1903 and granted in January 1906. Kirby experimented on ore from Rossland, British Columbia. He used a large proportion ("one-fourth to three-fourths as much, by weight, as ore") of oil; he added acid; he employed heat; he "thoroughly agitated"; he "injected air into the mass"; and he obtained "a floating scum of hydrocarbon liquid, air, bubbles, and concentrates." In the light of later events it is claimed that he must have made a 'froth,' because the oil was insufficient to cause bulk flotation and the agitation sufficed to entrain enough air to produce a froth. To this the patentees of the so-called 'agitation-froth' process reply that his "scum" was not a "froth" in *their* sense of the term. That he produced froth seems highly probable; but to say that 'scum' and 'froth' are the same thing, is, in my opinion, not correct.[2]

Bubbles. Meanwhile the bubble methods of Charles V. Potter and Guillaume D. Delprat had been patented



THE JANNEY FLOTATION MACHINE.

in 1902. In these processes gas was chemically generated with a view to promoting the flotation of metallic particles in Broken Hill ore. This Australian ore contains calcite, which by the addition of acid, emits bubbles of gas that adhere to the sulphides. Potter used acid, agitation, and heat, while Delprat employed a hot solution of salt-cake or acid sodium sulphate and sulphuric acid. Both processes were successful on a large scale, particularly Delprat's, which is still in use at the Broken Hill Proprietary mine. Neither used any oil. The bubbles attach themselves to the sulphide (blende and galena) particles and carry them to the surface,

[1] A suggestion that is confirmed by the statement of Walter McDermott that "in practice [of the Elmore process] the agitation with the pulp results in the oil taking up a very appreciable quantity of air, giving a certain sponginess, with natural increase in floating power." 'The Concentration of Ores by Oil.' *E. & M. J.*, February 14, 1903, page 262.

[2] 'Scum' is the impurity or extraneous matter that rises to the surface of a liquid, such as the vegetal film on a stagnant pond or the dross on a bath of molten lead. 'Froth' is a multiplicity of bubbles.

whence they flow with the liquor into a compartment where, the bubbles breaking, the metallic freight is dropped, and collected as a mixed concentrate. T. J. Hoover says[3] that "the result of the manipulation to which the material is subjected is the formation of a dense froth of bubbles and mineral"; but this was published in 1912, and must be read in the light of events long subsequent to the claims made by either Potter or Delprat. In order to explain the making of froth without oil, he suggests the presence in the ore of such substances as "yield gummy organic compounds that selectively adhere to the ore." This is an important suggestion. Be that as it may, the Potter and Delprat methods demonstrate that flotation is practicable by the aid of bubbles without the addition of oil.

In the Froment process, patented in Great Britain and Italy in June 1902, the bubble idea is dominant, for, while Alcide Froment used oil, he employed it to attract the bubbles of gas generated by the reaction between acid and calcite, adding the latter if suitable carbonates were lacking in the ore. He emphasized the fact that not only have the lustrous metallic particles an affinity for films of oil, but the oil itself attracts bubbles of gas, both air and carbon dioxide. He recommends much less oil than had hitherto been used, namely, "a thin layer of oil," which has been interpreted, according to the exigencies of litigation, to mean anything from less than 1% up to 14%, according as the Froment patent was being upheld or attacked. In Froment's later instructions to the purchasers (Minerals Separation Ltd.) of his patent he mentioned the quantity as from 1 to 3½%. For a 5% sulphide ore, the oil would weigh 20 lb. per ton. This question of the quantity of oil required by Froment has been much discussed, but the dominant idea in his mind appears to have been the affinity of oiled particles, necessarily sulphides or lustrous metallic particles, for bubbles of gas. These he obtained by agitation (air-bubbles) and by adding both acid and calcite (bubbles of carbonic acid gas) to the pulp. As to what "a thin layer of oil" may mean, I do not know what Froment meant by the expression, but the scientific meaning of the phrase is indicated by the fact that oil when dropped on the surface of water will spread out in a film one molecule thick.[4]

REDUCED FACSIMILES OF ILLUSTRATIONS ACCOMPANYING TWO FAMOUS PATENTS.

The agitation of the ingredients specified by Froment will produce a froth; therefore, to the detached onlooker, it is difficult to distinguish the essentials of his process from those claimed in the basic patent of Minerals Separation. Mr. Sulman called the Froment froth a "tender and evanescent assemblage of bubbles of carbon dioxide carrying mineral," but if it carried mineral I do not see that his refusal to call it 'froth' is of any great consequence to those of us who are not interested in the litigation.

Coagulation. Here we come to what is apparently a break in the sequence of inventiveness, for, beginning with November 1902, Arthur E. Cattermole obtained a succession of patents for a process in which the idea of oil-selection is used to sink the metallic particles of an ore, not to float them. To an acidified pulp he added from 4 to 6% "of the weight of metalliferous matter present," not of the ore as a whole; therefore, with a 12% zinc ore this would mean 0.48 to 0.72%, say 10 to 15 lb. oil per ton of ore; and with a 2% copper ore, it would mean only 1½ to 2½ lb. of oil. But this oil "is brought into the condition of an emulsion in water containing a small percentage of soap or other emulsifying agent." These are the words of his most important patent, U. S. No. 777,273, dated December 13, 1904, but in his first patent, British No. 26,295, of November 28, 1902, he gives the proportion of soap as 2%. When this mixture of ore, acidulated water, and soapy oil is agitated violently the metallic particles are agglomerated into flocculent masses that sink, the separation from the gangue being then effected by an up-current of water. To facilitate the separation, the mixing was conducted in two stages, of which the second is said to have been "a rolling form of agitation." Cattermole called his agglomerate a 'granule'; Froment called it a 'spherule.'

Froth. The Minerals Separation company was organized in 1903 to acquire the Cattermole invention and thereafter his patents became part of the property of that company. The first and only plant to use the Cattermole process was erected on the Central mine at Broken Hill,[5] where it was soon displaced by the so-called agitation-froth process of Sulman, Picard, and Ballot. These gentlemen have testified that they made their discovery by experimenting with the Cattermole process, applying scientific methods of research, based on the fact that sometimes "loose flocculent masses of partially granulated sulphides" would rise, instead of sinking. Finally, they decided that this was due to insufficient oil. The actual experiments were made by Arthur H. Higgins, who, by diminishing the amount of oil to 0.62% on the ore, caused so many of the metallic particles to rise that a high recovery was obtained by flotation. H. L. Sulman says that by reducing the amount of oil the granulation was stopped and "coincidentally a mineral froth began to take its place." This was in March 1905. Whereupon the basic patent of Minerals Separation, British No. 7803, of April 12, 1905, was taken out by H. L. Sulman, H. F. K. Picard, and John Ballot, and subsequently they obtained the U. S. patent No. 835,120 of May 29, 1905, issued on November 6, 1906. In this patent reference is made to the Cattermole patent and it is claimed that the 'granulation' characterizing his method is stopped by reducing the amount of oil to "a fraction of 1% on the ore" and that by vigorous agitation the oil-coated particles are caused "to rise to the surface of the pulp in the form of a froth or scum." The use of 'scum' here is unfortunate for Minerals Separation, for it tends to identify the 'froth' made by this process with the 'scum' made by most of their predecessors in the art. In this patent acidulated water, warming of the mixture, oleic acid from 0.025 to 0.5% on the ore, oleic-soap solution, the formation of the froth, and the separating of the froth from the remainder of the solution are specified. Since this patent was issued the process has been applied successfully, and on a large scale, in many parts of the world, notably Broken Hill, Great Cobar, Great Fitzroy, Chillagoe, and Wallaroo, all in Australia; also the Braden copper mine in Chile; and more recently at the Inspiration, Anaconda, and other important mines in this country. It is proper to add that a froth-flotation process is used successfully at the Butte & Superior, Miami, and other mines, but the users deny that it is a method to which the Minerals Separation company has proprietary rights. The difference of opinion is yet to be settled by the Courts.

In the foregoing review, I have omitted reference to a number of flotation patents, some of them interesting, because the multiplication and repetition of detail would be only confusing. It will be noted that the amount of oil per ton of ore has decreased from over a ton[6] to less than half a pound. From an insistence upon the use of acid in all the patents, even to the last quoted in the above summary, we come to the recent fact of flotation in alkaline solutions. Indeed, in the case of the Mexican mill we are told that the deleterious effects of soluble sulphates was overcome by an excess of oil.[7] How much of the oil used in the prior art was due to excess of acid, it remains to be stated by an independent investigator. Much of the early work with flotation was done on Broken Hill ore, which contains a notable proportion of carbonates, hence the addition of acid proved a help, by generating gas, not only in the Potter and Delprat processes, but in others also, namely, those using oil. One ingredient, however, has gained progressively in importance: air. Other gases have had their day, some generated chemically, others electrolytically, but in the latest phase of the process the prime agent is air. Indeed, the good results ensuing from the lessened proportion of oil may be due to the fact that the less the oil the

greater the intensity of agitation to cause it to spread throughout the pulp.[8] The vigorous agitation, so often emphasized, may have been like the shot that was aimed at the crow and killed the pigeon, for it must have done more than mix the ingredients: it resulted in entraining and atomizing a large volume of air. The later history of flotation suggests that a day may come when the oil, like the acid, may be found non-essential, and in its place will be added the ingredient that supplies the substance required for making bubbles. To make bubbles the surface tension of the water in the flotation-cell must be decreased by a contaminant and at the same time the viscosity of the liquid must be strengthened. Oil is not the only substance that can perform these functions. Some alkaline compound may be found that will do the trick. In the Cattermole, Sulman & Picard patent (U. S. 777,274) a fatty acid is produced *in situ*. In another patent, by Sulman, Greenway & Higgins (U. S. 962,678) a claim is made for the use of "an organic compound contained in solution in the acidified water" as a soluble frothing agent. In U. S. 1,055,495, Schick claims the use of carbon tetra-chloride to promote 'levigation,' or flotation. In U. S. 770,659, Scammell employs sulphur dioxide as a means for increasing the viscosity, and in U. S. 744,322, Foote uses slaked lime. Among other nostrums, alcohol, phenol, camphor, amyl acetate, benzoic and lactic acids, and calcium chloride have been suggested in various patents. In some cases, possibly, an ingredient of the ore itself may suffice. Meanwhile the element of time found essential to a good formation of froth suggests that the delay is useful in increasing the viscosity. Mere speed of agitation and aeration does not seem to suffice. But sub-division of the air helps. This reminds us that T. J. Hoover and Minerals Separation took out a patent, in Great Britain in 1910, for the introduction into the oiled pulp of air and other gases through a permeable medium, but it was not deemed worth while to obtain a patent in the United States. Knowing nothing about this, J. M. Callow hit upon the same idea and designed the porous bottom now in use at many flotation plants.[9] Cattermole used an ordinary cone or Gabbett mixer fitted with baffles. Froment employed a mixer of the egg-beater type. Sulman & Picard in one of their patents (U. S. 793,808) suggest an agitator made of a coil of perforated gas-pipe, through which compressed air and oil are fed. Centrifugal pumps, Pachuca agitators, air-jets, and pans with mechanical stirrers have been adopted by various inventors. Other devices for causing agitation and promoting aeration of the pulp have been, and are being, introduced. These, fortunately, are not likely to invite litigation, for most of them have been used already in metallurgical processes, notably cyanidation, in which oxidation by air is essential.

REDUCED FACSIMILE OF HYDE'S PATENT.

Iron pyrite is often found in the 'clean-up' of gravel mining. In a Trinity County placer mine the amount was so large as to excite the curiosity of the manager. On investigating he found that clusters of fine crystals surrounded and adhered to fragments of waterworn slate and even to pieces of smooth water-worn gold. This association seemed to indicate that the pyrite is formed in place by percolating water. At Taxco, Mexico, a similar occurrence of freshly-formed pyrite in gravel was noted; in this case the pyrite was more abundant and carried so much silver that the whole bank of gravel assayed from 2 to 2½ oz. silver per ton. Prof. A. F. Rogers of Stanford University, to whom these occurrences were reported, states that it looks as though this pyrite may have been of recent formation. He finds a record of similar phenomena at Sulphur Springs, in Arkansas, at Carlsbad, in Bohemia, and in Iceland. Whitman was able to form pyrite from percolating water at a temperature a little above the ordinary; this experiment shows that the Trinity County pyrite mentioned above has probably been formed where it was found and has not been transported from a distance. Similar occurrences are mentioned in Lindgren's 'Mineral Deposits.'

[8]Dudley H. Norris has several patents for the use of water containing, in solution, air under high pressure for intensified bubbling, with or without oil.

[9]M. & S. P., May 29, 1915, page 826.

Mine Ventilation

At the Copper Queen mine, Bisbee, Arizona, the Spray, Gardner, Lowell, and Sacramento divisions are ventilated entirely by mechanical means. After the pressure and exhaust systems of ventilation were carefully studied, according to Charles A. Mitke, in a paper to the A. I. M. E.,* the former method was adopted. In this system, all mine fans were placed underground on the deepest working levels of the different divisions so as to draw the air down the intake shafts, force it through the workings and stopes, and exhaust it to the surface through upcast shafts.

The reasons for adopting the pressure instead of the exhaust system are as follows:

1. More practical. Since all the deep shafts of the Copper Queen are in operation and a large amount of work is done around each, as for example, men going on and coming off shift, handling timber, tools, and supplies, etc., it would not be practical to have an exhaust fan on the surface near the collar of the shaft. In the Gardner, a subway below the collar of the shaft would be out of the question. Consequently, a large air-tight chamber, inclosing nearly the entire head-frame, would have to be built if a suction fan were used.

2. Better control of mine fires. The pressure system is the more advantageous in case of mine fires. With this arrangement, the entire workings are under pressure, and the gas or smoke from a mine fire may be coursed to exit through neighboring shafts that are not in operation. Since the air is under considerable pressure at the bottom and sides of the present fire districts and each of the outlets over them is provided with regulator doors, the quantity of air passing through the fire zone can be increased or diminished at will, and consequently the fire can be brought under control more readily than with the exhaust system.

3. Greater efficiency. Since the Spray, Gardner, Dallas, and Sacramento shafts are natural down-casts, the mine fans were placed underground so as to take advantage of these circumstances and multiply the volume of the natural down-cast from five to ten times. The pressure system, therefore, has the advantage of the additional natural ventilation, which evidently would be lost with the other system; and more power would be required for the same quantity of air if the natural down-casts were changed to up-casts by suction fans.

4. Greater safety. Experience in the Lowell mine fire showed that in the event of the connections being closed between the fire and the suction fan, there is a possibility of smoke and gases entering the workings below and endangering the men. In the adopted system, the maximum air pressure is below the fire district, which makes it impossible for gases to go down, even if bulkheads of a sealed fire district should be opened suddenly by caving ground. At present a churn-drill hole is being put down to a depth of 1100 ft. over the old Lowell fire stopes. When this is completed water will be run in to cool the area. No trouble is anticipated, since this was thoroughly tried at the Holbrook, where a large amount of water was turned into churn-drill holes, and no smoke or gases were taken down against the pressure of the mine fan.

Advantages of New Ventilating System. (1) A smaller quantity of compressed air is used for ventilation. (2) All possible natural ventilation is utilized, and the general direction of air currents is the same for both natural and mechanical ventilation. (3) There is a decrease in temperature, and a lower percentage of humidity and CO_2 throughout the mine, which means healthier working conditions. (4) A saving of eight 5-hp. blowers was made, as these have been removed from the mine. (5) The five lower divisions are under pressure, which partly acts as a check in preventing some mine fires from crossing the Copper Queen side-lines, as for example, the proximity of one mine fire near the Gardner workings. (6) Less decay of mine timbers. (7) The volume of air has been increased from 60 to about 300 cu. ft. of air per man per minute. (8) Formerly a large amount of moisture kept the timbers and working places in a damp condition, and fungus also covered most of the timbers. Since the mine fans were started, a large amount of water is removed daily from each division by the air currents, so that the mine is comparatively dry and the growth has disappeared. (9) The increase in velocity and volume of air resulted in the greater efficiency of the men. And (10) the new ventilating system is advantageous to the mines adjacent to the Copper Queen; there is a great deal of broken and stoped ground along side-lines, permitting a large amount of air to escape through these avenues and ventilated stopes beyond the Copper Queen boundary.*

*'Ventilation of the Copper Queen Mines,' by Charles A. Mitke. Bulletin No. 105, American Institute of Mining Engineers, September 1915.

Carbide Lamps in Mines

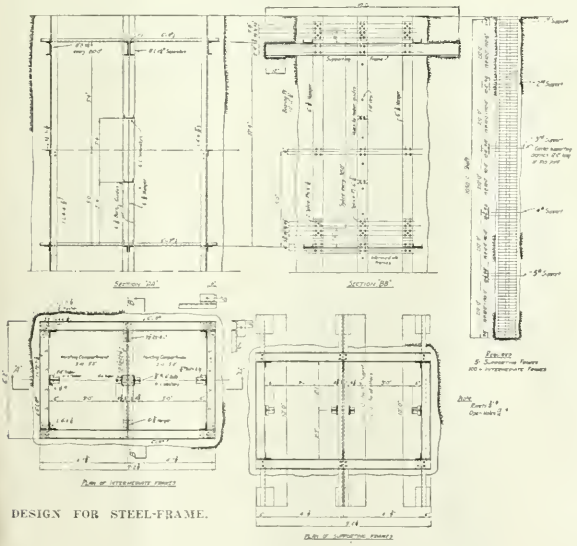
A type of open-flame cap lamp for burning acetylene gas, the gas being made within the lamp by the action of water on calcium carbide, and known to miners and the trade as 'carbide lamps,' has come into use in metal and coal mines of the United States in recent years. In some non-gaseous coal mines the open-flame oil-lamp, and in many metal mines the candle, has been replaced by this lamp. Fully 300,000 acetylene lamps are in use in mines of this country, 60% in coal and 15 to 20% in metal mines being of this type. A carbide lamp gives better light than a candle or oil-lamp, and so should reduce the number of accidents; it is clean and the flame produces little smoke; the gases of combustion are principally carbon dioxide and steam, and the acetylene is not injurious to health; the flame does not drop sparks that might ignite explosives, but the flame will set fire to anything quicker than the flame of an oil-lamp or candle; the general efficiency underground is better on account of better light; and the cost of upkeep is lower than that of the other lights.—James W. Paul in *Miners' Circular* 18 of the U. S. Bureau of Mines.

Steel Shaft-Timbering at Los Ocotes

By R. H. CROMWELL

*The Los Ocotes copper mine in the State of Oaxaca, Mexico, had been developed over a period of a number of years principally by the San Juan shaft. This shaft started as a small prospect working on the vein. It was more or less crooked and irregular in cross section, but as the ore was found to continue in depth it had been sunk intermittently in preference to starting a new and more elaborate shaft.

When 600 ft. in depth had been reached it was decided to sink 200 ft. deeper and then equip the shaft for regular extraction of the ore developed. From the 600 to the 800-ft. level the shaft was sunk two-compartment size. It was carefully plumbed from the surface, and the sinking was carried on in such manner that the cross-section of the shaft from the 600 to the 800-ft. level would square up with the proposed enlarged and straightened cross-section of the shaft from the surface to the 600-ft. level. The rock was quite solid, lagging being required in only a few places.

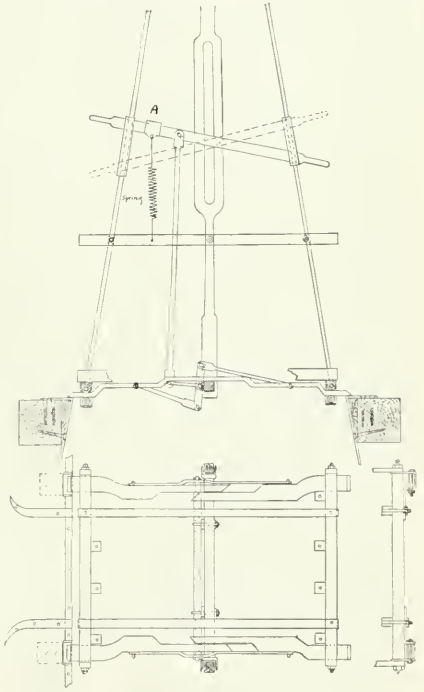


DESIGN FOR STEEL-FRAME.

Timber in this shaft rots quickly, even when protected with coal-tar; timber sets could not be relied upon to last more than three years. A considerable body of ore had been developed, and it was therefore assumed that the shaft would be used for a number of years. For these reasons it was decided to equip it with a steel headframe and steel timbering.

*Abstract from the *School of Mines Quarterly*, Columbia University, No. 2, 1915.

In enlarging and straightening the shaft from the surface to the 600-ft. level, it was found most advantageous to work from the surface downward. A heavy swinging wooden platform or *balsa*, about the size of the finished cross-section of the shaft was constructed, and was used for supporting the men engaged in carrying down the enlarging benches in the shaft. This platform was swung from four cables attached to its corners and joining in a central single cable operated by a small hoist on the surface. Before a round of holes was fired the platform could therefore be raised and quickly lowered into place again after blasting. This saved a good deal of time and at the same time protected the steel timbers. As ventilation in this shaft was excellent, after a round of holes was fired, but little time was lost in lowering the *balsa* and getting a new round of holes started. As the trimming and enlarging of the shaft proceeded downward, bulkheads were put in successively at the different levels below the point where trimming was going on. From these bulkheads the material blasted from the shaft was removed currently and stored in the different



AUTOMATIC CHAIRS FOR MINE-CAGE.

levels, from where it could be economically hoisted when the steel head-frame and shaft-timbering was complete.

We first attempted to use air-hammer drills mounted on light columns for the trimming and enlarging of the shaft, but it was found that the natives lost too much time in preparing set-ups and making connections. Better progress could be made by hand-drilling, as in some cases only short holes were required. About 6 ft. of shaft was trimmed per round. The men would shoot whenever a round of holes had been completed. Plumb-bobs from the four corners of the collar of the shaft were lowered to the trimming bench after each round of holes was fired, the position of the new holes being determined by the plumb-bobs. During trimming operations, water was being removed from the bottom of the shaft by a small Cameron pump driven by compressed air. Before blasting, lengths of both water-columns and air-pipes were removed at the point in the shaft where the round of holes was to be fired. After these holes were blasted and the loose ground barred down, the pipes were replaced and pumping resumed.

The steel timbering shown in the drawing, was put in as fast as the trimming of the shaft progressed. The ends of the flat 6 by $\frac{3}{8}$-in. hangers, to which the sets were bolted, were maintained at sufficient distance from the trimming-bench in the shaft so that blasting could not injure the steel timbers. They were also protected by the *balsa*, which, before each blast, was always raised from the bench to the bottom of the steel hangers.

The drawing shows supporting sets of 8-in. steel channels which were cemented into steps and into the sides of the shaft. These supporting sets, from which the steel timbering hung until securely wedged to the sides of the shaft with blocking, were installed just below the collar and at 210-ft. intervals in the shaft.

All the steel, before being installed, was painted with a mixture of coal-tar and turpentine. The steel went together rapidly and without difficulty, and after each set was blocked up the whole structure was rigid. From the surface to the 600-ft. level, sets were put in 10 ft. apart. From the 600 to the 800-ft. level, as the ground showed a tendency to cave, sets were put in every 5 ft. and lagged with 2-in. planks laid lengthwise between sets.

For the timbering of this shaft, about 73 tons of steel was required, costing approximately $100 U. S. currency per ton, laid down at Los Ocotes mine. The steel head-frame contained 15 tons of steel, which cost about $140 per ton laid down at the mine.

In connection with the equipment of the shaft at this mine it was planned to use chairs attached to and operated from the cages. Referring to the sketch of this arrangement, a weight or spring at A automatically withdraws the chairs when the cage is raised and its weight taken from them. The arrangement was devised by John Martin of Tariche, Oaxaca, and has proved satisfactory at the San Juan mine of that place. It has the advantage of avoiding the expense and danger of having sets of chairs at each of the levels from which hoisting is being carried on. In operating the automatic cage chairs, the cage-man holds the lever against the action of the weight and spring until the protruding chairs rest upon the landing and are held in that position by the weight of the cage.

Brazilian Mining Titles

In 'Mineral Resources of Minas Geraes,' A. F. Calvert states that "it has been proved beyond all shadow of a doubt that Brazil possesses an incalculable wealth of mineral treasure"—nevertheless "the Brazilian mining industry at the present moment is in an almost moribund condition."

Mr. Calvert explains, on the authority of *The Times* that this incomprehensible neglect is due in the main to bad legislation, and to the fact that the adventurous life of the gold-seeker appealed to but few Brazilians and he also gives other reasons that seem inadequate to account for the neglect of mining in Brazil. We say the reasons are inadequate, for similar causes have not prevented the investment of foreign capital in other regions of the world not as well situated as Brazil.

There is, however, an adequate explanation of the neglect of mining in Brazil, and one of the chief causes of this neglect is the lack of mineral deposits that can be worked profitably under existing conditions. In other words, not even in Brazil are diamonds, gold nuggets, and rich gold quartz-veins to be found tasily. Another potent cause that deters foreign capitalists from investing in Brazil is the great difficulty in obtaining title to real estate. We heard a most lucid, instructive, and amusing account of these difficulties in an after-dinner speech by a noted American geologist who is thoroughly familiar with Brazil. An instructive after-dinner speech is so rare that we remember the details very distinctly. The speaker explained that when a greenhorn buys a mine in Brazil, the titles seem to be all right and there is no difficulty in acquiring possession of the property. After a reasonable interval, however, a pleasant gentleman appears and inquires why the foreigner is working on his property. Investigation shows that the claimant has good ground for his assertion and he is bought off as cheaply as possible. But no sooner is he disposed of than claimant No. 2 appears, and so on until the foreigner becomes disgusted and departs for some country where some form of title registration is in force. The trouble with the Brazilian titles arises from the granting of vast concessions in the early days to the pioneers. These pioneers usually had large families and the estate descended to the family as a whole and not to any individual. As long as the ownership of the land is confined to the descendants, some basis of agreement is reached by which Manuel Silva can have the part he occupies and Juan Fernandez can retain his portion, but when the foreigner arrives every member of the family must be dealt with individually, and with a large family the result is financially ruinous. This difficulty of obtaining titles is, of course, not insuperable, but the acquiring of a good title needs more time, money, and patience than the average European or American possesses.

Practical Ideals

By GEORGE OTIS SMITH

*Men agree that times change. But whether we are reviewing geologic eras or epochs of human history, it is true that certain of these periods of time are characterized by much more rapid change than are others. Neither the rate of earth evolution nor that of human progress has been constant. In this twentieth century we look out upon an environment peculiarly adapted to the rapid generation of ideas and their almost instantaneous world-wide dispersion. An idea can encircle this globe in a few hours, and within the week, stand out on the printed page in all the languages of the civilized world.

"Practical ideals" is thus more than an apparent contradiction of terms—it is the real thing that the world demands. The practical ideal is the ideal in its everyday form that has the power to uplift because it is firmly braced on the ground. Just as the facts of the mine and furnace and rolling-mill must be used in the laboratory of the technical school, so on the other hand the ideals of the university need to be taken into the market-place. Here is the proving-ground where theory encounters fact, and where opinions are put to the acid test of experience.

Present-day reformers like William Allen White and Shailer Mathews have not been the first to proclaim that "the old order changeth, yielding place to new." Down through the centuries of recorded history, while human nature has remained much the same, social conditions have changed almost without pause. Many reforms, however, are now being realized so rapidly that what is a commonplace in 1915 was at best only a vision when this century opened. The 'impossible' is being enacted into effective law so frequently now that only the blind can fail to read the signs of the times.

Last winter at a Senate Committee hearing when water-power legislation was under discussion, the usual conflict of thought developed between the lawyers who cited the limitations set by the Constitution, and those of us who urged the needs of the public. In an attempt to define this antagonism of opinion, I repeated to the Committee my remark to an eminent lawyer after hearing his constitutional argument. "It seems to me that the chief difference in our point of view," I said, "is that the student of the law thinks what cannot be done ought not to be done; while others of us believe that what ought to be done can be done"; or as I would express it tonight, the ideal can be made practical.

These rapid changes in the social order, of course, necessarily follow the increasing complexity of civilization, yet I venture to suggest that none of us comprehends the full extent of these changes in commerce and industry. It has been figured that it would take a caravan of half a million camels to transport the wheat which in a single day passes over any one of our great railroad lines during the season of crop movement. And when it comes to the product of our coal mines, which furnish the staff of life to America's industries, the camel as a unit of transportation cannot be used in any simple calculation; for a year's output of the coal mines of this country would fill more than eleven and a half million of our largest coal cars, or a train long enough to encircle the globe three times at the equator.

I am hinting at the differences between the world of today and that of yesterday; you students of engineering science know how rapid is the march of improvement in industrial processes and methods. The scrap-heap is piled high with machinery that only a few years ago won and deserved the admiration of the world, but that is now displaced by something more efficient. And all this progress has affected the problems of government, and more particularly those of a democratic government. Changes so marked in the material or business environment compel social and political reconstruction.

The new political economy, as I see it in the making, is putting a larger emphasis upon the interdependence of all members of the community—in fact, it is the community idea that stands out. The brotherhood of man is an ideal constantly preached to mankind for nineteen centuries, but now this ideal has become a practical factor in affairs of State. The moral element in the economic questions before the public is not to be overlooked, and recent progress in this respect has been most striking. Take for illustration the law protecting women factory-workers: on the question of its constitutionality the highest court of New York reversed itself within eight years, the justices holding that the health of woman is a matter of vital importance to the State. Within these few years the attitude of both the public and the court has radically changed.

The intimate union of the practical and economic with the ideal and moral may be seen also in the liquor question. Most striking of the war measures taken by the great European nations have been those aimed against the drink habit—simply in the aid of efficiency. So, too, in this country, the political question of suppressing the liquor traffic has become hardly less an economic than a moral issue. The interest of the citizen in his fellow's welfare thus becomes real and active in a highly organized democratic civilization.

The extent of the share which the consuming public has in the conduct of certain industrial operations on a large scale is being recognized in the courts. In a recent decision in New South Wales, for instance, the court upheld as legal and in the public interest, certain trade agreements among coal-mining companies and shipping companies. From New South Wales it is a long, long way to Illinois, yet the conditions in the coalfields of these two States may not be altogether diverse. In that far-away country, cut-throat competition had followed the development of a new field with the result that prices prevailed which the court described as disastrously low.

*Part of an address delivered at the Annual Joint Meeting of Sigma Xi and Phi Beta Kappa, University of Illinois, May 4, 1915, by the Director, U. S. Geological Survey.

The justification of the combination was stated by the court with a logic that appeals to the non-legal mind. "The consumers of coal will lose in the long run if the colliery proprietors do not make fair profits or the miners do not receive fair wages."

Coming back to the same problem nearer home, I may mention a fact which may not have been given publicity. More than once in the last six years strong delegations representing large bituminous coal-mining interests have come to Washington seeking authority for a trade combination. The purpose of such a combination was not concealed—it was to raise the price of coal so as to make the business truly remunerative; but in order to secure a price properly related to cost, these hard-headed men of 'big business' proposed that the fixing of that price should be absolutely under Federal regulation. I believe they had a good case, and although they urged something for which the times were not ripe they were in fact presenting a proposition promising as much to the public interest as to their private gain—this will be a practical ideal as soon as legislation catches up with business.

The competitive element in business need not be thrown aside—it has not outlived its usefulness. But competition must be fair. For big business or for little business, government should lay down the rule that the winning of a market naturally follows the proffer of better quality or lower prices. The buyer, whether he lives in a South American city or on a New England farm, wants the most and the best for his money. Enforce this rule, and trade competition will resolve itself into a contest decided by the constructive contributions made by the inventive organizer and the skilled laborer. In short, the goal of fair competition is excellence of product secured through efficiency of producer.

Regulation by the Government, moreover, means the protection of the corporation as well as of those served by the corporation. The fear that the courts could not safeguard the interests of all has proved groundless. Two recent decisions by the Supreme Court may serve to illustrate this. The public service character of a railroad does not exclude the essential idea of a reasonable reward. Government control, whether State or Federal, cannot be arbitrary; facts of profit and loss must control questions of rates. In the Norfolk and Western case the Court decided that the fixing of a two-cent rate is not justified if thereby merely a nominal profit is earned on the interstate passenger business. The Northern Pacific decision is even stronger in the Court's limitation of legislative powers. North Dakota had sought by statute to fix rates for coal that would promote utilization of the lignite of that State, a policy in line with conservation. The Court, however, states that the public interest cannot be invoked as a justification of arbitrary demands that require transportation of freight at less than the proper cost, or even virtually at cost, and thus deny to the railroad a reasonable reward for service. The public cannot even require a railroad to carry coal at a loss, on the supposition that the receipts for the carriage of wheat will show a profit on the freight business as a whole. The dominant principle is that the Government should protect the public user and private owner.

Most important is the contribution of the higher education to American citizenship. A few of you—let us hope many of you—may enter the public service and serve your home town, your State, or your nation as responsible and responsive public servants, efficient because expert, faithful because patriotic. To all of us, however, comes the opportunity and the obligation to be citizens and to take the duties of citizenship no less seriously than we would those of public office. It is you to whom the nation must look not so much for office-holding as for leadership in public opinion.

The compelling argument for engineers to step forward as citizens is the evident fact that politics has not kept pace with science. Take the political conditions of this or any other country, of this or any other day: they are characterized by uncertainty, confusion, and hazards that the business man would at once cut out of his own business and should eliminate from the nation's business. On the king's highway of ancient times, slaves worked without respite to make smooth the path for royal use, and today the American railroad invests millions to straighten curves or reduce grades, but on our political right-of-way, obstructions and obstacles which make all progress expensive, if not uncertain, are allowed to remain simply because these so-called institutions are our heritage from our fathers and our fathers' fathers. To look backward and to search for precedents seems to be more than a habit with statesmen; it is rather a part of their professional code.

Sigurd Ibsen, son of the dramatist, in his volume of suggestive essays entitled Human Quintessence, has used an expressive term—*the lag of politics*. As you students of mechanics might state it, the mass conditions of statecraft are expressed as inertia while those of science are expressed as momentum; the one is static, the other dynamic. As Ibsen himself states it: "What is called conservatism or maintenance of tradition consists in large part in efforts to lengthen the shadow life of bygone thoughts and orders: it is the past that shall decide for the present, it is the dead that shall rule over the living."

The most philosophic of American geologists, Professor Chamberlin, after studying exhaustively climatic conditions in the long geologic past and after weighing carefully the possibilities of disaster to our earth from collision with some star, has shown that we have good reason to measure the future habitability of the earth at millions or tens of millions if not, indeed, hundreds of millions of years. Sharing Professor Chamberlin's inspiring belief in the probability of racial longevity, do we not gain a real incentive to scientific research into the greater utilization of the forces of nature, an added argument for the application of the truths of science to civic progress, and a larger faith that the Golden Age is in the future—that the highest development of our country and of the world is to be witnessed by those who are to follow us? Are not our ideals practical and is not such a vision a call to larger service?

Manhattan, Nevada

By PERCIVAL NASH

*The geology of the Manhattan district shows that the main ore-bearing formations are sedimentaries, schists, limestones, and quartzites. North of the ore-zone of the district is found rhyolite, although in Slaughterhouse gulch, which is one of the boundaries of the known ore-zone to the north, a large intrusion of andesite exists, probably of the same age as the Tonopah andesites. Granite is found to the extreme south of the mineral belt.

The sedimentaries are considerably altered, owing to the granite intrusion, this being particularly the case from the Big Four mine eastward. From the extreme metamorphism shown, it is inferred that granite will be found to underlie the eastern portion of the district—the granite being older than the sedimentaries and younger than the rhyolite. The period of ore deposition probably followed the andesite intrusion.

Extensive block-faulting throughout the district complicates the structural geology. Accompanying the larger faults are found a series of smaller faults striking a few degrees east of north, and in these smaller faults most of the ore has been found.

Throughout the schist innumerable small veins are found, suggesting that the ascending mineral-bearing hot waters followed these fractures and spread into the schist, covering large areas. This is shown through the Gold Hill area, from the Big Four south through the Big Pine, Jumping Jack, and Mayflower properties. In the limestone belts also the ascending waters followed the main fault-channels and spread into the easily soluble limestone. The rich surface ores are due in part to secondary enrichment.

The White Caps claims are farthest east. The ore occurs in limestone in close connection with faults. The faults themselves do not contain much ore, which near the surface is oxidized; at a vertical depth of about 130 ft. it changes to a sulphide. The minerals found in the unoxidized ore, besides gold, are stibnite, realgar (sulphide of arsenic), iron pyrite, and a trace of copper. The gangue is a coarsely crystalline calcite; the limestone has been replaced by a dense dark quartz. An interesting feature is the almost total absence of silver. The faults dip west and southwest, and the orebodies appear to underlie the faults as if the fault-zones acted as a dam and impounded the mineral-bearing solutions into the limestone.

Three orebodies have been developed in the White Caps property; the eastern is much the largest as yet developed. It is about 130 ft. long and in places is 24 ft. between walls, the average width being 10 ft. From the middle orebody a large quantity of rich ore has been mined. West and south from the middle orebody, nearly 200 ft. distant, another large vein has been exposed. From the bottom, or 200-ft. level (vertical), this western orebody proves to be about 80 ft. long, averaging 8 ft. in width for most of its length, although in one place it is more than 20 ft. wide. A raise proves it to be 'blind', the orebody ending about 30 ft. below the surface.

The company's records show that 19,909 tons has been mined during the past three years, mostly by lessees, averaging $19.94 per ton. On the surface there is now about 6000 tons of ore awaiting milling facilities. The White Caps company has installed a complete mine equipment. A new vertical shaft has been sunk in the hanging wall of the orebodies in solid ground.

The Manhattan Consolidated property is in close proximity to the White Caps, and has developed a large orebody somewhat similar in character to that of the White Caps. The Consolidated has produced 9075 tons of ore, valued at $127,000.

Litigation hill joins the Consolidated on the west. The hill is about 2500 ft. long, of rounded nature, rising from the gulches on each side for a height of about 100 ft. for most of its length, but at its eastern crest being about 250 ft. from the floor of the valley. On this hill are found the Earl, Manhattan Amalgamated, and Litigation Hill Merger properties, consisting of five claims. A well defined bed of limestone traverses the full length of the above-mentioned hill, the course of the bed being east and west, with an average width of over 200 feet.

The lime is a coarsely crystalline carbonate and is readily soluble. In the deposition of orebodies, it has been replaced by silica and changed into quartz. The lodes developed by the Manhattan Consolidated in the eastern portion of this limestone are in east and west fissures that show strong fault-movements, interseeted by cross-veins along vertical fissures.

In the eastern portion of the Merger property the veins come together, and in several places chimneys of rich ore have been mined, in one case for a depth of over 500 ft. All three properties are equipped wth mining machinery, and considerable development has been done during the past three years. An important ore-shoot was opened between the Amalgamated and Earl properties at a vertical depth of 250 ft. Unfortunately, title to the orebody in question is undecided and for that reason neither company has attempted to extract the ore except in development. Litigation hill has yielded 9615 tons of ore of an average of $19.12 per ton, a gross value of $183,848.

The Gold hill area is in the centre of the district, and at present is the scene of the most important mining

*Abstract from *The Tonopah Miner*.

operations, the Big Pine open-cut work. On the crest of Gold hill is the Big Four property, with a fine mine equipment and a 10-stamp mill. The ore in this section is in a schist-zone, in places 50 ft. wide. The Big Four has a shaft sunk to 500 ft. The first large profits from the property were made by lessees. In the first 100 ft. of sinking, 100 tons of ore was mined averaging $325 per ton in the mill. The first lease also produced 1100 tons yielding $22 per ton. The second lease, which brought the Big Four mine into prominence, produced nearly $500,000. After the company took over the property, ore worth about $85,000 was mined and milled.

The length of Gold hill is about 3000 ft. Directly south of the Big Four, the Jumping Jack company cuts through with the eastern end of its claim into Gold hill. It was from the second level of the Jumping Jack workings, in September, 1911, that Mushett and Wittenberg, the present operators of the Big Pine, cut through to the south and east, cross-cutting the mineralized schist-zone. This zone has been proved from the Big Four to extend, following the line of the hill, for over 2000 ft. south, and from 50 to over 100 ft. in width, with a developed depth of over 200 ft. vertical.

The Big Pine claim, for over 1000 ft. takes in the schist-belt. About 350 ft. from the north end-line of the Big Pine is the Mushett and Wittenberg vertical shaft, sunk to 200 ft. Between the working-shaft and the northern limits of the claim, the ore found in the schist is being mined by glory-hole methods, being caved from the sides and ends of the opening in benches, dropped to the 200-ft. level into chutes, from there trammed to the shaft, and then raised to the surface. During the past year the present glory-hole has been worked, and its dimensions now show ore for 310 ft. north from the shaft, 50 ft. wide, and 200 ft. deep, equal to 240,000 tons of ore, from the surface to the 200-ft. level.

The mine and mill records show the following for July, 1915: The mill operated 86% of the month, lost time being due to installation of new crusher, trommel, etc. A total of 4409 tons passed through the tube-mill at the rate of 7.42 tons per hour, 178 tons per day. There was 12,000 tons broken, hoisted, and crushed during July. The tailing averaged 40c. per ton. The highest heads in the mill averaged $5.60, and the lowest averaged $2.20 per ton. The actual operating, mine and mill, cost during July,—including labor of installation, additional machinery, electric power, explosives, incidentals, etc., and the cost of development, south drift from 200-ft. level—shows an average of 46c. per ton hoisted and passed through the crusher. The work south from the main working-shaft, both from the 200-ft. level and by trenches on the surface, and glory-hole work on the southern end of the claim, proves that south from the shaft the known extent of the ore-zone to the 200-ft. level to be 400 ft. long, 75 ft. wide on the surface, but with an arbitrary average of 60 ft., equal to 370,000 tons.

The Reilly Fraction is a fractional claim adjoining the Big Pine to the south, and is owned by the Salsberry interests. Glory-hole operations in the schist produced about $100,000 worth of ore.

The Dexter Union Mines Co. has the largest holdings in the district, owning 16 patented claims. The Union Four claim, directly north and side-lining the Litigation Hill, has produced the most ore of any of their claims. At the present time Dexter Fourteen claim, lying north of the Big Four property, and covering the northern slope of Gold hill, is making a good production, the surface of the hill containing considerable placer gold, with deep placer workings in the main Manhattan gulch, across which the claim extends.

The Wall and Blaker properties are situated near the summit of the range on which the Manhattan district lies, south and east from the centre of the district and about two miles from Manhattan gulch. These properties during the past year have attracted considerable attention, owing to the large orebodies found there. The deposits seem to be mostly of a blanket nature following the contour of the hillsides, but further prospecting may prove the continuity of the ore in depth. Strong granite intrusions show directly west and south of the lodes. The Wall properties are being operated by Omar Maris and H. Z. Peters under bond and lease.

West from Gold hill is the Union Nine claim of the Manhattan Dexter Mining Co. This claim contains one of the strongest veins in the district. It was one of the first properties to be operated after the discovery of the Manhattan. About $500,000 is the known production by lessees of the company. On both ends of the claim the orebodies have proved to be large. In the Plamenaz lease they have been opened on the south end to a depth of over 400 ft.; on the north end, in the Briggs-Evans lease, to a depth of 240 ft. The mineralization in the Union Nine property is along a fault-plane, with oreshoots due in part to the intersection of the main fault by minor faults.

Directly adjoining Union Nine northward is the Little Grey claim, now under development by the Nevada Mining & Development Co. A depth of over 300 ft. has been reached in this property, and an orebody developed from that point, for a length of 160 ft. This is a continuation of the vein worked by Briggs and Evans in the early days of Manhattan, their lease-block being only 80 ft. south of the Little Grey working-shaft.

Among the mills of the district is the Associated mill, a custom-plant, close to the White Caps and Consolidated properties. This mill is equipped with an automatic sampler, 10 stamps, amalgamating-plates, tube-mill, complete cyanide-plant, and refinery.

On the Union Four claim of the Dexter-Union Mines Co. a 10-stamp custom-mill with straight amalgamation is being operated by Whitman & Kane.

The Manhattan Milling & Ore Purchasing Co. owns a 10-stamp mill, sampler, tube-mill, and cyanide-plant situated on the Wolftone claim close to the Little Grey.

The largest mill at Manhattan is the War Eagle. It has 20 stamps, 2 tube-mills, amalgamating-plates, and complete cyanide-plant. This mill is situated on the Mustang property, a low hill directly opposite the Little Grey and Dexter properties, but with Manhattan gulch between them.

The Round Lake Mine

By C. P. BOWIE

The Round Lake mine is situated in Plumas county, California, about 9 miles by wagon-road from Blairsden, a station on the Western Pacific railroad in the Mohawk valley. The mine and mill are at an elevation of about 6500 ft. above sea-level, in the Plumas National Forest, and are most picturesquely situated on a mountain-side immediately above a small body of water about a quarter of a mile wide and almost circular in shape, known as Round lake, from which the property derives its name.

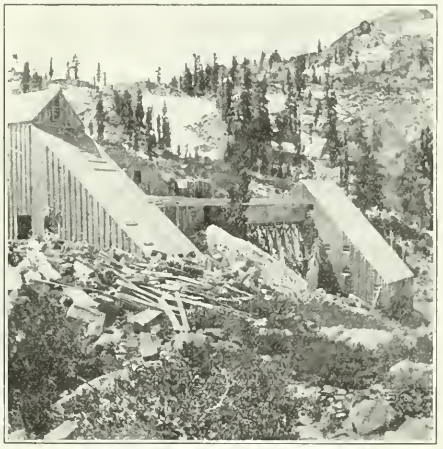
The outcrop of the vein, where it was discovered many years ago, was at the very water's edge and its strike and dip to all appearances carried it directly across the lake, although no sign of the vein has ever been found on the opposite bank. For this reason the prospect remained as such for a generation or more; locator after locator complied with the assessment law for a season or two and then allowed his rights to lapse, since the drainage of the lake presented difficulties and entailed an expense too great to warrant a venture, with no better outlook for reimbursement than that the ore might persist in depth.

It was not until the year 1911 that the present owners, M. H. Miller, who now personally superintends the operation of the mine and mill, in conjunction with W. P. Hammon, of San Francisco, and the Downer brothers, of Goldfield, took definite steps toward development. They, however, have made no attempt to drain the lake, but in lieu thereof started an incline on the hillside about 300 ft. above the outcrop. They cut the vein a short distance beneath the surface and have since worked only that portion of it lying above the water. The total depth of the incline is 350 ft., descending at an angle of about 45°. As a matter of fact, the bottom of the shaft is 60 ft. below the surface of the lake; however, no ore is at present being extracted from that depth. The incline has two compartments, a skip-way and a man-way, and is carefully and neatly timbered with stulls and lagging shaped from silver and white pine, respectively, which abound in the vicinity.

The surface improvements consist of a hoist-house, containing besides the head-frame and hoisting-engine, a blacksmith-shop and an ore-bin, into which the skip dumps automatically. The power for raising the skip is provided by an 18-hp. Western gasoline engine, which Mr. Miller reports as giving excellent satisfaction. There is also a mill, connected with the hoist-house by a covered runway about 100 ft. long. The mill is of sufficient size to admit of 10 stamps and the necessary adjuncts, but up to the present time only 5 stamps have been installed. The ore which is trammed by car from the bin at the collar of the shaft, is dumped onto grizzlies through which the fine passes direct to the bin that feeds the stamps, the larger pieces of ore being hand-shoveled into a crusher.

From the stamps the pulp passes through a 40-mesh screen over the usual copper plates, where the gold is arrested. The tailing, of which there is already an accumulation of 1000 tons, is at present being allowed to run directly into the lake; it being the plan later on, if satisfactory arrangements can be made with the Forest Service, to drain the lake, which, from soundings, seems to have a maximum depth of not over 60 ft., and recover the tailing, should circumstances warrant. The mill has a capacity of about 16 tons per day. Power is furnished by a Doak gasoline engine and the necessary water is pumped from the lake.

The vein has a width of from 6 to 10 ft. and strikes



THE ROUND LAKE MINE AND MILL.

northwest. The dip is east and varies from 15 to 40°. The vein-matter consists of white quartz, which is brittle and easily milled, and which in depth carries a considerable proportion of iron sulphides. Both the foot and hanging walls are of the same material, being composed of an igneous rock rich in feldspar, augite, and hornblende, so that it can be labeled a gabbro. The gold in the vein averages from $16 to $28 per ton and is fairly distributed across the entire width. This obviates the necessity for sorting the ore or in any other way handling waste; all the rock broken in the stopes is hoisted direct to the surface and milled.

Power may cost one company less per hour and yet the cost per ton be greater. An instance is given where a plant was generating electric power for 1 cent per kilowatt-hour and the cost of power per ton was 45 cents. An adjoining mine produced power for 1.25c. per kw.-hour and yet the cost per ton was only 25c. Investigation showed that the cheap-power company was wasting $80,000 yearly through imperfect and superfluous pumps and machinery.

The Balboa air-compressing plant, Panama Canal, produced 151,915,500 cu. ft. of free air compressed to 105-lb. pressure in June. The Gatun hydro-electric plant yielded 2,464,280-kw. hours.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting

The principal sheet-ground orebodies at Joplin, Missouri, lie at an average depth of 180 ft. in chert.

Cyanidation of tailing from the primary veins in the slate of the French Gulch and Deadwood districts of Shasta county, California, has not been successful. Some slate is mined with the ore, and owing probably to premature precipitation of the gold from solution by carbon in the slate, cyanide treatment is not practicable.

Free or loosely combined lime is generally considered to be the primary cause of unsoundness in portland cement. On hydration, free lime, according to fineness, hydrates as crystalline or amorphous calcium hydroxide, which disrupts cements. High-pressure steam is used to test samples of cement blocks for this weakness.

To meet the requirements of individual drive for machinery of various kinds, the electric motor must not only be compact, but must permit of being mounted in any position, while the windings and commutator must be partly or wholly protected from external injury. The motor must also be capable of standing sudden and heavy overloads.

Jade from New Zealand is the mineral nephrite. The Maoris called it *pounamu*. It is usually found as boulders in the glacial debris and from the boulders all the jade, or greenstone, ornaments have been made. The largest boulder, weighing five tons, was sent to Germany. The price averages 30 cents per pound and the average amount exported is 18,000 lb. The Chinese are profound connoisseurs in jade, but prefer that from Tibet.

Fifty stamps, 10 five-foot grinding-pans, and three 18 ft. by 4½-ft. tube-mills at the Sons of Gwalia mine, Western Australia, crush nearly 14,000 tons of ore per month. The average stamp-duty is 10 to 12 tons per day through 6 or 8-mesh screens. Of the tube-mill product 90% passes 150-mesh. The pans receive a pulp containing 40% on 60-mesh, and discharge 50% through 150-mesh. The Freeman selective pipe-discharge is fitted to them. The muller revolves at 60 r.p.m. The shoes and dies, 4½ in. thick, last 45 days.

Pneumatolysis is a process of mineral formation in which gases and vapors play an important part. When aqueous solutions aid in the result, the process is called pneumatohydatogenesis, which is a good expletive for a fishwife. Minerals formed by pneumatolysis occur chiefly around volcanoes. The exhalations are variously named: Fumaroles give out nitrogen, hydrogen, hydrochloric acid, hydrofluoric acid, and silicon fluoride. *Solfataras* exhale sulphur combinations. *Mofettes* are characterized by carbon dioxide; while boric acid vapors are termed *soffioni*. The intensity of pneumatolysis is shown by the filling of a lava crack with 3 ft. wide of specularite in 10 days—at Vesuvius in 1817.

Demons or gnomes are supposed to control the fortunes of miners. Malicious or amiable, they lead the miners to *borrasca* or *bonanza*. The belief in these imaginary beings still persists among the astrologers whose advertisements in the newspapers show all degrees of fraud and credulity. In the Middle Ages such belief was well-nigh universal. Indeed, the darkness of the mine, the sudden noises, the air-blasts, the explosive rocks that maim or kill, the sudden inexplicable changes from rich ore to waste rock, or the reverse, all tend to cause a belief in the supernatural. In the days of old these spirits were classified: *Goblins* were seen by men going to work or when attending cattle; *guteli* were good spirits; *trulli* were in the form of women or men and worked as domestic servants; *incubi* and *succubi* caused dreams.

Ore deposits are best represented by models, so constructed that the deposit is shown as a solid suspended from the mine openings; which are most easily represented in wood or copper wire. In default of models the following plans are absolutely necessary. 1. A ground plan, or projection of all the workings on a horizontal plane. 2. A separate ground plan of each level. 3. A longitudinal plan, that is, the projection of all the workings on a vertical plane parallel with the strike. 4. A stope plan or projection on the plane of the vein. 5. A series of transverse sections at right angles to the strike at various points. 6. Longitudinal sections parallel with the plane of the vein at different points. In the mines at Przibram horizontal plans are made at every 20 ft. and similar plans are made every 7 ft. in some Russian mines.

Gold pocket deposits in the Klamath mountains of northern California have been formed by a combination of favorable conditions, according to Henry G. Ferguson. The process of pocket formation seems to have been as follows: Gold, released from the original position in the pyrite of the low-grade manganiferous quartz veins, is taken into solution by nascent chlorine, formed by the action of sulphuric acid on a chloride with a manganese peroxide present as oxidizing agent. The peculiar conditions of the slate and meta-andesite contact have controlled the flow of these waters, which, unable to penetrate to any extent through the gouge-like slates, necessarily follow the slate-contact, particularly along the slate re-entrants. It is along this contact that the precipitating agencies, carbonaceous matter, pyrite and arseno-pyrite, are effective. The calcite neutralizes the gold-bearing solutions before they can proceed far from the source, and prevents continued migration downwards. Long erosion to the level of the Sherwood peneplain and below it in the stream valleys, has afforded an excellent opportunity for gradual deposition of the gold in these pockets.

The First-Aid and Mine-Rescue Contests at the Exposition

The week ended September 25 was 'Miners' Week' at the Panama-Pacific Exposition. The most interesting events were the first-aid and mine-rescue contests, held on three days. Complete arrangements were made for them, and the meet is considered to have been the most successful ever held in the United States. There were no disputes, all being satisfied with the decisions. It was the first time where coal and metal miners met, and it is interesting to know that, although the latter have not had more than 25% of the training of the coal men, the metal teams won the most of the contests. A year ago there was not a first-aid team in California, yet 10 separate California mines sent teams, and they did well.

As interesting as the contests were the five coal-dust explosions, the first made in this State. Four were on Pittsburg coal dust, crushed to from 100 to 200-mesh; and the fifth on Washington coal. For these demonstrations a 72-in. diameter fir-stave pipe 110 ft. long was constructed to act as an explosion-gallery. It was designed to stand a pressure of 25 lb., the pressure resulting from the explosions being from 12 to 15 lb., gradually diminishing to a low pressure at the open end. From 75 to 100 lb. of coal-dust was sprinkled in the gallery, as it occurs in a mine, and 1¼ lb. of 3F black blasting-powder was fired from a cannon into the gallery, representing a windy shot. The flame of a charge of this powder is long, hot, and of considerable duration, and gives sufficient heat to fire the dust and start an explosion extending through the gallery. The flame, as shown in the accompanying picture, is 50 ft. long. Immediately after a team of five men arrived in the auto rescue-truck and entered the 'mine' wearing oxygen-breathing apparatus, and returned with a supposed victim. Resuscitation methods were shown outside.

From 18 states came 26 first-aid and 15 mine-rescue teams. The following teams participated: Alaska Treadwell, Alaska; Anaconda Copper, Montana; Argonaut, California; Black Oak, California; Calumet & Arizona, Arizona; Carbon Hill Coal, Washington; Champion (North Star), California; Empire, California; Folsom Morris Coal, Oklahoma, representing that State, also Arkansas, Iowa, Kansas, Missouri, and Texas; Goldfield Consolidated, Nevada; Homestake, South Dakota; Kennedy, California; Louisville Coal, West Virginia; Mammoth Copper, California; Nevada Consolidated, Nevada; North Star, California; Pacific Coast Coal, Washington; Pennsylvania Anthracite region; Plymouth, California; Ray Consoli-

TOP: COAL-MINE EXPLOSION. BOTTOM: RESCUE CORPS EMERGING FROM MINE WITH VICTIM.

dated, Arizona; Roslyn Fuel, Washington; Superior Coal, Wyoming; Tonopah Mine Operators' Association, Nevada; United States Fuel, Utah; and Utah Fuel, Utah. Medals, cups, and other prizes were donated by the California Metal Producers Association and many manufacturing firms interested in mining.

Results were as follows:

First-aid, only California teams:

Event.	Problem.	Mammoth.	Argonaut.	Empire.	Plymouth.	North Star.	Kennedy.	South Eureka.	North Star.	Black Oak.
5-man	1	98	87	90	87	91	74	87	72	87
5-man	2	84	93	79	91	74	95	86	92	79
5-man	6	98	88	96	84	97	93	86	91	83
5-man	11	94	94	96	94	94	93	92	94	93
Total points		374	362	361	356	356	355	351	349	342
Percentages		93½	90½	90¼	89	89	88¾	87¾	87¼	85½
Result		1	2	3	4	4	5	6	7	8

The problems were as follows:

(1) Four fingers of left hand severely crushed, with lacerated wound of palm of hand which is bleeding profusely; treat and carry patient 20 ft. by shoulder lift.

(2) A car has run over patient's left foot, cutting it off in front of ankle joint; severe bleeding; treat and carry patient 30 ft. by two-hand seat.

(6) Punctured wound of palm of right hand (bright red blood); small cut on calf of left leg with slight bleeding; left ankle sprained; treat case.

(11) Broken back with simple fracture of right forearm; treat and prepare for transportation.

For the first-aid inter-state elimination contest there were 22 entrants. The finals were as follows:

Event.	Problem.	Homestake.	Nevada Consol.	Bunsen Coal.	Ray Consolidated.	Alaska Treadwell.	Utah Fuel.	Pacific Coast Coal.	Louisville Coal.
1-man	5	100	100	89	93	98	95	94	100
2-man	3	100	100	95	95	96	86	93	94
3-man	3	98	98	100	93	96	100	95	95

5-man	6	99	100	100	100	95	93	96	100
Total points		495	493	480	478	478	474	474	472
Percentages		99	98.6	96	95.6	95.6	94.8	94.8	94.4
Result after working off ties		1	2	3	4	5	6	7	8

The Anaconda, Superior, Kennedy, and Folsom Morris teams were 9, 10, 11, and 12, with 94.4, 93.6, 88.8, and 87.8% respectively.

The problems were as follows:

(5) Man found on charged electric wire unconscious, burned on right hand and forearm; remove and treat conditions.

(3) Compound fracture of the left leg below the knee, involving both bones; prepare patient to stand transportation.

(3) Burns of head, face, neck, arms, and hands; profound shock; treat.

(7) Man overcome by after-damp, requiring immediate removal, burns on hands, arms, neck, and face; carry patient 10 ft. on an improvised litter; two of team at that time should be supposedly overcome by gas, remainder of team carry patient without a litter for 20 ft. to fresh air and treat the case.

(6) Patient found on his back across live electric wire, unconscious; rescue and give artificial respiration for one minute; then treat burns on the back and right upper arm, carry 30 ft. on any improvised stretcher except one made of poles and coats.

This, the first California first-aid meet, and the third National joint field-meet for miners was held under the auspices of the California Metal Producers Association (also financed by this organization), the National Safety Council, the U. S. Bureau of Mines, and the Mines and Metallurgy Department of the Exposition. R. U. Patterson, chief of the American Red Cross was chairman of judging the first-aid, and James Bagley, inspector from Washington was in charge of the mine-rescue judging, with R. J. Kerr as chairman of recording. Others connected with the meet were Van H. Manning, director of the U. S. Bureau of Mines; G. S. Rice, chief mining engineer of the Bureau; J. W. Paul, chief rescue engineer at Pittsburg; W. D. Ryan, safety commissioner of the Bureau; E. Steidle, at 'The Mine' at the Exposition; J. C. Roberts, engineer in charge of the Rocky Mountain district, with mine-rescue car No. 2; H. M. Wolflin, engineer for the Bureau on the Pacific Coast; and H. M. Wilson, formerly with the Bureau.

The final inter-state mine-rescue contest resulted as follows:

The problem involved the following test:

Following an explosion, the crew finds a stopping across the drift or entry, canary dead; tear hole in stopping and rescue miner, who is found unable to walk. Do not carry miner over overcast, the air just before it being good.

Each crew walked 117 yd. in two minutes, remained in smoke-room for four minutes, with apparatus, were examined by a doctor, the captain explained the tests to ensure the safety of the men, the apparatus was judged, then the work proceeded.

Event.	Problem.	Utah Fuel.	Roslyn Fuel.	Goldfield Consol.	Homestake.	Anaconda.	North Star.	Calumet & Arizona.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

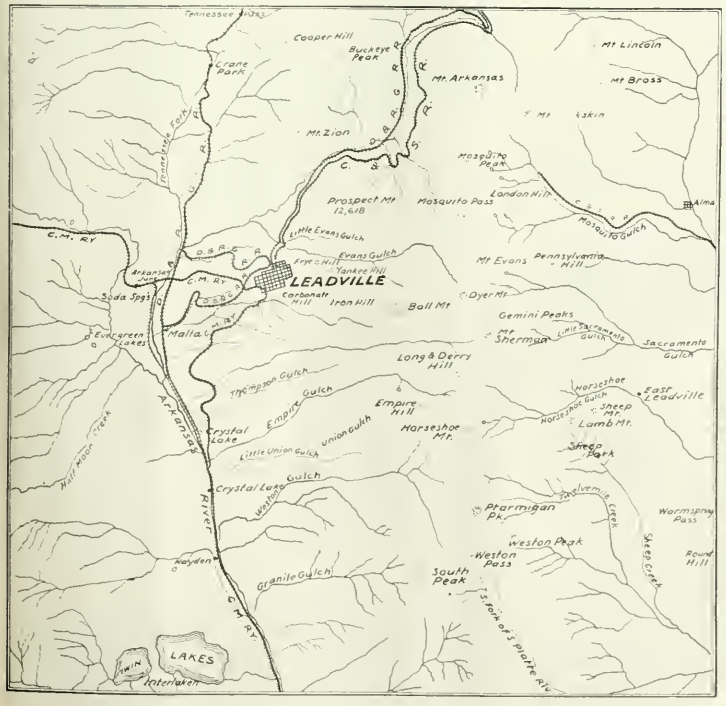
Extensive Exploration of Prospect Mountain Commenced. —Yak Tunnel to be Extended to Explore Lower Part of Mosquito Range.

Prospect mountain is the situation of another large enterprise to develop the extensive and little explored territory included in the area between Big Evans gulch and the Arkansas valley, lying at the extreme northeastern edge of the Leadville district. C. H. Weaver, F. G. Kahle, and H. A. Huttinger, of Toledo, Ohio, owners of the Buckeye zinc mine at Joplin, Missouri, have formed a company with W. B. Anderson, well known in Leadville and owner of the Anderson adit, for the purpose of continuing the work on this property. The company is completely financed as a closed corporation, with each of the above-mentioned men holding equal interests. Mr. Weaver is here in active charge of the undertaking.

The Anderson adit is situated on the northeast slope of Prospect mountain, about a mile above Birdseye, at an altitude of 10,800 ft. Mr. Anderson controls a large area there, extending from the portal of the adit over the ridge to the Big Evans side of the mountain. The opening is now 1000 ft. long, following a southeasterly direction toward Leadville, a course which is calculated to cut many of the large oreshoots that were found on this side in the valley, Silver Spoon, New Monarch, and other properties in the Big Evans territory. A number of other veins have been found from surface outcrops, and the new management expects to reach the first one within 60 days after work in the breast has been started.

The adit is one of the largest in this district, being 6 by 7½ ft. in the clear, with a 22-in. gauge track. A power-line is being erected from the Colorado Power Co.'s main near the Resurrection No. 2 in the Big Evans, directly over the ridge to the portal of the adit, a distance of about two miles. This work is being rushed, and is expected to be complete within a month. A telephone-line is being brought in to the property from Birdseye, and a road is under construction from the railroad siding near this point, over a mile of easy grade to the adit.

The adit will be equipped with modern electric machinery. The entire plant from the old Siwatch adit on Sugar Loaf, including 8000 ft. of heavy steel rails, 7 motors, 10 cars of 3½-ton capacity, air-compressors, and air pipe-line has been purchased by the new concern, and the work of moving the machinery to the Anderson adit is progressing rapidly. New surface buildings are being erected on the property, and extensive preparations are being made to put the adit in first-class working order for the winter. At the present time 20 men are employed on the preliminary work, and as soon as the machinery arrives on the ground the force will be increased. Installation of the machinery is expected to require two months. After that time the adit will be ready for extension, and three shifts will be occupied until the first large vein is cut. Men will start cross-cutting on the vein while the breast is pushed farther ahead.



THE LEADVILLE DISTRICT, COLORADO.

Prospect mountain and Mosquito range just now are attracting the interest of mining men throughout the State. With the Valley adit opening the formations of Prospect from the Leadville side, the Anderson adit coming in from the Birdseye slope, and the Yak tunnel pushing farther ahead into the foot of Mosquito range, it appears that this territory is to be the productive centre of the Leadville of the future.

The announcement of the Yak Mining, Milling & Tunnel Co., stating that the breast of the big bore will be advanced farther into the formations of lower Mosquito range,

has resulted in renewed interest in the large territory extending through the head of Big Evans gulch, Mosquito range, and Prospect mountain, where comparatively little deep mining has been done. The Yak company recently closed a large deal with the owners of the Aladdin group of claims in the Big Evans beyond the present breast of the Tunnel, as mentioned in the PRESS of September 18. The deal included an extension of 10 years on the lease which the company holds on the ground and provided a bond of $600,000 on the property to be paid within the time of the lease. The acquisition of this large tract of valuable land brought about the decision to advance the Tunnel into this ground.

Immense bodies of lead carbonate ore have been opened in the Vega property, which is part of the Aladdin group. These deposits have been worked through the Yak tunnel by means of the Diamond winze at the face of the adit. Extensive prospecting has been carried on in this ground, and the results obtained justify the advancement of the main Tunnel into the territory to a point where exploration of the ground will be greatly facilitated. The ore-shoots in this section dip away from the Tunnel to the northeast, and the future mining of the area will be at great depth. The orebodies uncovered at present are thought to be the continuation of the shoots mined in Breece hill to the southwest, and at much less depth. This ore-belt is now thought to be continuous from Breece hill through Mosquito range to the London mines in Park county.

The Yak tunnel is now a little over four miles long from the portal in California gulch through Carbonate hill, Iron hill, and Breece hill to the breast at the Diamond in Big Evans gulch. It practically traverses the entire district, and passes through the richest parts at a depth from 800 to 1400 ft. Many properties are operated through the Tunnel, and the total tonnage from the bore is the largest in the district. Gold, silver, lead, copper, and zinc ores, both oxide and sulphide, are mined by means of the Tunnel at the rate of 300 tons per day.

TORONTO, ONTARIO

SUMMARY OF OFFICIAL REPORT ON THE KOWKASH GOLDFIELD.—OPTION TAKEN ON DISCOVERY CLAIMS.—ZINC IN QUEBEC.

The assistant provincial geologist of Ontario, Percy Hopkins, who made a preliminary examination of the gold discovery at Kowkash, has forwarded his report to the provincial Bureau of Mines. The following is a résumé:

Kowkash station is 297 miles west of Cochrane on the National Transcontinental railway. The discovery is 9 miles northwest from Kowkash station, near Howard falls, on the Kawa-kash-kagama (Kowkash) river. The canoe route commences 1½ miles east of Kowkash station, and involves two short portages in a 20-mile trip. The country is of low relief, and consists of rocky hills up to 100 ft. or more in height, separated by large swamps, semi-muskegs, and sand and gravel areas. The rocky hills are covered with a dense growth of small timber and moss, and sometimes large loose boulders, which make prospecting somewhat difficult. E. W. King Dodds made his rich discovery on August 21, when walking over the rocky hill below Howard falls, which had been burned clean of moss and trees on the previous day. The news caused a rush of about 400 prospectors, and from 75 to 100 claims were staked within three weeks.

In the Kowkash area is a belt of Keewatin rocks 10 to 15 miles wide, extending from the north end of O'Sullivan (or Sesekenaga) lake in a southwest direction through Howard falls, and across the height of land at Redmond. The whole Keewatin area is worth prospecting for gold. For miles around this Keewatin belt are Laurentian granite and gneiss rocks. The Keewatin are largely massive fine-grained green chlorite and hornblende rocks, which are in places altered to schist. Some of the chlorite rock is altered diabase. Numerous exposures can be seen along the Kowkash river. Altered basalt showing the pillow or ellipsoidal structure are common, and with the basalts are small agglomerate areas. Cutting these greenstones are numerous white weathering quartz porphyry dikes up to 30 ft. or more in width. They contain numerous white quartz phenocrysts, the size of peas, in a gray to green fine-ground mass. The porphyry contains some quartz stringers, is schistose in places, and resembles the quartz-porphyry at Porcupine, Goodfish lake, and north of Schreiber. The main exposures seen extend for a mile east from Howard falls and around O'Sullivan's lake. An exposure on a large hill about two miles below Howard falls is a slate and conglomerate similar to the Timiskaming sediments in Porcupine, Kirkland Lake and Munro Township. The slate is cherty and the conglomerate pebbles consist of chert, quartz-porphyry, amygdaloidal basalt, and gneiss. Around the centre portage between Abamasagi and O'Sullivan lakes is a fine slate-like biotite and chlorite schist, which may be of sedimentary origin. At the last portage into O'Sullivan lake is an actinolite rock, below which are numerous massive serpentine exposures. A gabbro and diabase, probably the youngest rock in the area, occurs about 300 yd. north of the Dodds gold discovery. Dikes a foot thick also cut the basalt on the Dodds claim, the vein on which is ⅝ of a mile below Howard falls, and 800 ft. north of the river. The vein strikes 8° south of east and appears to dip 75 or 80° to the north, conforming in strike and dip with the country rock. The vein is somewhat lenticular, is up to 4 to 5 in. wide, and can be traced about 40 ft. ending in drift on either end. The quartz is glassy and free from sulphides. Specimen ore was seen in place over an area about 5 in. long and one inch wide, extending along the hanging-wall side of the vein. Similar and richer specimens were reported to have been taken from the 4 or 5 ft. adjacent to the above shoot. On the hanging-wall side of the vein is a rusty schist band 6 in. wide, heavily mineralized with fine pyrite. The wall rock is pillow lava (basalt), which is altered to schist in places. A mineralized quartz-porphyry dike occurs about a chain southeast of the discovery. The report concludes as follows: "The geological formation of the Kowkash district is somewhat similar to that of the Big Duck lake area north of Schreiber, 100 miles south, Goodfish lake, (Morissette Township) and Tisdale Township in the Porcupine gold area. Numerous small glassy quartz veins, some of which are mineralized with pyrite, occur over the whole area, the Dodds vein containing a very spectacular gold showing. This would suggest the advisability of a thorough prospecting of the Keewatin area."

The timber is mostly second growth, most of which has been recently burned. The trees consist of small spruce, poplar, Balm of Gilead, pine, birch, and cedar, some along the river attaining a diameter of two feet. There is some good agricultural land. Whitefish, pickerel, pike, suckers, and brook trout up to two feet long are plentiful in the Kowkash river. The Howard falls are formed by a ridge of chloritic hornblende-schist, through which the river cuts, making a narrow canyon-like gorge 14 chains long. This gorge is from 20 to 30 ft. deep, and the water descends in steps and slides varying from one to five feet. The falls are suitable for power purposes.

A Canadian-American syndicate, headed by John L. Orn, of Buffalo, and C. M. Forbes of Lanark, Ontario, has taken a working option on the three King Dodds claims at Kowkash. Work will be started as soon as possible. The price of the option is said to be a good one. Two payments have been made. About $10,000 is to be spent in development in the next four months.

An important discovery of zinc ore is reported to have been made by Dennis Callahan, a prospector of Haileybury, Ontario, near Burbridge lake in the upper Gatineau district, Quebec, about 70 miles north of Ottawa. John D. Macfarlane, mining engineer, has left Ottawa to investigate the reported find. He is familiar with the locality, and thinks that large deposits of zinc may occur there.

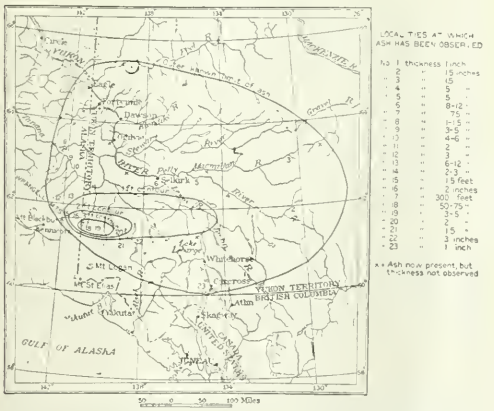
THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

The Development number of *The Alaska Daily Empire* at Juneau consists of 40 pages covering the activities of the Territory. The governor, J. F. A. Strong, contributes a page on resources and possibilities. Following this are illustrated write-ups of the commerce, Juneau (accompanied by a large photograph), banking institutions, Juneau gold belt, fisheries, scenery, power projects, mines on Douglas island, Prince of Wales island, Douglas, land laws, Prince William sound, hunting, sport, library at Juneau, agriculture, religion, and statistics.

In Professional Paper 95-D of the U. S. Geological Survey, Stephen R. Capps discusses an ancient volcanic eruption in the upper Yukon basin. A large area of Alaska and Yukon Territory is covered by a layer of volcanic ash. This ash lies beneath a thin coating of soil or silt, and in terms of geologic history the eruption is very recent, though antedating historic



MAP OF UPPER YUKON BASIN, ALASKA AND YUKON TERRITORY, SHOWING DISTRIBUTION OF VOLCANIC ASH.

record in this part of the world. Several geologists have investigated the ash deposit. It usually appears along the cut banks of rivers, is persistent, and in places is continuously exposed for miles. The ash bears a close relation to the present surface of the country. The White Pass and Yukon route to the navigable waters of the Yukon basin follows the ash-covered area. Volcanoes in the Mt. Wrangell group were thought to be the source of the ash, but it is now considered that the material was ejected from some crater near the northern border of the St. Elias mountains, near the international boundary, probably from a vent four miles north-northeast of Mt. Natazhat. The wind at the time was blowing from the west and south, and about 140,000 square miles was covered with ash.

JUNEAU

During August the Alaska Mexican mine produced $33,282 from 19,075 tons of ore. The estimated net profit, after deducting $3515 for construction, was $4957.——The Alaska Treadwell yielded $153,668 from 79,650 tons. The profit was $28,933, $22,308 being the cost of construction.

ARIZONA

COCHISE COUNTY

The Shattuck-Arizona company reports that development during August totaled 1844 ft., nearly all of which was in good copper ore.

GILA COUNTY

The Laurel Canyon Mining Co., operating 25 miles south of Fort Thomas, is planning a 300-ton concentrating plant to treat lead ore. Present shipments are 12 tons of concentrate daily. L. E. Wightman is a director.

GREENLEE COUNTY

The general managers of the Arizona, Detroit, and Shannon copper companies, N. Carmichael, M. McLean, and J. W. Bennie respectively, have addressed a communication to their employees who are on strike, dealing with the situation. Committees of the men must be appointed to meet the companies, but recognition of the Western Federation of Miners must not be a demand of the men.

Later news from Clifton shows that on the advice of C. F. Moyer, president of the Western Federation of Miners, the Morenci strikers waived their demand for recognition of the Federation; Clifton and Metcalf men did likewise. The wages are said to be lower than any copper centres of Arizona, but the labor is said to be less efficient than at the other places, 85% being Mexicans. Wages paid to miners in three districts compare as follows:

Price of copper	Globe Cents per hour	Clifton-Morenci Cents per hour
14 cents per pound	47	*32½
15 " " "	*47	33½
16 " " "	49	34½
17 " " "	50	35½
18 " " "	52	36½
19 " " "	†53	†37½

*Minimum. †Maximum.

CALIFORNIA

Oil production of this State in August totaled 7,680,047 bbl., a small decrease compared with July. Shipments from the fields amounted to 8,077,586 bbl., a large increase over the previous month, and the first month since July 1914 that the total was over 8,000,000 bbl. The Independent Oil Producers Agency reports that 6153 wells were producing oil in August; the Standard Oil Co. gives 6501 wells.

The iron ores of California and possibilities of smelting is discussed by Charles Colcock Jones of Los Angeles in Bulletin 104 of the A. I. M. E. There is no production of pig-iron west of Pueblo, Colorado, and from Canada to Mexico, the area comprising the inter-Mountain and Pacific Coast region, excepting a small quantity made by an electric smelter at Heroult, Shasta county, California. The author estimates that there is 200,000,000 tons of high-grade iron ore, and twice that amount of probable ore in southern California. The three most practically available deposits are at Eagle mountain, Cave canyon, and Providence mountain, in San Bernardino county, containing about 125,000,000 tons. The ores are 4 to 10% richer than the standard Lake Superior iron ores, and are suitable for reduction by smelting. Consumption of pig-iron on the Pacific coast is about 100,000 tons per year, and steel an additional 823,000 tons. The cost of mining these deposits would be low, esti-

mated at 85c. per ton. Transport and mining charges would be about $3.19 per ton of pig iron, Bessemer grade, against $8.05 for Lake Superior ores. Alaskan, Washington, or Utah coke could be used in smelting iron ore in California. Ample deposits of limestone are available to railroads entering Los Angeles. The principal iron deposits of southern California are of the contact-replacement type, formed at or near the contact of an intrusive igneous mass with sedimentary strata, usually limestones.

AMADOR COUNTY

It is reported that the Original Amador company is preparing plans to double the capacity of its mill at Amador City.

At the Keystone mine 80 men are employed under C. R. Downs. Forty stamps are crushing ore.——Near Pine Grove a rich shoot has been cut in the Pine Grove property. R. Robinson is in charge.

BUTTE COUNTY

With 25 men, J. Reese of Salt Lake City is re-opening the Gold Bank mine at Forbestown. It has been closed for some years.

The Undine gravel mine, 15 miles from Chico on Butte creek, has been acquired by D. S. Nesmith of Boston and San Diego. ——Oroville people have leased the Butterfly mine in Morris ravine. A new adit will be driven.

ELDORADO COUNTY

The oldest five-stamp mill in the State continues its work at the Morey mine, northwest of Grizzly Flats. It has been running since 1868, driven by water power.——The old Mt. Pleasant mine near the same place is being unwatered.——Development and mining of the limestone deposits southeast of Placerville is probable. The Southern Pacific company is surveying a line in the vicinity. The deposits are bonded to the California Portland Cement Co.

The old Mount Pleasant mine near Grizzly Flat is being unwatered. It is 1100 ft. deep, but little work has been done below 600 feet.

NEVADA COUNTY

At Nevada City a petition has been prepared asking John E. Raker, member of Congress, to use his influence in getting about $150,000 to construct a dam on the Bear river to enable hydraulicking to be resumed at Dutch Flat, You Bet, Lowell, Quaker, and Liberty hills. This is expected to add materially to the gold output of the region.

Litigation between the Empire and Golden Center companies at Grass Valley has been avoided by an agreement whereby the latter can work all veins apexing west of Auburn street, between Main street and the south boundary of the city; and no limits on the west boundary. The Empire can work all veins that apex east of Auburn street. Some cash is included in the arrangement.

The 'specimen boss' at the Empire mine, who stole ore worth over $40,000, was sentenced to four years' imprisonment.

PLACER COUNTY

The Gray Eagle Canyon placer claims have been sold by W. F. Russell of Boston to C. L. Austin and A. Fitch of Utah, for $14,800. The property is between Auburn and Forest Hill.—— The J. L. Gould property at Dutch Flat is being surveyed. A 2200-ft. adit has been driven.

PLUMAS COUNTY

The Engels Copper Co. is surveying for a narrow-gauge railway from the mine down Indian valley and Indian Creek canyon to the Western Pacific line at Keddie. The Great Western company's power-line has been connected with the property.

The U. S. Exploration Co. is to re-open the Robinson mine at Granite Basin, near the Butte County line, in charge of C. N. Miller. The old 20 stamps are to be replaced by a Sears-Smith mill. Bunk-houses are being built. From four to six miles of road will be constructed in the spring. The Butte and Plumas railway may resume operations as a result of this new work.

SIERRA COUNTY

The Tightner mine continues to supply its mill with good ore.—The Croesus 15-stamp mill is working at the Plumbago gold mine.——Development continues at the Eldorado, Gold King, Golden Fraction, Twenty-One, and other mines.

TRINITY COUNTY

Ten miles east of Weaverville, D. B. Fields and Meckle Bros. have discovered an extensive lode on Mt. Bally.

COLORADO

The Colorado Fuel & Iron Co. reports as follows for its past financial year, compared with other periods:

	1915	1914	1913
Coal mined, tons	2,329,069	2,428,992	4,091,667
Coke made, tons	520,261	535,274	784,627
Iron ore mined, tons	441,026	614,039	853,878
Limestone mined, tons	344,033	376,226	485,756
Pig iron made, tons	286,661	268,883	.....
Finished iron and steel, tons	324,600	352,929	458,521

Most of the iron ore comes from New Mexico.

DOLORES COUNTY

Salt Lake City men recently acquired the Argentine and Blackhawk mines at Rico, and among the extensive development proposed is an adit to cut the known veins at depth. These mines have a long and interesting history.

GILPIN COUNTY

The Pittsburg mine continues to produce rich gold-silver-copper ore, which is treated at the Iron City mill.——A 10-stamp mill is to be erected at the Bates mine at Mountain City by W. S. Smith. This plant will be moved from the Winnebago mine. Concentrate from ore mined from the Bates was settled for at 9.75 oz. gold, 9.25 oz. silver, and 12% lead for the first-class material.——The Ingalls Leasing Co. has made a test shipment to the U. P. R. mill.——Miners have been visiting the Nederland tungsten mines with a view to leasing.

LAKE COUNTY (LEADVILLE)

Water in the Penrose shaft is down 570 ft. At 600 ft. is the old station on which was the pumping plant of the Home Mining Co.——An electric pump has been installed in the Monarch shaft, which has been sunk from 575 to 725 ft. this summer. This mine produces 800 tons of gold, silver, lead, and zinc ores per month, on company and lessees' account.—— Zinc tailing from the old Adams mill in Strayhorse gulch is being treated at the Leadville district mill, where flotation is used.——The Star mine is sending 100 tons of iron-manganese ore per day to the steel works at Pueblo.

SAN JUAN COUNTY

The region contiguous to Silverton continues to be busy and increase the quantity of ore shipped. Prospectors are making use of the season available. Encouraging results are reported from the Sunnyside, Ledge, Columbus, and Gold King mines and mills.

IDAHO

BOISE COUNTY

(Special Correspondence.)—After being quiet for many years gold mining in Boise basin is showing renewed activity. The Diana Mines Co. was incorporated at Boise last week with a capital of $2,000,000. Nearly all of the stock is in the name of Frank T. Day of Colorado. Buffalo and Boise people are also interested, J. A. McCubbin at the latter place. A property near Placerville is to be developed and should assist work generally.

Boise, September 24.

SHOSHONE COUNTY (COEUR D'ALENE)

September dividends of Coeur d'Alene companies totaled $673,736. The Interstate-Callahan and Stewart disbursements were for the quarter.

According to Stanly A. Easton, manager of the Bunker Hill & Sullivan, the company is to erect a smelter near Kellogg, if easements are obtainable from land owners that will secure immunity from damage suits for fume from the plant. Custom ores may be treated also. So much ore is being carried on the Murray branch of the O.-W. R. & N. line that the service is to be extended.

The Hecla Mining Co. of Burke has distributed 7c. per share, or $70,000, for September. This year's total is $325,000, and $2,315,000 to date.——At the Guelph property a shaft is being sunk to 700 ft. depth. A hoist and compressor is being installed.——The Coeur d'Alene Development Co. has secured an option on eight claims of the Wonder of Pine Creek company in the Pine Creek district, for $10,000. The property is three miles west of the Bunker Hill & Sullivan. About 10,000 ft. of diamond-drilling is to be done.

MISSOURI

Jasper County

Several new mills were started in the Joplin district last week. At the Gartung tailing plant on the Emma Gordon land at Miami, Oklahoma, there are no cleaner jigs; two 'roughers' are used instead and no recovery of concentrate is made from either rougher, all 'chats' being ground and passed over a series of tables.

MONTANA

Silverbow County

The vein cut at 2500 ft. in the Davis-Daly has been opened for 60 ft., showing 10 to 12 ft. of 8% copper ore. In the middle is 3 ft. of copper glance. Stoping is to be commenced.

NEVADA

In Bulletin 620-D of the U. S. Geological Survey 'Some Cinnabar Deposits in Western Nevada' are discussed by Adolph Knopf. A belt of these deposits is situated in the heart of the Pilot mountains, eight miles direct south of east of Mina, Esmeralda county. The average altitude is 7300 ft., 2700 ft. above Mina, the supply point. The ore was discovered in June 1913 by T. Pepper and C. Keough. Not much development has been done so far. Six miles east of Beatty, Nye county, is the Fluorine quicksilver district. After a lot of extravagant estimates were published about the area little has been done. An adit was put in 1100 ft. to open $22,000,000 of ore, but none was found.

Clark County

(Special Correspondence.)—The Big Casino Mining Co., owned by Philadelphia people, consists of a large copper-gold area four miles east of Searchlight. The group is situated within 10 miles of the Colorado river, and almost 3000 ft. above it in a low range of mountains that have been capped by a lava-flow. The main shaft is down 400 ft. The deepest workings show considerable chalcopyrite with galena and some zinc-blende. A small experimental concentrating-plant has been erected. Results show a high-grade gold concentrate, also high in copper, lead, and zinc. The zone in which the ore occurs has a width of 250 ft. It consists of an altered andesite, the enclosing country rock being granite-porphyry.

The president of the Big Casino Mining Co., J. F. B. Pascoe, recently made an examination of its property with a view of starting development on a much larger scale than heretofore.

The Colorado-Nevada company's new 80-ton cyanide-plant at El Dorado canyon is working continuously under the management of G. A. Duncan of Denver.

The Duplex Mining Co. has lately shipped several cars of first-class ore to smelters at Salt Lake City, but is now closing down with a view of installing its mill before further development.

The W. Black lease at the Quartette mine is shipping regularly to Utah smelters, and also treating considerable free gold ore at the Cyrus Noble mill. The Quartette tailing-dump will soon have a $30,000 cyanide-plant erected thereon for its treatment. It is owned by B. F. Miller, Jr.

Searchlight, September 17.

Esmeralda County

The final report of the Goldfield Consolidated for August states that the net profit from 32,100 tons of ore was $106,624. Costs amounted to $4.86 per ton. Development totaled 3291 ft. at a cost of $5.06 per foot; this work revealed nothing of great importance. Lessees produced 992 tons of ore worth $23,085, of which the company received $11,795, less transport and treatment charges.

At the Jumbo Extension No. 2 shaft is down 500 ft., on its way to the 1017-ft. level. Ventilation will be improved when it connects with the 790 and 873-ft. levels. Ore shipments amount to 80 tons per day, averaging $45 per ton.

The new head-frame at the Florence is complete. Development continues on the usual plan. About 300 tons of ore was extracted in September, mostly from stopes on the new vein above 250 feet.

Humboldt County

(Special Correspondence.)—The De Lorme interests in the Lincoln Hill Milling & Mining Co. have been purchased by G. S. Johnson, who has been elected president. The property is equipped with an air-compressor and machine-drills, and a two-stamp Hendy mill. It is producing about $5000 gold per month, the ore averaging $150 per ton. Extensive development is proposed.——The Friedman adit of the Rochester Mines Co. is in 1000 ft., and should soon reach the first vein at a depth of about 1100 ft., 600 ft. below the deepest workings. Two winzes are being sunk from the 300-ft. level on a vein averaging 5 ft. thick assaying $25 per ton, of which $9 to $12 is gold. The mill is treating 120 tons a day of $15 ore.——The mill building for the Nevada Packard cyanide-plant is completed, and the machinery is being installed. The plant will be finished early in November, and will treat 75 tons per day.

Rochester, September 25.

At the Jack mine, 24 miles northeast of Golconda, ore containing 18% molybdenum has been opened. A 100-ft. incline shaft has been sunk, and 400 ft. of driving.

Lincoln County

The new mill at the Yuba Leasing & Development Co. at Pioche is ready for work, being erected in 60 days. From a 500-ton bin the ore is crushed by a 9 by 15-in. jaw crusher, reduced wet in a Marcy ball-mill, concentrated on Wilfley tables (concentrate is shipped to smelters), and then treated by cyanide in the Trent apparatus. The plant is driven by a 100-hp. gasoline engine.

Mineral County

The Rand district continues to excite attention, and incidentally some booming.——A recent shipment from the Golden Pen averaged $1000 per ton for the 45 tons. Over 300 tons of similar ore has been opened. No. 2 stope shows 18 in. of over $500 ore. A deal is pending for the sale of this mine.——The Queen Regent Merger has erected a hoist. Two shifts are sinking to 500 ft. No. 2 shaft has produced 300 tons of shipping ore, and has opened good milling ore. Other properties are developing well. The main country rock is rhyolite.

Nye County

During the week ended September 25 five mines at Tonopah and lessees produced 9629 tons of ore valued at $199,282. The Belmont, Extension, and Tonopah companies shipped a total of $210,000 of silver. There is nothing of importance to report from the mines and mills. The smaller properties continue their exploration, the Umatilla-Tonopah diamond-drill being down 1600 feet.

Sluicing at Round Mountain ceased on September 1; it will be resumed next March. Bedrock and sluice-boxes are now being cleaned up. The gravel averaged $2 per cu. yd. At 700 ft. in the mine a cross-cut has passed through 5 ft. of $50 ore. This is the Los Gazabo vein.

OKLAHOMA

Ottawa County

It is again proposed to erect a storehouse in the Miami zinc district to store concentrate. In discussing the project a prominent mining man said,

"An accumulation of concentrate in regular warehouses would necessitate future sales and take from the market much of the sharp fluctuation produced by solely cash sales. The future selling of accumulated material of standard grades would make it possible for anyone, anywhere, to purchase such product quickly and cheaply through brokerage firms instead of as at present or by representatives. At the present time prices can drop to a low figure with nothing to arrest the decline, but under the warehouse system a low-water mark could be established below which the price of ore could not drop. The warehouse receipt would also be the best possible collateral security and the holder would be able to borrow call money at any time at a reasonable rate of interest, thus being able to meet operating expenses and be able to sell to the best advantage instead of glutting an already weak market."

TEXAS

El Paso County

(Special Correspondence.)—Mining operations in Mexico must be greater than for several months past considering the large increase in the exports of ores and bullion from that country to the United States during September. Besides the shipments that were made through El Paso, considerable imports came through Eagle Pass and other border ports of entry. Receipts for the month through El Paso include 16,000 bars of lead that were imported by the American Smelting & Refining Co., consigned to its refinery at Perth Amboy, New Jersey; 13 cars of miscellaneous ores, imported by the Kansas City Consolidated Smelting & Refining Co.; 30,000 bars of lead and three cars of bullion, imported by the Balbach Smelting & Refining Co.; 27 cars of zinc ore, imported by the United States Zinc Co. of Sands Springs, Oklahoma, and four cars of zinc ore, imported by the National Zinc Co. of Bartlesville, Oklahoma.

Many of the American and Mexican mining companies in the different districts of the interior of Chihuahua and Durango have resumed operations after a long period of inactivity. The situation in the mining districts of the States of Jalisco, Guanajuato, and Zacatecas is much improved compared with that of a month or so ago, according to reports received here.

El Paso, September 25.

UTAH

Salt Lake County

At a meeting of the Wasatch Mines Co. held at Salt Lake City last week it was decided to erect an aerial tramway from the Little Cottonwood district to the terminus of the Salt Lake & Alta railroad. A 4000-ft. drainage-adit, costing $60,000, will be driven. Other operating companies were at the meeting, and it is probable that a joint company will be formed to look after these projects. C. H. Cowie, C. H. Gibbs, and J. E. Beveridge are connected with the Wasatch company. The two schemes will cost $200,000. The tram will have a capacity of 500 tons per 24 hours, and will begin near the portal of the proposed drainage-adit near the South Hecla property, and will traverse the Wasatch Mines ground to the portal of the Howland, or what is also known as the Columbus Extension adit. Near that point loading-stations will be built, and ore at present being transported by the Michigan-Utah aerial tram will be automatically loaded on the new tram which will extend from that point on down to Wasatch, the terminus of the Salt Lake & Alta railroad.

High-grade copper ore has been cut in the Albion mine where the fatality occurred two weeks ago. An air-pipe is being laid. Water is receding.

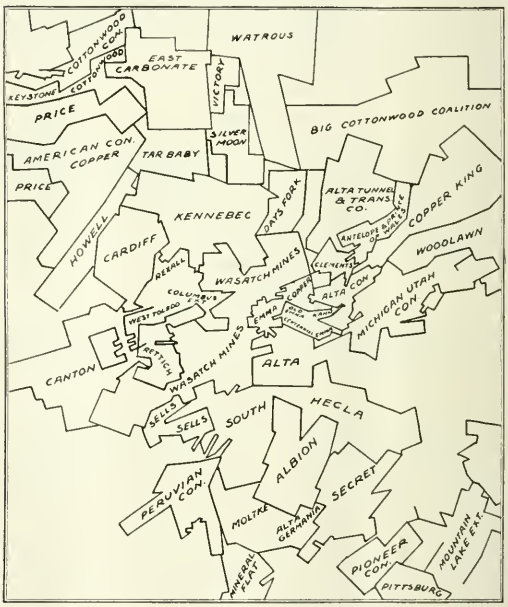
The South Hecla mine is yielding 80 tons of ore per day worth from $12 to $30 per ton.

At 600 ft. depth in the Alta Tiger 18 in. of high-grade silver-lead-copper ore was cut last week.

At the top of No. 1 raise in the Sells mine there is three feet of ore, while other parts of the property are developing satisfactorily.

The Alta Consolidated company is preparing to ship ore.

The Alta Cottonwood Railway Co. has been organized with a capital of $100,000 to construct a line into the Little Cottonwood district from the Salt Lake & Alta railroad. The new line will work on the cog system, will have snow-sheds, will



THE COTTONWOOD DISTRICT, UTAH.

charge $1 per ton for freight, and will be equipped for 1000 tons per day.

The Koehring cyanide process has been tried at the Wasatch-Utah Mining Co.'s mill near the mouth of Little Cottonwood canyon.

The Bingham-New Haven company is suing the Utah Metal & Tunnel Co. alleging that the latter has extracted ore worth $100,000 from the Levant lode, the apex of which is claimed by the complainant.

WASHINGTON

King County

The mineral deposits of the Skykomish basin are described in the Columbia University *School of Mines Quarterly* by Warren S. Smith. It is part of a report prepared for the Washington State Geological Survey, but not heretofore published. Work in the Berlin district dates back to 1892. The Apex and Cleopatra were about the first claims located in that year, the former sending out $80,000 of ore on horseback before the wagon-road was made in 1901. Early shipments from the Cleopatra yielded $132 per ton. A number of properties on Money creek reached the height of their activities between 1900 and 1905. A great deal of work, mostly as adits, was done at great expence with little result, the exploration not being judiciously planned. At the present time little is under way, although some optimism prevails. The ore minerals are

chiefly original sulphides, such as arseno-pyrite, pyrite, sphalerite, chalcopyrite, and galena. Treatment is difficult, smelting being the only successful method. Free-milling ore does not exist. The sulphides are very fine, and ordinary water concentration does not give good results.

KITTITAS COUNTY

(Special Correspondence.)—Considerable excitement exists here owing to a recent discovery on the Silvanite quartz claim, which is situated north of here on Iron creek. The vein, which is from 8 to 20 ft. wide, yielded assays from $7 to $160 gold per ton. The owners are Brooks, Heidluff, and Maxfield of Seattle. It has been known for some years that several large lodes existed up on the Swauk, prospecting and development was done at different times, and assays have given 80c. to $80 per ton. The owners have had a mill test and analysis made of their ore, and find that it contains sylvanite, a telluride of gold. The company will employ about 18 men. It is erecting a bunkhouse, etc. A shaft and cross-cut adit has been started. This is very important to the Swauk district, as the main interest has been centred in placer mining. There are many large low-grade lodes and dikes that will probably be investigated.

The Home Rule placer shipped 26 oz. of gold dust to the U. S. Assay Office at Seattle this week. H. D. Harkness is the owner of this property.——H. M. Mumford has taken a lease on the Vendetta placer claims on Lions gulch, owned by Powers & Sugars.

Liberty, September 11.

CANADA

BRITISH COLUMBIA

The Rambler-Cariboo Mining Co. will pay 1c. per share, equal to $17,500, on October 15. This is the first dividend for some time. Another similar sum will be paid in December. The mine is at Three Forks, and produces lead-silver and zinc ores.

ONTARIO

The output of metalliferous mines and works of Ontario for the six months ended June 30, as reported to the Ontario Bureau of Mines, is shown by the following table, which also gives the production for the corresponding period of last year:

	First half of 1915.	First half of 1914.
Gold	$3,570,072	$2,011,069
Silver	5,188,763	7,053,418
Copper	1,229,894	1,197,059
Nickel	3,393,528	2,872,843
Iron ore	288,296	118,119
Pig-iron	2,856,040	4,429,664
Cobalt	34,443	22,581
Cobalt oxide (including nickel oxide)	56,812	379,152

Porcupine produced $3,267,620 of the gold yield, and at the same rate the year will show an increase of 50% over that of 1914. Developments in all the gold areas are good. Part of the lessened output of silver is due to the low price of the metal. A feature of recent operations at Cobalt is the development of a series of rich veins by the Mining Corporation of Canada under the town. The output of nickel has never been so great as it is at the present time. Demand is insistent, and the producing companies are working their mines and smelters at full capacity. Compared with the corresponding period of 1914, the value of the copper output increased by over 2% and nickel over 18%. The quantity of ore raised was 548,579 tons, and of ore smelted 550,870 tons. The Canadian Copper Co. and the Mond Nickel Co. are the producing concerns. On account of the War the market for cobalt oxide, Europe, is closed, and the output decreased considerably.

An illustrated description of the new Kowkash goldfield is published in the *Canadian Mining Journal* of September 15. A geological reconnaissance was made for the Canadian survey in 1903-'04 by W. J. Wilson. Cobalt men left last week for the region, some with enough supplies to last through the winter.

PERSONAL

F. H. Sistermans has gone to Los Angeles.

LEON J. PEPPERBERG has returned from Texas.

D. C. BARD, of Butte, has been in British Columbia.

H. E. WEST has returned to his home at Santa Barbara.

H. H. WEBB has quite recovered from his recent accident.

BEN. S. REVETT has returned from Colorado to San Francisco.

HENRY KRUMB and F. S. SCHMIDT of Salt Lake City are in Alaska.

BEN. B. LAWRENCE is expected here from New York, by way of Spokane.

J. DAWSON HAWKINS, who has been on a holiday to Tahiti, has returned to Denver.

L. D. RICKETTS was called to Cananea by the latest development of Mexican misrule.

E. L. GRUVER passed through San Francisco on his return from Dawson to New York.

J. M. TURNBULL has been appointed Professor of Mining in the University of British Columbia.

PERCY HOPKINS, of the Ontario Bureau of Mines, has examined the gold discovery at Kowkash.

STANLY A. EASTON, manager of the Bunker Hill & Sullivan mine, has been in San Francisco this week.

R. B. LAMB has moved temporarily from Toronto to New York, where his office is at 15 Cedar street.

W. H. SHOCKLEY has been assisting the Editor of the MINING AND SCIENTIFIC PRESS during the past two months.

NICHOLAS S. PENN, of the Imperial Institute of Technology, at Tomsk, Siberia, is visiting Grass Valley, on his way back to Russia.

J. D. CONNOR, metallurgist for the Government of South Australia, is here and will investigate the leaching of copper ores in the United States.

JOHN M. BOUTWELL has finished his detailed report on the Old Dominion mine at Globe, Arizona, and passed through San Francisco on his way to Salt Lake City.

HENRY M. RIVES has resigned the secretaryship of the Nevada Industrial Insurance Commission to accept a similar position with the Nevada Mine Owners' Association. Mr. Rives was formerly with the Pittsburg Silver Peak Gold Mining Co., and a member of the Assembly from Esmeralda county at the last session of the Legislature.

Schools and Societies

The Montana section of the A. I. M. E. will meet at Butte on October 8. After the dinner the paper of J. A. Grimes and Paul Billingsley 'Preliminary Outline of Paper on Mines in the Boulder Batholith' will be read and discussed.

The August Bulletin of the School of Mines and Metallurgy of the UNIVERSITY OF MISSOURI, at Rolla, contains a paper entitled 'Comparative Tests of Piston-Drill Bits' by Professors C. R. Forks and L. M. Cummings, which is worth securing.

Dr. James Douglas, of New York, has offered $150,000 to the McGILL UNIVERSITY, Montreal, toward the cost of erecting a students' residence, and the board of governors has accepted the donation. Dr. Dougles has been tendered the honorary position of Chancellor of Queens University, Kingston, and it is understood that he will accept it.

The College of Engineering, UNIVERSITY OF ILLINOIS, at Urbana, reports the following new appointments to its staff, effective September 1: A. U. Bleininger, W. M. Hekking, C. V. Burger, L. C. Dillenback, C. S. Sale, C. S. Fazel, H. R. Fritz, F. A. Kirkpatrick, L. Y. Larson, W. A. Manuel, L. A. Mylius, B. R. Ordonez, S. F. Tenabe, R. L. Templin, and C. Weiss.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, September 30.

Antimony	35 —35¾
Electrolytic copper	18¾—19
Pig lead	4.75—5.70
Quicksilver (per flask)	$90
Spelter	17 —17¼
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	29

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, September 30.—Copper is firm owing to good exports and sales; lead is strong, prices unchanged, but an advance expected; zinc had a slight downward move.

COPPER

Prices of electrolytic in New York, in cents per pound.

The silver market is firm. In London, according to Pixley & Abell, continued steadiness is expected, provided China does not attempt heavy sales. Exports of metal from London to India and China to September 8 were £3,348,250, against £4,508,000 in that period of 1914. Buying orders from India and the Continent have given a stronger undertone to the market.

On October 20 the Nipissing company pays 5%, making 20% for the year, equal to $1,200,000, and $13,440,000 to date. On the following day the Tonopah Mining Co. distributes 15%, or $150,000, making $13,000,000 to date.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

The average basis price for zinc concentrate in the Missouri-Kansas-Oklahoma region to September 25 was $76.37 per ton. Last week there were few changes. The output was as follows: 6428 tons blende, 290 tons calamine, and 1022 tons lead, averaging $71.02, $50.44, and $50.22 per ton respectively. The total value was $525,474, and $17,216,239 for 39 weeks.

The Edgar Zinc Co. has opened an office at Salt Lake City, and will buy Utah zinc ores.

Commercial spelter is divided into four grades, which have been defined by the American Society for Testing Materials as follows: (a) high-grade, not to contain over 0.07% lead, 0.03% iron, 0.05% cadmium, and be free from aluminum, the sum of lead, iron, and cadmium not to exceed 0.10%; (b) intermediate, not to contain over 0.20% lead, 0.03% iron, 0.50% cadmium, and be free from aluminum, the sum of the lead, iron, and cadmium not to exceed 0.50%; (c) brass special, not to contain over 0.75% lead, 0.04% iron, 0.75% cadmium, and be free from aluminum, the sum of the lead, iron, and cadmium not to exceed 1.2%, and (d) prime western, not to exceed 1.5% lead and 0.08% iron.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

One of the most interesting features of the lead industry is the smelter to be erected by the Bunker Hill & Sullivan company of Idaho.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	37.85	34.40	July	31.60	37.38
Feb.	39.76	37.23	Aug.	50.20	34.37
Mch.	38.10	48.76	Sept.	33.10	....
Apr.	36.10	48.25	Oct.	30.40	....
May	33.29	39.28	Nov.	33.51	....
June	30.72	40.26	Dec.	33.60	....

Tin is steady at 33 to 33.50c. per pound.

ANTIMONY

Demand has continued dormant and while the quotation for metal in bond continues at 26c., this figure might be shaded. Antimony out of stock can be had easily at 28.25c., the available grades, of course, being Chinese and Japanese.

ALUMINUM

Prompt metal has been quoted at 48.50c., but can be had at 46.50 to 47.50c. It is exceedingly scarce, and scrap is eagerly sought for at prices higher than those of new metal a few months ago.

Eastern Metal Market

New York, September 24.

The uncertainties of these war times continue to be exemplified by the metal market. Copper has been exceedingly dull, with electrolytic stronger than Lake. Exports are light. After a series of reductions, zinc took a turn upward on September 22, and again there are allegations of manipulation, but it is certain that spot and prompt spelter are not easy to obtain. Lead has been steady at the quotation of the leading interest, to which strength has been imparted by a strong tone at London. Tin dropped to 32.25c. in a stagnant market. The market is over-supplied with unsold metal, and all the indications are for a substantial increase in surplus stocks at the end of the month. Antimony has been dull, weak, and uninteresting. The scarcity of aluminum has caused the quotation for spot metal to advance to about 48c. The entire market depends considerably on the successful negotiation of the foreign loan negotiations, now near at hand, [arranged on September 28.—EDITOR], one effect of which is expected to be the restoration of foreign exchange to somewhere near its normal level. The English pound sterling was quoted yesterday at $4.71.

In iron and steel the general tendency to advance continues. Wire products are $2 per ton higher, principally because of export demand. It is expected that plates, shapes, and bars will go to 1.40c. base, Pittsburg. Several products, other than wire, are higher. The demand for steel for large sizes of explosive shells is exceedingly heavy, and calculated to make serious inroads on the supply. Foundry iron is quiet, and has not the prospect of heavy demand that faces steel-making iron. Steel is not easy to secure to-day in any form. Exports of iron and steel in July totaled 368,893 tons, against 355,829 tons in June, 114,790 tons in July, 1914; 237,159 tons in July, 1913, and 272,778 tons in July 1912.

COPPER

An interesting feature of the copper market is the unusual relation existing between Lake and electrolytic quotations. The asked-price of electrolytic is considerably firmer than that of Lake; also higher if all grades of Lake are taken into account. Despite the fact that business has been very quiet, the electrolytic quotation has continued firm at 17.75c. cash, New York, whereas Lake has been soft, and offerings of low-grade metal have been made down to 17c. cash, New York. Important producers seem to have a great deal of faith in the future, inasmuch as they continue to quote electrolytic at 18c., 30 days, delivered; but it is pointed out that with no interest shown by consumers they might as well quote 18c., as any price. Prime Lake has been sold in the past few days at 18c., but not in large quantities. The exports make a poor showing, amounting to 8823 tons up to September 24. Much speculation is rife as to the causes of the present stagnation. By some it is pointed out that pending the settlement of the foreign loan nothing but quiet can be expected; also, the rate of foreign exchange is considered. Another explanation is that the manufacture of ammunition has been slow in getting under way, and that the makers have not yet consumed the metal they bought when they booked the contracts, and still again, the incessant strikes are held accountable to some degree for the situation, inasmuch as they have at least made war contractors more or less timid. Arsenical brands of Lake are in very light demand. The optimistic side of the market is that every prolonged period of inactivity is the forerunner of a good movement when consumers do bestir themselves. The European visible supplies on August 31 amounted to 39,237 tons, against 41,716 tons on the 14th, a decrease of 2479 tons. The general opinion is that production is running ahead of deliveries, but how much is merely a matter of opinion.

ZINC

Allegations are heard again of efforts to manipulate the market; first to depress prices, then to advance them. However that may be, it is certain that the quotations for prompt metal declined until September 22, when there was a sudden and decided turn upward, the price going from 13.25 New York, to 13.75c., while on the 23rd, 13.87½ to 14c. was quoted for prime Western. On the 24th it advanced to 14.25c., New York. What activity there has been has been almost entirely confined to prompt metal and deliveries to the middle of October all of which are scarce. Consumers evidently have no incentive to make contracts. Brass-mill special was quoted this week at 16c., and high-class grades (though not the very choicest) have been quoted at 27c. The London market has been weak. The market for galvanized sheets is easier and prices somewhat irregular. No. 28-gauge are quoted at 3.45c., but some of the heavier gauges are relatively cheaper. The demand is exceeded by that for black and blue annealed sheets, which, contrary to galvanized, are strong.

Sheet zinc is quoted at 16c., f.o.b. smelter, subject to the following discounts:

	Cash with order	Quantity	Total
	%	%	%
Carloads	3	5	8
9000-pound lots	3	3	6
6000-pound lots	3	2	5
3000-pound lots	3	1	4
Less than 3000 pounds	3	.	3

Exports of spelter from September 1 to 24 amounted to 2635 tons.

LEAD

There is little to say about this metal except that while the market has been uninterruptedly dull, quotations have not been impaired appreciably. On one or two days there was a little disposition shown by second-hands to sell at slightly under 4.50c. New York, the quotation of the A. S. & R. Co. Late this week all concessions disappeared, and the market took on a firm tone, so much so that sellers were not eager to sell, and it is thought that quotations will advance. The London market has been strong, and has gained steadily. Export inquiry has shown a decided betterment, a part of it coming from Japan. The exports of the month, up to the 24th totaled 1730 tons.

TIN

Suffering from an over-supply, the tin market has declined heavily. The quotation on September 23 was 32.25c., and on the next day, 32.50c. with practically no demand, in fact, the market has been at a standstill for days. Up to the 24th the arrivals totaled 4693 tons, and there was afloat on that day 2810 tons, all of which indicates a large increase in stocks at the end of this month. On the 21st the quotation was 33c., and at that time sellers considered that business would start at 32.50c., but they feared a decline, inasmuch as it might not stop at this price, and that is just what happened. Aside from the over-supply, the foreign exchange situation is having an adverse affect on the market. In reflection of the weak condition here, spot tin in London declined £2 on September 23. Meanwhile the demand for tin-plates is slowing up. The imports of tin at Pacific ports in July aggregated 1,162,025 lb. (value $405,242) at San Francisco, and 963,789 lb. (value $335,602) at Washington.

On September 3, Henry R. Merton & Co., of London, stated that the margin between standard copper and electrolytic brands was £16 per ton, far greater than for many years. Lack of speculation and high prices of American copper are responsible.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.
6s-12 oz.-40s	8¾	6s-14 oz.-40s	9¼

ALUMINUM

The production of bauxite in the United States during 1914 was 219,318 tons, valued at $1,069,194, or $4.87 per ton. Alabama, Arkansas, Georgia, and Tennessee were the principal producing states. Imports amounted to 24,844 tons worth under $1 per ton. The world's output is nearly 500,000 tons per year, France leading. From this mineral the metal aluminum is reduced, at Niagara Falls, by electricity. The yield of the United States in 1914 was 79,129,000 lb., and of the world in 1913, 45,700 metric tons. Of this France produced 18,000; Austria, 12,000; England, 7500; and Canada, 5900 tons.

EDITORIAL

T. A. RICKARD - Editor

SHEET-ZINC is now quoted on our metal page. The quotation will interest those using this form of spelter in cyanide plants.

GOLD inflation and fabulous earnings by munition manufacturers suffice to explain the hysteries of Wall Street, but the danger of the gambling in war stocks is thoroughly understood and well discounted.

JOHN D. ROCKEFELLER, JR., has made himself almost popular by his informal visit to the coal mines in Colorado. Such attempts to become reasonably well informed concerning their employees should be made so frequently by the beneficiaries of big industries as to be considered normal, not eccentric.

BETHLEHEM STEEL is the product of Charles M. Schwab's organizing ability, and it is an illustration of the loyal co-operation of a small group of hard-workers. Without big salaries, but by premiums on production and on economic management, several of Mr. Schwab's junior associates have made large fortunes, to which they are fully entitled under the conditions of an industrial civilization.

OATMAN is a promising gold-mining district, as was shown in the article by Mr. Howard D. Smith published by us on July 31, but the reputation of the district will only suffer from some of the ill-considered efforts now being made to boom it. In one of our local organs of misinformation we read that Oatman "will develop a gold output of extent and value comparable with the great Rand gold belt of South Africa." The Rand produces $180,000,000 per annum. Such comparisons only render Oatman ridiculous.

ELM ORLU is the name of the mine now in litigation with the Butte & Superior. It is a corruption of ormolu, a gold-colored alloy. We understand that Mr. W. A. Clark is a large holder in both mines, but we do not presume that he is acquiescing in the expense of litigation in order to clarify the legal record. If Mr. D. C. Jackling held a large block of shares in the Elm Orlu, as well as in the Black Rock, the coincidence might suggest a friendly collusion to aid the experts, legal and geological, to whom the case will be a source of intellectual exercise and, possibly, of revenue.

A VISITOR from Oatman, Arizona, tells us the stopping of the sale of liquor has helped mining, for a number of the miners who formerly spent their money on drink have formed development companies and are sinking shafts through the rhyolite cap in search for ore. Geologically, conditions in the Oatman district are similar to those in that part of Tonopah where the veins are covered by a flow of eruptive rock. At Oatman the caprock is a rhyolite that is later than the vein-formation. The ancient surface, existing at the time of this rhyolite flow, can be traced by following the line where the rhyolite has softened the rock below it.

COPPER production is suffering to the extent of 6,000,000 pounds per month from the strike in the Clifton, Morenci, and Metcalf districts. The managers of the Arizona, Detroit, and Shannon companies have left the mines, after having refused to meet the labor leaders in conference, for the reason that the Western Federation is at the back of the trouble. Strikes, started by the same agency, failed at Miami in February and at Ray in July. The question of wages is subordinate to the attempt of a lawless coterie to dominate labor in this part of Arizona. Similar attempts in Utah, Michigan, and Montana have been made during the last two years, but they were unsuccessful.

ACCORDING to recent advices the Russian government has sanctioned the building of a railway to connect the Bodaibo goldfield with the Trans-Siberian main line. This branch will run from Tataurovaya through Barguzin and prove of great benefit to several companies, notably the Lena Goldfields. We note also that the distribution of several hundred thousands of German and Austrian prisoners of war in the interior of Siberia is going to have a great effect on the future development of the country, for many of these involuntary immigrants will never go back, having found opportunities to suit them. Thus the War may accelerate the industrial advancement of an important mineral region.

IN the *Mining Magazine* we find a reference to the interesting fact that the shareholders of the Talisman Consolidated, operating a mine in New Zealand, are proposing to remove the office and administration of the company to New Zealand, where also the control of the stock is held. This is to be done in order to avoid the high income-tax now payable in England. We happen to know that this payment of war-taxation is a little annoying, for example, to some of the California shareholders in the Plymouth Consolidated. As a matter of fact the payment of income-tax on the dividends from a mine is a glaring fiscal fallacy, because such a dividend is not income until the capital has been redeemed, and

that does not often happen when, as is usually the case, the mine is over-capitalized. But the promoters of mines, in London and elsewhere, are to blame if the tax-collector treats dividends as income, the misunderstanding having arisen from the effort to exaggerate the value of mines by labelling the profit from a wasting asset as a return on capital. Nevertheless, it is an injustice to the public, and to the industry, in so far as it mulcts the shareholders of a part of their legitimate winnings. With an income-tax at about 17%, this becomes a serious matter to shareholders, whether British or American, although the former at least will be ready to recognize the fact that mining in its world-wide aspect would be utterly paralyzed today had not the British navy kept the trade-routes open for the large majority of those engaged in overseas mining.

EARLY in September three incendiary bombs were dropped upon Salisbury House, where *The Mining Magazine* is domiciled. No serious damage was done. Another bomb fell through London Wall Buildings and several on Moorgate Street. This, the only Zeppelin raid that did any harm to London, occurred at night on September 8. The result was to kill a few inoffensive persons and to start some minor fires, besides affording plenty of work for the glaziers. The September issue of the *Magazine* shows no signs of disquiet. As many of our readers are aware, the copies of the August issue consigned for this side went down on the *Arabic*. We trust that this may prove the worst bit of ill luck to befall our London contemporary.

STATISTICS of foreign commerce reflect the remarkable developments of the past fiscal year, to the end of June, but they are not truly indicative of the big changes in progress because the depression during the early part of the fiscal period tends to obscure the growth of trade during the second half of the year. We give some of the metal statistics herewith:

		1915.	1914.
	IMPORTS		
Copper,	unmanufactured	23,208,960	19,456,588
	Manufactures	46,205,123	70,704,828
Tin	"	30,777,617	39,422,479
	EXPORTS		
Brass	"	20,544,549	7,472,476
Copper	"	99,778,177	149,479,645
Lead	"	9,044,479	2,610,207
Zinc	"	21,939,253	995,077

These show how the export of copper to Europe in preparation for the War was bigger than any trade movement since then, but the exports of brass, lead, and zinc, especially the last, have increased enormously. Of course, the brass includes a large proportion of copper.

MEXICAN AFFAIRS are simmering quietly, in expectation of the lid being raised again shortly by the Pan-American conference. The scare in the North has abated; uneasy quiet reigns through Chihuahua. Villa has damaged the railway so that Carranza cannot advance in a hurry. The American and British consuls are remaining, together with a considerable number of their respective nationals. A few mines scattered over the country are doing a little development work for the better protection of property and to keep their men from starvation. The Alvarado mine at Parral is producing enough ore to keep the mill going. The eastern side of the north country, through Monterrey and Saltillo, is now less disturbed, having passed under the control of Carranza's troops. Trains are being run with some attempt at regularity between Laredo and Saltillo, and occasionally down to San Luis Potosi and even to Aguascalientes. No attempt is being made, however, to transact business. The lack of food has been pitiful, even corn not being available. Carranza, of course, says the Red Cross need not send supplies, but gaunt famine stalks across the devastated land. The general impression at El Paso is that the present enforced idleness of the mines and smelters will last until the end of the year, at least. For the rest, the hope of restoring order out of chaos rests in the hands of the Administration at Washington and of their Pan-American coadjutators, all of whom have as yet done nothing beyond the publication of pronunciamentos, which are regarded as 'scraps of paper' by the leaders of faction in Mexico.

ACCIDENTS in mines and their causes was the subject of an acrimonious discussion at the meeting of the American Mining Congress at the session of September 22. Mr. Harry L. Day, of Wallace, Idaho, contended that two-thirds of the mine accidents were caused by the carelessness of the miners. His statements were vigorously combatted by Mr. Frederick L. Hoffman, statistician of the Prudential Insurance Company, and by Mr. Herbert M. Wilson, director of safety for the Associated Mining Companies. It is quite possible that Messrs. Hoffman and Wilson have access to statistics of which we are ignorant, but as far as our information goes it supports Mr. Day's contention. Our own personal experience is that most of the accidents in the mines we have managed have been due to the recklessness of the miner, and to his direct disobedience of rules. Tell a miner as often as you will that he should not keep fulminating caps and dynamite in the same place, and explain to him the danger of carrying dynamite and capped fuse in the same pocket with the caps perilously near his lighted candle, and yet the next time you go through the mine you will find the box of caps quietly reposing on the box of dynamite, or the miner climbing down a ladder with his waving candle within a few inches of the dangerous caps. Glancing at the summary of causes of accidents that is contained in a recent paper by Mr. W. H. Shockley, we find that the report of the Pennsylvania Department of Mines for 1913 gives the carelessness of the deceased as the cause of 61.6% of the deaths for that year. Mr. Charles W. Goodale states that 85% of the accidents at Great Falls, Montana, are due to carelessness. The Inspector of Mines for Montana also finds that "the great danger lies in the acts of ignorant and irresponsible laborers and miners who take unnecessary risks in defiance of law and common sense." We invite discussion on this important question.

Valuation of Mines

At the recent Engineering Congress the subject of valuation as applied to oil, coal, and metal mines was discussed in various papers. Of the three divisions of the subject, that relating to the precious metals and to the chief base metals, omitting iron, is the most important to our readers. It might be well to distinguish between mines of gold or silver ore, on the one hand, and mines of copper, lead, or zinc on the other, for the deposits of the precious metals have characteristics different from those of the base metals, but for the purpose of a general discussion this is not necessary, although we may agree that the distribution of gold and silver in nature in concentrations of mineral is more erratic and therefore more hazardous, from the miner's standpoint, than that of the commoner metals. Yet we must add that the increased hazard is compensated by the greater possible gain. Here we strike the key to a discussion of the subject from the business side: the recognition that in any enterprise we must take pains to ascertain whether the gain is proportioned to the risk. To make an even bet on a particular horse out of a field of a dozen horses is, if this be done systematically and often, a sure way to pauperism. To buy railroad shares on a 3% basis, when Government bonds yielding the same returns are available at the same price, is not sagacious. To appraise the common shares of the U. S. Steel Corporation on the same basis as the bonds of that corporation is manifestly foolish. Speculation in the common stock has possibilities, both up and down, of winning and losing, that are eliminated from the investing of money in the bonds. In one case it is the possible enhancement of the principal, in the other the assured dividend, that is likely to prompt a purchase.

Mining has suffered from the unwise, because untrue, idea that it affords opportunities for investment. That may be true, or not, of iron mines and coal lands; we are referring now to what are called precious-metal and base-metal mines. In consequence of the investment idea, the element of risk has been minimized so that the return expected from the use of money in mining has been put too low to be profitable in the long run. To buy Rand gold-mining shares on a 5% basis is stupid, because it ignores the dangers inseparable from the vicissitudes of that particular industry; to purchase Alaskan gold shares for a 7% return is to disregard the risk inherent in a business in which so many of the factors are both variable and uncertain; yet these are supposed to be among the least risky of mining ventures. To talk of a productive low-grade copper mine as "a manufacturing proposition" or a successful silver-lead mine as "a gilt-edged investment" is to flout all the experience of the years. Such enterprises indeed may prove to be gloriously profitable ventures and magnificently remunerative speculations, but the element of safety is absent from any business that exposes a man's money to the ineradicable hazard of adventure. The result of this mirage of unhealthy optimism, whereby the promoter sells to the public a watered stock as if it were a bond, is to hurt mining deeply. In short, we believe that by this confusion of ideas between investment and speculation, the whole finance of mining has been pitched too high; to use a musician's phrase, it has been pitched a third too high. That does not mean 33⅓%. It means that the tone of discussion, more particularly of the practical discussion that ends in appraisal, has been conducted in the wrong key, causing a falsetto that has spoiled the harmonious progress of a world-wide industry. If the risk, and the corresponding gain, of course, in mining were properly recognized, and the use of money for the purpose were adequately remunerative, not only to the few who get in on the ground-floor but to the many that take the elevator of a boom, we should see more general participation by the public and more liberal support by the community at large.

In the article on another page it is shown, we believe, that most of the published methods of appraisal are fundamentally wrong because they proceed to treat a mining venture as an investment. At the end of the measuring and sampling, of the estimating of yield and cost, of the allowances for depreciation and deductions for amortization—when the whole of this deeply serious performance is ended—the engineer has to face the question as to what percentage of profit is required to make the venture a sound business. He must consider the risk involved in the search for ore in a particular district and the hazard inherent to the winning of a metal of changing market-value. And then he must estimate the risk involved in the particular mine and its management. Just as the same engineer, if he were to become the agent of an insurance company, would have to consider the average longevity of man, the average longevity of persons residing in a particular country or pursuing a particular vocation, and in the end he would have to estimate the risk involved in the insuring of the man before him. Of course, he would have all history to guide him, he would have actuarial records to help him, he would have the facts concerning the family, more particularly the parents, of the subject of his investigation; he would have a vast array of systematized knowledge at his service. What has the engineer? The cumulative knowledge on the duration of mines is not 50 years old; in some kinds of mining it does not cover 25 years. The stories of only a few mines have been placed on record, and those relate to the exceptionally profitable and persistent. Such knowledge as lies scattered in the minds of experienced men is not available for general use; all that we get are scraps of information. The bulk of the valuable experience dies with the individual, because it is of the kind that the exigencies of a professional career render unsuitable or undesirable for publication. To change the analogy: the engineer is like a physician who has seen only a few post-mortems, and for that reason is an unsafe diagnostician. What is needed, in order to lessen the insecurity of mining as a business, is last year's almanac, in adequate detail: a record of the estimates made on mines and a statement showing how those estimates stood the test of subsequent events. We need a collection of reports by the best hundred engineers in

the profession during the last 50 years, together with the history of the mines during the five or ten years after the dates of the respective reports. In this way we would get the data by which to determine the risk involved in the use of money for mining, and thus we should arrive intelligently at the percentage of profit required to justify the employment of capital in such operations. That would be a scientific approach to the solution of a great problem. When we had done it, we could not fail to be impressed by the folly of appraising mines on an investment basis; we would learn that mining is essentially speculative; we would conclude confidently that when pursued sanely, the gain more than compensates for the risk, so that in the end the sagacious speculation may be more profitable than the timid investment.

The Teaching of Mining

On another page we publish an article on 'What Constitutes a Mining College.' It is written by an engineer so lately graduated as to be in touch with the present methods of teaching and yet sufficiently long in the arena of life to be able to appraise the effectiveness of that teaching. We get the views of professors on this subject often enough; it is well to hear from their victims or beneficiaries. Undoubtedly the number of institutions organized to teach mining is excessive; every little provincial university nowadays seems to think it proper to include a course in mining in its heterogeneous curriculum. Even in States where the average citizen can hardly distinguish a mine from a submarine, the attempt is made to teach the youthful farmer how to dig holes beyond his depth. In other localities, within sight of a head-frame and within hearing of the cheerful whistle that marks the arrival and departure of those that go down in skips, it does seem unwise to try to teach a most difficult subject unless it can be done with some approach to thoroughness. At the present time, we know that several mining schools are languishing both for lack of capable teachers and of the financial support that not unnaturally is proportioned to the number of students, as indicating the apparent demand for a special course of instruction. On the whole, we think it is easier to find the students than the teacher, and for that reason, among others, we deem it a pity to see so many half-baked efforts at the maintenance of a school of mining. Indeed, the lack of good teachers of a subject so difficult to teach—because it is essentially practical and empirical—is the main objection to the multiplicity of courses in mining. In some institutions of academic distinction it appears to have been assumed that the erection of a marble mausoleum to the memory of a deceased plutocrat or the construction of a granite museum to the honor of a late philanthropist suffices to make a school of mines. On the whole, we think that in a country so rich and generous as the United States it is easier to get the money for resplendent buildings than to find the men to convert those buildings into something more than mere sarcophagi of knowledge. Out of the many men made depressingly rich by the boom in war-stocks there ought to be one willing to endow a department of mining generously on condition that an amount no larger than the annual salary of the professoriate be spent on the building and its adjuncts; in short, we would like to see a department of mining endowed so that the professor could have ample opportunity to travel and gather information, and be released, in his turn, for at least three months every year, from any contact with the students: in other words, provided with the chance to absorb new impressions and fresh facts, as against the nine months when the professors are giving out freely from their store of knowledge and experience.

In the article by Mr. McDonald it is said that the essentials of the real mining college are two, the first of which is "location and equipment." Certainly, a school of mining should be either where there is population or where there is mining, as a smelter is established either where ore is plentiful or where fuel is cheap. For a purely mining school the neighborhood of a mining district is preferable; for a university in which mining is only a department, a centre of population is desirable. We do not consider the vicinity of mines essential, if the students use their long vacation to see something of the realities of the work for which they are preparing. To understand mining a man must first understand many other things, he must have a foundation of scientific principles, which are taught best in a university or a technical college, such as rarely exists near the mines themselves. But this is a minor point, it is the second that is all-important, namely, the personnel of the professors and instructors, the tone of the school as given by its president and faculty, the spirit animating the student-body. To learn anything, even Greek or biology, thoroughly from a great teacher is more educative to an earnest student than to listen to the daily maunderings of a small mind; to come under the influence of a character-making man like Huxley, Le Conte, or Shaler is more to a young man than all the lectures of a petty personality. As Shalers and Le Contes are rare, it behooves us not to over-work them with departmental and routine duties when they are available for the greater work in hand. In these days, the teacher in a big school of mines is burdened with a lot of trivial tasks that undermine his physical strength to an extent not appreciated until it is too late. We have in mind one teacher, beloved of his students, who has given to red tape what was meant for mankind; until the high sense of duty has resulted in a mental fatigue from which recovery is not easy. Such a teacher is worth more than a marble hall, and impresses a generation of young men more than all the apparatus that was ever furnished to a mining school. Have we digressed from our subject? No. The teaching of mining, with which we associate metallurgy and geology, is a matter of character and personality more than multiplicity of schools or magnitude of college buildings. An institution is the lengthened shadow of a man.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Surface Tension

The Editor:

Sir—In your editorial on 'Flotation at Broken Hill' in your issue of September 4, 1915, page 343, you made a statement regarding surface tension that is rather befogging to a student of flotation. It is as follows: "Mr. Hebbard says that the surface tension was increased by the salts introduced, but, we venture to suggest that the opposite was the fact."

Surface tension has been threshed out pretty thoroughly by articles appearing in the Journals of the Ameriean Chemical Society, beginning in 1908.

Jour.	Am.	Chem.	Soc.,	Vol.	XXX,	No.	3,	March	1908
"	"	"	"	"	"	"	7,	July	1908
"	"	"	"	"	XXXIII,	"	3,	March	1911
"	"	"	"	"	"	"	5,	May	1911
"	"	"	"	"	"	"	7,	July	1911
"	"	"	"	"	XXXV,	"	10,	October	1913
"	"	"	"	"	"	"	11,	November	1913
"	"	"	"	"	"	"	12,	December	1913

These articles deal with the drop-weight method (weight of a falling drop) for the determination of molecular weight, critical temperature, and surface tension, and they describe the apparatus used. The work was started by Morgan and Stevens, who wished to investigate what had become known as the law of Tate.

Tate, in 1864, had made a generalized statement about the relation of weight of drop to diameter of tube, the weight that could be raised by capillary action, and the temperature of the drop. Some of their conclusions are that:

(*a*) The drop-weight of any liquid is proportional to the diameter of the dropping-tube (these tubes are uniform in diameter, thus differing from the ordinary burettes).

(*b*) The weight of a drop, other things being the same, is proportional to the surface tension of the liquid.

(*c*) That it is possible to calculate the temperature at which the drop-weight would become zero, namely, the critical temperature of the liquid, for at that point the drop would disappear, there being no distinction between the gas and the liquid.

In the course of these experiments the surface tension of a number of organic liquids in aqueous solution was determined by drop-weight and found to range from 21 up to that of water. The tabulated results cover several pages in the *Journal*; I have copied a part and condensed into one table, which is given below.

It is to be noted that in all cases the very first addition causes a very considerable lowering of surface tension. The deerease in the surface tension of water caused by the addition of a very small amount of amyl alcohol is especially striking. Thus the presence in solution of even so small an amount as 0.25% changes the surface tension of water from 71.03 to 53.7, or nearly 25% at 30° C.

Morgan and Schramm studied many concentrations of a few salts. They seleeted the molten hydrated salts for this purpose; those salts which melt below 50° in their own water of crystallization being especially satisfactory for this purpose, for the reason that concentration in some of these cases could even be carried to super-saturation.

In the case of the salts which they studied it is plain that surface tension is increased by the salts introduced. Where calcium chloride was used, the surface tension was increased from 71.03 to 102.57, approximately 50%. Taking a few specific cases it is noted that to increase the surface tension 10% it would take

20% $CaCl_2$ at 30°
43% $Zn(NO_3)$ at 45°
29% Na_2CrO_4 at 30°
34% $Na_2S_2O_3$ at 40°

The diagram is appended. See Fig. 1.

tion that equivalent salt solutions exhibit identical values of surface tension is shown by plotting the same results reduced to molecules of water to molecules of salt. But one must be careful not to carry generalizations too far because this does not hold with some salts. The diagram is appended. See Fig. 2.

The fact is that some salts elevate while others depress surface tension, but the former predominate. In addition to the salts just mentioned, the tartrates, carbonates, oxalates, citrates, lactates, and a part of the acetates raise surface tension; while the salicilates, the butyrates, part of the acetates, and all the acids lower surface tension. It is suggested that the liberation of free acid by hydrolysis in the case of salts of weak acids may cause their negative effect on water.

All acids lower surface tension, and in the case of the fatty acids experiments have shown that the lowering is proportional to the carbon content of the acid.

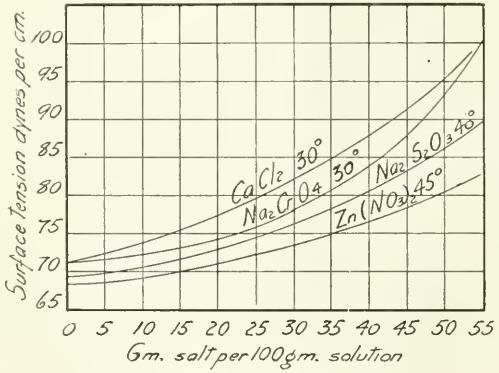

Fig. 1.

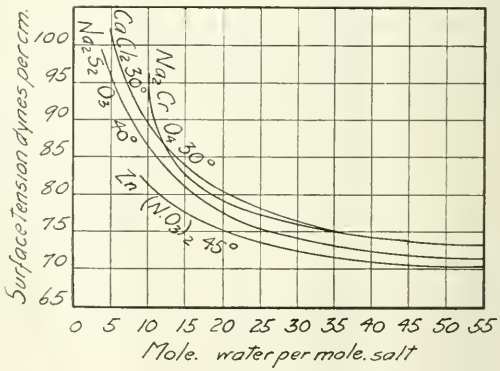

Fig. 2.

It is suggested in these researches that the surface tension of a solution of two salts one of which raises the surface tension and the other lowers it, is an additive property of the two solutions—provided no chemical reaction takes place between them, and the values of the two are not far removed from the value of water. If one of the solutes causes a much larger effect than the other, the value of the mixture lies closer to the one with the greater effect.

Regarding the variation of surface tension with temperature, it is made clear that surface tension increases with decrease in temperature.

In reviewing the subject of flotation in one of the mining journals about two years ago, a leading educator made the statement that heat increases surface tension. Now this is absolutely erroneous in case of pure water and it is not likely that it would maintain in any case. I do not mention this in a fault-finding spirit, but to show that in the science of flotation the metallurgical engineer faces problems in physics and chemistry that are absolutely new to him.

In the work in the chemical journals the surface tension of pure water is taken as 71.03 dynes per cm. at 30°, 69.33 at 40°, and 68.46 at 45°, while Hoover† uses 81 with apologies. Again Hoover makes a slip on page 77 where he says that surface tension of water has been determined to be a force of 81 dynes per square centimetre. Here he has confused surface tension in dynes per centimetre with surface energy in "ergs per sq. cm." Work (in ergs) is the act of producing a change in opposition to a force (in dynes) that resists this change. Now, gravity gives to a gram a velocity of 980 cm. per second. It is therefore equal to 980 dynes. Hence if one gram be lifted vertically one centimetre, the work done against gravity is 980 ergs. Books on physics‡ demonstrate that surface tension (dynes) per unit-width is numerically equal to surface energy (ergs) per unit-area. We should therefore speak of surface tension in dynes per centimetre, and surface energy in ergs, per square centimetre.

The above figures on surface tension and surface energy might be applied to the so-called surface tension method of flotation, such as the Wood machine, where the ore is fed dry onto the surface of water and at one place at least, in the West, where the wet oiled pulp is spread upon the surface of water in a spitzkasten.

While 0.0724 gm. (71.03÷981) per sq. cm. represents the weight that it requires to just break the surface membrane of pure water, there is another factor, and that is the size of the dimple formed. Take the case of galena. The buoyant factors are the membrane and the water displaced. Taking the specific gravity of galena at 7.5, the maximum volume of a dimple on one square centimetre would be 0.0096 cc. (0.0724÷7.5) or a displacement equal to 0.0096 gm. water. Adding the two quotients we find that 0.082 (0.0724+0.0096) gm. galena per sq. cm. would just break through. This is not mathematically correct, but a close approximation—sufficiently close, because we do not know the volume of the foreign water attached and the condition of the water.

Hoisting Works in the Park City District, Utah—I

By L. O. HOWARD

The second of the large modern hoists to go into commission in the Park City district was that of the Daly West Mining Co. The surface plant of this company is situated around the main shaft in Empire canyon, two miles southwest of Park City, at an elevation of 8400 ft. The shaft is 2100 ft. deep. It has two hoisting-compartments, each 4 ft. 6 in. by 5 ft., and a small pump-and-ladder compartment. Second-class ore and waste are hoisted to the surface, and sent to the mill and dump respectively. First-class ore is hoisted or lowered to the 1200-ft. level and hauled 2½ miles through the Ontario adit to loading-bins at Park City. Concentrate is also lowered in cars on cages to the same level. During the summer months men and timbers are lowered from the surface. When the roads become impassable supplies are brought into the mine through the Ontario adit.

Late in December 1913 all the mining plant and mill of the Daly West was destroyed by fire. Shaft-house, hoist-house, boiler-room, and mill were either connected buildings, or in proximity to each other. As may be seen in the illustration of the surface plant, these structures are now separate, even the hoisting-engine being some distance from the shaft-house. The old hoist was a Bullock flat-rope and reel type, hoisting two triple-deck cages in balance. The head-frame was wood, 80 ft. high. The compressor was an Ingersoll-Sergeant two-stage, duplex, steam-driven type, compressing to 100 lb. per square inch, and displacing 2200 cu. ft. of free air per minute.

It is interesting to note that whereas the two other modern hoists in the district are of the flat-rope and reel type, and whereas the old Daly West plant was also of that type, the new hoist is equipped with double-drums and round rope.

This hoist differs from the others in the district. It is a Wellman-Seaver-Morgan double-drum type electrically driven through herring-bone gearing. The principal data concerning it are as follows:

Working load, about 15,000 pounds.
Diameter of drums, 60 inches.
Face of drums, 39 inches.
Capacity of drum, 2400 ft. of 1-in. round rope.
Rope, Roebling, 8-strand, 17-wire, 1-inch.
Diameter of drum-shaft, 8 inches.
Size of bearings, 8 by 14 inches.
Diameter of clutch, 60 inches.
Brakes, parallel-acting post-type brake-ring, 80. in. diameter.
Rope-speed, 1000 ft. per minute.
Capacity of skips, 4 tons.
Clutches and brakes are actuated by compressed air.

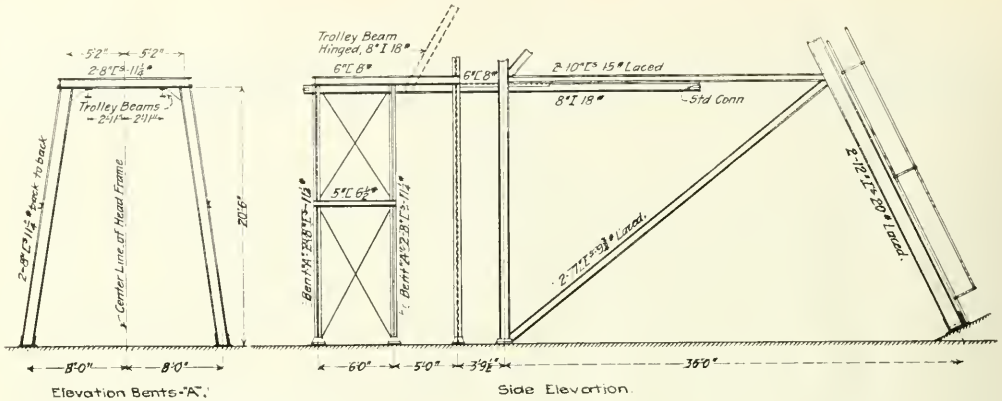
A steel head-frame has replaced the old wooden one. Its principal dimensions are:

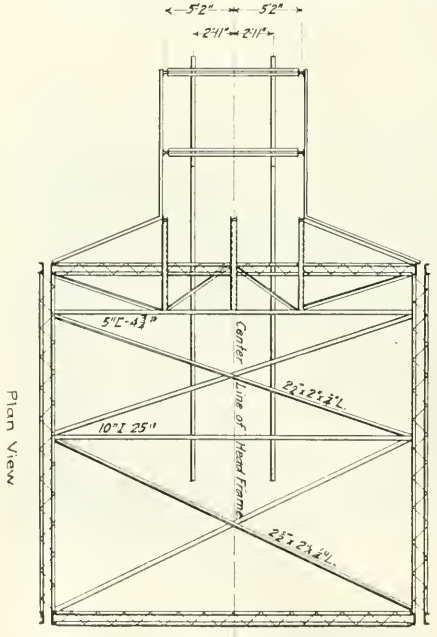
FIG. 1. VIEW OF HOIST-HOUSE AND HEAD-FRAME AT DALY WEST MINE, WITH RUINS OF THE OLD PLANT IN THE FOREGROUND.

Height from foundation to centre of sheave, 75 feet.
Width of tower, 32 feet.
Spread of tower, 36 feet.
Diameter of sheave, 7 feet.

The motor is a Westinghouse, type CI. It takes current at 2200 volts, 3-phase, 60 cycles, delivering 300 hp. at 500 r.p.m. Speed-control is by liquid rheostat. The following description of the construction and operation of the rheostat is taken from a leaflet issued by the manufacturer.

"The three secondary phases of the motor are each connected to a set of electrodes which are rigidly suspended in a tank; each set is insulated from the others. A liquid is pumped into this tank from a reservoir below by a small motor-driven pump and flows over a weir in the electrode tank back into the reservoir. The position of the weir determines the height of the level of the





PLAN AND ELEVATION OF THE DALY WEST HOIST-BUILDING.

Moving the lever in one direction closes the proper primary switches for starting the motor forward and raises the weir. Moving the lever in the opposite direction, reverses the motor and again raises the weir. Speed control is secured by varying the position of the weir by moving the lever; the primary switches do not open

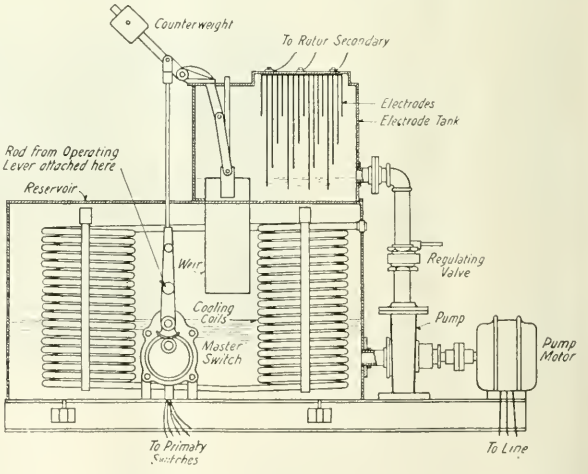


DIAGRAM OF CONSTRUCTION OF LIQUID RHEOSTAT.

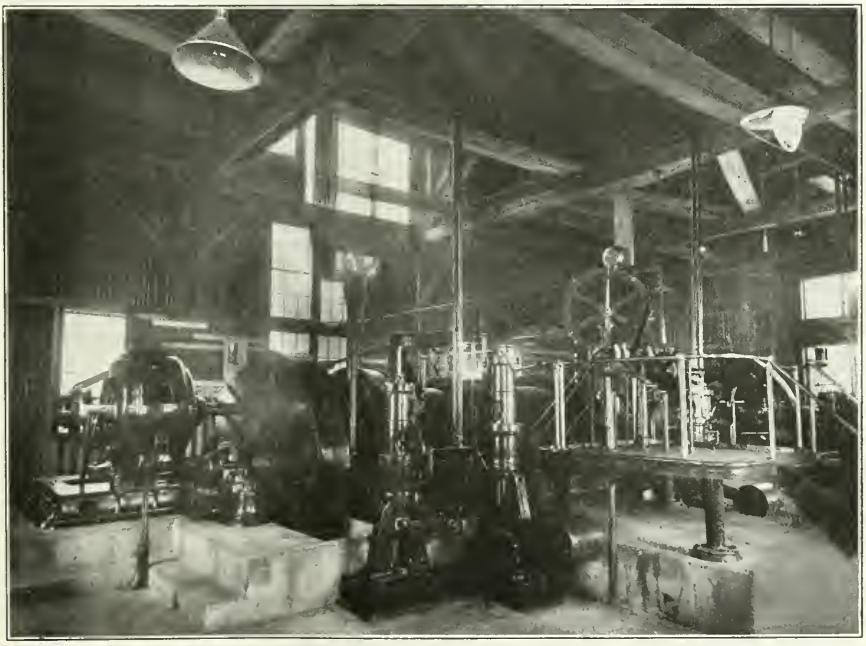
liquid in the electrode tank; the higher the level, the deeper the electrodes are immersed, and the lower the resistance. Hence, by changing the position of the weir the resistance in the motor secondary circuit is decreased or increased, depending upon whether the weir is raised or lowered, and a corresponding change in the speed of the motor is obtained. The primary circuit of the motor is opened and closed by means of electrically operated switches, which are controlled by a master switch mounted on the rheostat. The operating lever of the rheostat controls both the master switch and the weir. When the lever is in its central, or off, position, the primary switches are open and the weir at its lowest level, so that the secondary resistance is maximum. until the lever is placed in the off position. A valve in the intake pipe of the electrode tank regulates the rate at which the liquid is pumped in, so that no matter how quickly the operating lever is moved, the liquid can only rise at the rate for which the valve is adjusted, thus fixing the rate of acceleration. When the lever is returned to the off position, the weir drops and the liquid level promptly falls. The electrodes are rectangular iron plates. Each set consists of plates of different lengths so that the resistance decreases very rapidly as the liquid rises. The tanks are made of welded-iron plates. The reservoir contains coils through which cool water is circulated which prevents the rapid evaporation of the liquid. The weir is a cylinder with open ends. The

liquid pressure against it is equal on all sides so that the weir is easily raised and lowered."

Second-class ore is hoisted in skips dumping into bins in the head-frame. Men and timbers are lowered on two double-deck cages. The arrangements for changing from skip to cage or from cage to skip, familiar enough in the Michigan copper country, are rather unusual in Western practice, which seems to favor separate man-cages, operated by their own hoists. They are not, I believe, used elsewhere in Utah. Let us assume that ore is being hoisted and that it is desired to change to the cages: The cages are hung from trolleys traveling on the track-beams. Five men make the change, three working above and two at the shaft-collar. The operation is carried out as follows: The four hinged track-beams are thrown down over the shaft, filling the gap in the trolley-track. The guides are at the same time thrown back on hinges closed. The cage is then ready for use. The operation is next repeated with the other skip and cage.

The following cycle was timed by me under normal operating conditions involving no need of haste.

	Minutes.
Dropping trolley-track, placing platform, throwing out guides and hoisting skip	1
Attaching trolley-hook, slacking and detaching cable, swinging skip out of shaft	1
Pushing cage over shaft	½
Attaching cable, detaching trolley-hook	½
Lowering cage, throwing trolley-track back, removing platform, throwing in guides, and closing hood	1
Time changing one skip to cage	4
Bringing up second skip and carrying out similar operations	5¼
Total elapsed time	9¼



INTERIOR OF DALY WEST HOIST-ROOM.

Showing hoist-motor, gear-case, drums, operating platform, and brake mechanism.

and the skip-trolley run over the shaft. The skip is hoisted, platforms placed over the shaft-opening, the trolley-hook fixed, a rope attached to the cable, the clevis opened and the rope pulled out of the way. The skip on its trolley is then pushed back from the shaft upon its storage-track, and the cage-trolley is run out from the opposite side of the shaft into position in the head-frame. The hoisting-rope is attached and the trolley-hook disengaged and pushed back on its track. The cage is lowered slowly below the collar of the shaft, the portion of the trolley-track over the shaft is thrown back, the guides swung into place and locked, and the hood of the cage

The time consumed in making the change from skips to cages depends largely upon the hoist-engineer, all operations not involving the operation of the hoist being performed quickly.

Additional equipment in the hoist-house includes a Laidlaw-Dunn-Gordon compressor, a new type in this State. The cylinders are 29 by 16 by 24 in. The piston displacement is 2400 cu. ft. of free air per minute, compressing in two stages, to 35 and to 100 lb. respectively. The compressor is direct-connected to a Westinghouse synchronous motor, taking current at 2200 volts, 3-phase, 60 cycles and delivering 450 hp. at 150 r.p.m.

The Valuation of Metal Mines

By T. A. RICKARD

*The present value of a mine is based on an estimate of future profits. The profits are expressed in terms of money. The value of money differs with time and place. While money is unlikely to differ in value notably in the same place during the relatively short life of a mine, it is likely to be affected by the condition of locality. Money is worth less at New York than at Tonopah, for example, the prevailing rate of interest in the one case being 4 or 5% and in the other from 8 to 12% per annum. This difference tends to facilitate the transfer of a mine from an owner in the desert to a capitalist in the city. The latter is content with a smaller return on his "investment," as he is apt to call it. The difference in the point of view tends to promote business; it facilitates the sale of mining property.

In all business transactions the point of view is vital; hence the difference between the valuation of mines for purchase and the appraisal of them for taxation. Attempts have been made to put both kinds of estimation on the same basis. They have failed. The purchaser buys a mine to hold it and to exploit it until it is exhausted; when the purchase is completed, he cannot revise the transaction. If he buys with the idea of reselling, he must do so on the supposition that the next buyer will act intelligently; that is, as a sensible man, the purchaser cannot assume an escape from a blunder by the interposition of somebody more foolish than himself. Such assumptions, it is true, are not uncommon, but they proceed on lines of reasoning outside the limits of an economic investigation. Therefore, I repeat, the purchaser, whether an individual or a company, buys with a view to exploitation. The State, on the other hand, assesses the mining property annually, and is in a position to remedy any error in its estimate from year to year. The first appraisal is not irremediable; therefore it is not so momentous. Nevertheless the State authorities, recognizing the inherent difficulties of the problem and their incapacity to solve them, usually avoid them by simply taxing the output of the preceding year, that is, they prefer to deal with the statistics of actual production. They appear to recognize, or they may have merely surmised, that the ante-mortem diagnosis of a mine is necessarily aberrant. In truth, it is a tricky business. Having regard to the inherent difficulty of estimating future production, it is not surprising that the taxation of output has been adopted in many States as the most practicable method. It seems best for the purposes of annual taxation, even though it may fail to penalize those owners who choose to leave their properties idle in the hope of selling them at a higher price or of exploiting them when the market for their product is more favorable. This evasion can be checked, to some extent, by taxing the claim-area or acreage, whether productive or not, to such a degree as to render long idleness prohibitive.

The appraisal of mining properties for State taxation has had the good effect of drawing public attention to a subject heretofore deemed too recondite for general discussion. Mining engineers, among themselves and in the technical press, have touched upon the problems involved, but, on the whole, the solution of these problems has been deemed in the nature of a professional secret, to be left in the safe-keeping of the individual. The active members of the profession, or practitioners, it may be inferred, consider it impolitic to publish the particular basis on which any one of them might see fit to value a mine for his client. If an engineer were to state beforehand that he could not report favorably unless certain fixed conditions were fulfilled, he might cause sundry vendors to object to having their property subjected to a test so exacting as to render business impracticable, with the further unpleasant consequence of placing a black mark against the name of the mine. Moreover, the criteria to be used in valuing different mines by the same engineer will vary in accordance with the character of the mining and of the client. In some kinds of mining the uncertainties are vastly greater than in others; so also some clients are willing, and can afford, to take bigger risks than others. For reasons of this kind the scheme of valuation is rarely set down in black and white, not even for professional information, much less for public enlightenment.

Within recent years, however, the State of Michigan engaged a mining engineer of acknowledged repute, Mr. J. R. Finlay, to make an appraisal* of its mining properties for purposes of taxation. Other State Commissioners had tried to perform the same task under the guidance of politicians, labor-leaders, geologists, and various gentlemen distinguished by varying lack of fitness for the task. In this respect they were like the lay public, which is learning slowly and painfully that the only person likely to value a mine successfully is a mining engineer equipped with the requisite training and experience. It is fair to add, however, that the State of Wisconsin deputed the study of mine valuation and assessment in its zinc-producing territory to a member of its Geological Survey, namely, Mr. W. L. Uglow, whose report† gives the impression that he also, although

*A paper presented before the International Engineering Congress, San Francisco, 1915.

*'Appraisal of Mining Properties of Michigan,' by the State Board of Tax Commissioners, 1911.

†'A Study of Methods of Mine Valuation and Assessment,' Wisconsin Geological and Natural History Survey, 1914.

probably less versed in the management of mines, has envisaged the subject with convincing skill.

The official reports issued as a sequel to the investigations made by Messrs. Finlay and Uglow furnish an excellent text for a general discussion of the subject. Mr. Finlay states that his appraisal is "a calculation of the value of mines to the permanent owner for the production of minerals." The value of a mine for share-market purposes is ignored; so is its value for the purpose of re-sale. Neither aspect of the problem came within the province of his enquiry. The appraisal is based on three factors:

1. The average cost of production.
2. The average price obtained for the product.
3. The future life of the mine.

The first two are determined "by experience," that is, they can be ascertained by investigating the records of the mine and of the industry, with sagacious inferences therefrom. The third factor is "based partly on developed ore and partly upon an assumption of continuance of known orebodies beyond the present bottom levels of the mines."

From these three factors the future net profits, or dividends, are calculated. The present value of such dividends is then reduced by the annuity method to a sum upon which they will pay a given interest and at the same time provide an annual contribution into a sinking fund, which, re-invested, and added to prior installments similarly invested and re-invested, will redeem that sum within the period covered by the life of the mine. Mr. Finlay took 5% as the dividend interest and 4% as the rate of amortization. This may be accepted as adequate for the particular, and relatively safe, type of mining illustrated by the copper and iron deposits of Michigan, but in precious-metal mining, which is more hazardous, the rate of dividend should be at least 10%, with the possible exception of a few orebodies of extraordinary uniformity.

This method, of course, ignores unprofitable mines. It is also inapplicable to prospects. On the other hand, the mere discovery of mineral on land may give it an immediate and taxable value, to be determined on a different basis, as is shown in Mr. Finlay's report. In the productive copper mines he had a relatively simple problem. For instance, in the case of the Wolverine, the records showed that during the preceding five years the necessary data were as follows:

Yield of copper per ton of ore	26.7 lb.
Cost of producing copper per pound	7.65c.
Average price of copper per pound	15.60c.
Profit during the 5 years	$3,896,270
Estimated total future production of copper in pounds	80,000,000
Valuation of the mine	$3,700,000

The Wolverine orebody represents an enriched portion of the Kearsarge lode, which consists of a layer of amygdaloidal diabase impregnated with native copper. The lode has a fairly regular dip of 40° and has been traced on its strike for 5 miles through a series of most productive mines. Mr. Finlay assumed, or "calculated with certainty," that part of the Kearsarge lode will continue profitable to at least 6000 ft. in depth and that 60% of the lode-area within the known profitable length will be mined to that great depth, yielding an average of 16 lb. copper per ton. On this basis the lode would yield 70,000,000 tons of ore, in addition to the 20,000,000 already mined. And of the grand total he credits the Wolverine with 3,600,000 tons. He gets at this by taking the surface area covering the lode on its dip at 215 acres, and the thickness of ore at 12 ft.—for the stoping-width is remarkably regular. Estimating that the reserve of ore will last for 9 years, that the copper can be won at 8 cents per pound, leaving a profit (on a 14c. price) of 6 cents per pound, he obtains a total profit of $4,800,000 and a present value of $3,700,000.

In appraising the copper mines of Michigan, Mr. Finlay had no trouble in obtaining accurate data in regard to cost, for the books of the companies operating the mines were open to him. These companies are old and respectable; the technical management is first-class; any information required by an accredited investigator is given willingly and accurately. Mr. Finlay could have had no trouble in ascertaining the total cost per pound of copper. Then he had to make an estimate of the probable price of copper during the future life of the mines under appraisal. He decided that 14 cents would be fair, although personally inclined to believe that this was low. That was in August 1911. Since then the price of Lake copper has been as follows:

Year.	Average.
1911	12.63
1912	16.56
1913	15.70
1914	13.61

His estimate needs no apology. He was making an appraisal for annual taxation; presumably therefore the valuations of the various mines could be reviewed from year to year and corrected in accordance with the rise or fall in the price of copper. If he had been valuing the mines for a purchaser, he would, by taking 14 cents as an average price, have been no more conservative than we should reasonably expect an engineer to be under such circumstances. In short, he is justified in the result.

As regards the life of the mines, Mr. Finlay could make no personal examination in the time at his disposal: he had to examine the records, with maps and sections, assisted by the willing information of the managers. On this he could rely to a degree not usual in the examination of mines in private practice. The copper mines of Michigan are well developed, the character of the orebodies is well understood, the relative persistence of the ore has been ascertained. Indeed, the non-persistence beyond a known horizon helps the appraiser, who is not called upon, as in some regions, to give serious thought to dreams of unlimited continuity in depth. The length of ore likely to be extracted is, in most cases, determined either by the boundaries of adjoining properties or by exploratory work, for the intelligent mine-operator endeavors to ascertain these fundamental facts as soon as

possible, in order to plan intelligently and to equip providently. Therefore I conclude that Mr. Finlay's estimates of 'life' were so correct as to afford a safe basis for the appraisal required by the Tax Commission.

Turning to the similar effort at scientific valuation in Wisconsin, two years later, it will be found that Mr. W. L. Uglow was instructed by law to assess mineral land at the "full cash value" it would bring "at private sale." This was understood to mean "a sum of money which engineers and business men would be willing to pay for a property if they should have full knowledge of all the facts of past production and future prospects at their command." The lack of "full knowledge" in regard to future production is, of course, the crux of the whole matter; indeed, it is the one awkward factor, and for that reason it is usually pushed into an obscure background.

Conditions in Wisconsin are relatively simple. The owners of the land are mostly farmers, who lease the ore-bearing areas to mining companies. The latter test the ground by churn-drilling and then sink their shafts, preparatory to extracting the ore, which lies at a shallow depth, the maximum being about 250 feet below the surface. A royalty of about 10% on the gross output is paid the owner as his rent or share of the earnings. He pays the real-property tax, as well as an income-tax on his rent. The orebodies have their greatest dimension horizontally; about 10% of the crude ore is left as pillars; the ore consists of blende, galena, and pyrite disseminated in limestone; it is subjected to concentration, the concentrate being sold to the smelting companies. The properties are small, for the shallowness of the deposits does not compel concerted effort or big capital expenditure.

In order to get at a reasonable basis for valuing the zinc mines of Wisconsin, Mr. Uglow takes a "hypothetical zinc mine," built upon the figures obtained from eight properties; these figures in turn he reduces to weighted averages over a period of four years. This four-year life is assumed on the basis of local experience. Of course, a whole lot of other assumptions have to be made, such as the price of spelter, which is put down as 5.7, 5.4, 5.0, and 5.5 cents per pound for the four years respectively, although it is not clear why the guess should not be made uniform. Apart from the fact that the price of zinc is beyond the vaticination of any appraiser of mines, it is noteworthy that in the last stage of his valuation Mr. Uglow deducts 15% "on account of the absence of data for checking the assumed figures for grades of ore." If 15%, why not 51%?

Having constructed this hypothetical mine, Mr. Uglow applies it to ground "well drilled" and ground "poorly drilled at the outset." The present value in the one case is $168,117 and in the other $125,180 at the beginning of the first year.

Next he applies various systems of valuation to this hypothetical mine and arrives at the conclusion that the most suitable method for the zinc mines of Wisconsin is that of equated income. To ascertain the value of a mine, therefore, he multiplies the annual operating profit by 2.43, this factor having been determined by mathematical analyses on the assumption of equal annual profits and an average life of 4 years. He concludes that, as compared with the *ad valorem* method, this scheme has the advantage of being based on the estimated average life of all the mines, not a particular one, in the district; it is calculated on the actual profit of the preceding year, not upon an estimate of future profit; moreover, it is well adapted to taxation because it assesses a mine in accordance with its ability to pay, rather than its sale-value.[2]

Again we face the fact that the valuation of a mine for purchase and its assessment for taxation constitute two different problems. The tax-gatherer's valuation is made annually, and can be revised annually, therefore it is convenient to base it upon the actual profit—not production—of the previous year. The future does not concern the tax-gatherer; he takes short views of life; it is his duty annually to collect a contribution to the revenue of the State in equitable proportion.

We shall leave him to his troubles, which are relatively small, for it is our purpose to discuss the valuation of mines for sale or purchase, which is a far more difficult problem.

In order to value a mine, that is, to determine the price at which it is a reasonable purchase, it is necessary to estimate its future profits. That is done in successive steps, ascertaining:

1. The average yield per ton of ore.
2. The average cost per ton of ore.
   (The difference between 1 and 2 is the 'profit.')
3. The tonnage available now.
4. The tonnage likely to be available in future years.

Each step demands skill and experience. The yield is determined by a careful sampling of the ore exposed in the workings, by comparison with past records, and by an estimation of the probable extraction in the mill or smelter. The metal contents as determined by assay do not represent the yield; to ascertain that it is necessary to know the percentage of extraction by the metallurgical method most suitable. Mines are bought sometimes on the expectation of applying increased skill to the extraction of the metals from the ore. The expectation may prove too flattering.

The average cost can be ascertained from past records, with corrections based upon any anticipated change of conditions. The anticipations may prove fallacious. The records may be deceptive. 'Cost' is interpreted variously. Among British-owned mines, particularly in Rhodesia and West Africa, it is customary to give a figure for 'cost' that omits many inevitable items of expense, such as head-office expenses, taxes, insurance, depreciation, improvements, recruiting for labor, even development and prospecting. In some cases the omissions represent discrepancies of 30 to 40% from the actual cost, giving phantom profits highly useful for share-market purposes. The big mines of the Rand

[2] 'Method of Mine Valuation and Assessment,' by W. L. Uglow, page 68.

issue monthly figures of profits that are illusory because in the cost the Transvaal profit-tax is omitted, together with London expenses, income-tax, debenture interest, and additional expenditure on new equipment. The result is that the profits periodically announced are 30% more than the dividends. I have always argued[3] that the profit to the shareholders, who are the owners of a mine as conducted on the joint-stock principle, is represented by the dividends that actually get into their pockets or are lodged to their bank-accounts. To many persons some of the items, such as interest and taxes, seem beside the mark. The borrowing of money on debentures, however, usually represents a miscalculation in the original estimate of initial expenditure for development and equipment. As for income-tax, it may be said that it is only a matter of book-keeping, since the collection at the source obviates later payment by the shareholder. But the income-tax on a mine is a true (and most inequitable) item of cost, for in most cases it is a tax not on income but on the return of capital. Until a mine has redeemed its purchase price, its dividends are not income. A mine is a wasting asset.

Many blunders in valuation are made by engineers owing to lack of knowledge concerning the 'overhead' expenses. Any sagacious appraiser of a mine that is to be placed on the London market, and managed from there, should add from 10 to 20%, according to tonnage of production, to his operating or local cost, if he expects to make a forecast that will stand the test of future accomplishment. Indeed, the best school for the appraiser is last year's almanac; let him read the old reports and valuations of mines now approaching exhaustion. He will see how errors were made and how estimates were falsified. For example, the small additions to equipment made from year to year may seem a minor item. No allowance usually is made for re-building or replacing the existing reduction works, yet no mill or smelter remains intact for many years, if the owners are progressive. Fires and other accidents will happen. Decay and destruction, wear and tear, are inseparable from machinery and equipment. For example, the cost of new equipment at the Bunker Hill & Sullivan mine, in Idaho, averaged 80 cents per ton during 22 years, on a total operating cost of $2.66 per ton.[4] Again, when I examined the Camp Bird mine in 1900 I found that Thomas F. Walsh, the owner, had extracted $2,535,000 worth of ore at a cost of $6.50 per ton. I estimated the ore assured at $6,000,000 and anticipated that the cost could be reduced to $5.25, in consequence of an improved equipment and larger tonnage of production. The mine more than fulfilled the expectations of productivity and profit, but the average cost was $10 per ton. The administration and general expenses of a London company proved more costly than I had anticipated, in comparison with the thrifty management of an individual owner. The reading of old reports shows that a post-mortem will give data more reliable than those obtainable from a diagnosis made while the patient is alive; unfortunately, old reports disappear, to the comfort of the profession, and exhausted mines cease to be interesting, except to the historian; therefore this source of guidance is not readily available to the student of the subject under discussion.

Turning to the question of tonnage. The ore exposed can be measured and an estimate of that which is partly exposed can be made with reasonable accuracy by an experienced engineer, that is, by one wise to the vagaries of various types of ore deposit. When, however, the next step is taken, namely, the estimation of ore likely to be rendered available in future years, as the result of intelligent development and exploration, the engineer faces a crucial problem and one that may render all his previous ratiocinations utterly futile. The test of science is prediction; the inability of the mining engineer to predict the continuity of an orebody suggests that the appraisal of mines is not a science, but an approximation based upon empiricism.

Attempts have been made to express the probabilities of ore-persistence by formulae. Some engineers allow for future prospects by adding a fixed proportion—from 20 to 35%, for example—to the ore already proved. Such short cuts are illogical. They constitute a mere surmise. Mr. H. C. Hoover has suggested that "the minimum extension of an orebody or ore-shoot in depth below any horizon would be a distance represented by a radius equal to one-half its length."[5] This may apply to his special experience in Western Australia, but it is dangerous doctrine, for, as he himself adds: "This is not proposed as a formula giving the total amount of extension in depth, but as a sort of yardstick which has experience behind it." Another writer, with less experience and therefore greater positiveness, has offered sundry elaborate formulae[6] for the purpose of expressing the probabilities of ore-extension in depth. These, apart from their academic interest, are interesting as indicating how many uncertain factors are involved in the calculation. They are useful as suggesting a line of reasoning, based upon the length and thickness of the ore-shoot, the number of levels already proved, and the patchiness of the lode within the ore-shoot. Indeed the methods of an actuary may be illuminating to an engineer, but the latter must realize that human life has been studied much longer than the distribution of ore underground, and that the eccentricities of human nature are better understood than the vagaries of ore deposition. Calculations based on a large number of guesses can only yield a guess. The doctrine of probabilities has been stultified in mining too often to allow of its being stated as a scientific thesis.

Having ascertained the tonnage of ore in the mine and the probable profit per ton, the engineer can say that the ore assured will yield so much money, while the ore likely to be uncovered will enable so much more

money to be taken out of the mine in future years. How much then is the property worth?

While the estimation of ore in most mines is hazardous, especially in the case of rich precious-metal veins or lodes, it is a pleasant fact that in certain types of deposits the size and continuity of the orebodies are such as to minimize the variation of metal-contents to the point of relative uniformity of production over long periods. This is true, or has been true for many years consecutively, of the native-copper lodes of Michigan, the gold-banket of the Witwatersrand, the gold-bearing schist of the Homestake, the copper-pyrite lenses of Huelva, and the extensive chalcocite impregnations of Nevada, Utah, and Arizona. However, even in these cases, it must be confessed that, for purposes of appraisal, the knowledge now available has come at a late date; it has come in the wake of experience, not as the result of preliminary investigation. Moreover, it is not applicable to other mines in other regions, save at great risk. Most young mines—and it is young mines we must appraise, as it is young people that we must insure—cannot be judged on the basis of experience on the Rand or in Michigan. That is why engineers with local experience in particular districts so often fail in diagnosing mines in other districts.

We return to the question: what is a mine worth, given an estimate of future profits? We have seen Mr. Finlay's formula, based on 5% for interest and 4% for amortization. I have said that his return of 5% might do in the case of the copper and iron mines of Michigan, but it was too low for most mining enterprises. Mr. Hoover says that "the mining business is one where 7% above provision for capital return is an absolute minimum demanded by the risks inherent in mines, even where the profit in sight gives warranty of the return of capital."[7] With this, of course, I agree. Indeed, in most precious-metal mines 10% is not too much. On the other hand, no figure can be stated as generally applicable. It depends upon the factor of risk, which varies in each case, not only as regards the continuity of the ore, but the capacity and honesty of the management. This feature of the problem has been well elucidated by Mr. Burnham,[8] who asks, and answers, the question as to how much a mine ought to pay over the standard rate of interest on gilt-edged stock. Besides the addition to cover "the yearly contribution for capital redemption," he insists that provision be made for "the risk of loss of either capital or interest." Thus by the time the engineer has made his estimate of the value of ore assured and the profit therefrom, he finds his figures blown into the air by this explosion from under his very feet. These final considerations regarding the rate of return on the purchase price of the mine afford divergencies so big that all the little refinements of measuring, sampling, and assaying are rendered pitifully inconsequent. If we take the standard rate of interest on national bonds as 3% and if we add to this another 4% for capital redemption, we are brought face to face with the decision as to what further percentage must be made to provide for the risk inherent in mining and the final risk involved in a particular mine. Suppose we agree on the third item of our enquiry and call it 3%, even then we have the fourth item to ascertain— and it is by far the most momentous in the whole of our enquiry. It may range from 0 to 100%.

Let me illustrate. Many years ago I examined a small silver mine in Boulder county, Colorado. The vein was narrow but rich. The ore-bearing ground was sampled thoroughly. The result was to show that $150,000 worth of ore could be extracted at a cost of $40,000, working through an existing adit, so that $110,000 could be earned. The owners were willing to sell for that sum, half cash and half in six months. The winzes below the bottom level or adit showed that the vein was poor and broken by faults. The prospects in depth seemed to me slim. I considered it a poor purchase, because the risk of the known ore yielding less than the amount estimated outweighed the probability of finding more ore in virgin ground. Even 100% per annum—that is, the return of the purchase price in one year, as was feasible in this case—was not good enough. The later story of the mine justified this decision.

In a recognized guide to these matters, namely, the "Report Book for Mining Engineers," by A. G. Charleton, an example of mine valuation is given. In this hypothetical case the property contains 704,000 tons of ore averaging $12 in gold per ton, making $8,448,000. Allowing for a recovery of $10 and a cost of $7.50 per ton, the profit comes to $2,464,000. The conditions specified are (1) that the above profit is to be won over a period of 11 years, (2) the plant and equipment are to cost $183,700, and to this is to be added compound interest for two years at 5% during the time of development precedent to profitable production, (3) the capital is to be redeemed at 2½%, and (4) the purchaser is to be allowed 20% on his money. Therefore the present value is $290,000. As if this were not drastic enough, Mr. Charleton shows that on a 40% return the present value would be $4. This *reductio ad absurdum* shows where these methods of valuation land. After taking great pains to sample the ore and equal trouble to ascertain the profitable metallurgical recovery, after having inquired thoroughly into the question of cost and made several solemn guesses at the persistence of the ore—having solved these preliminary problems, the engineer is to choose between 5, 10, 20, or even 40% as the rate of return required to justify the 'investment.'

The elaboration of any calculation should be proportioned to the possible accuracy of the factors involved. Otherwise it fares no better than the New Jersey farmer's method of weighing sheep. The animal is attached to one end of a fence-rail while a bag of stones is attached to the other end. First the exact centre of the unloaded rail is ascertained, then the sheep and the bag of stones are fastened at an exactly equal distance from the centre, or fulcrum, and a perfect balance is obtained. When all this has been done with painstaking care, the bag is emptied on a clear bit of ground and the weight

[7] *Op. cit.*, page 43.

[8] *The Mining Magazine*, May 1911, pp. 361-363.

of the stones is guessed. Why not guess at the weight of the sheep in the first instance?

Obviously, therefore, mines are not to be appraised on the basis of an investment. Whether iron or coal mines are so different from those yielding the precious metals, or copper, lead, and zinc, as to warrant a different treatment, I leave it for others to state. My own experience has been chiefly in gold and silver mining. In the case of gold, one factor, namely, the market price of the metal, is eliminated. Just now the price of the base metals is subject to abnormal fluctuations, but even in peaceful times this element of uncertainty is an essential part of the business. Some of the bigger copper mines have reserves so large and operations so systematic that the perturbing factors are apt to be forgotten. Promoters and brokers speak of such steady producers as "manufacturing propositions," meaning that they are on an enduring basis. This, of course, is balderdash. A mine is a wasting asset. It has no goodwill; that exists in the management and is transferable to another mine, but it does not ensure the life of a particular property. The resources of a mine are not renewed; at some stage in its history they are underestimated and conjectural, but that does not mean that they are increased; they are merely uncovered. The art of mining cannot be applied on scientific principles until two basic ideas are fully comprehended:

(1) A mine is a wasting asset.

(2) Mining is a speculative business.

To treat a mine as an investment, and to appraise it on that basis, is to ignore the cumulative facts of today and of other days. Mining is a speculation that can be made wise or foolish according as a man recognizes the inherent risk and takes his chances accordingly. As a speculation it is highly profitable when conducted intelligently. The ascertainable factors are sufficiently numerous to place a premium on trained observation and the inferences therefrom are sufficiently valuable to give an advantage to men of intelligent experience. The unknown and unknowable elements in the problem will remain so numerous and so important as to involve a risk so large, and the chance of a winning so big as to stimulate the adventurous spirit of man.

Unusual Mine Accident in Tennessee. An old diamond-drill hole was used for breaking rock by first placing an old ladder-rung in the hole to act as a backing and then loading the powder and tamping on top of it. After spitting the fuse the miner retired through an S-shaped passage to a place about 125 ft. away and thought he was perfectly safe. It happened, however, that he stopped exactly opposite the distant end of the very diamond drill-hole in which the charge had been set. When the shot went off the backing blew out underneath the dynamite and a considerable part of the force of the shot was transmitted through the hole as through a long gun-barrel. Small fragments of rock were discharged against his back, so that he was badly injured.

The Britannia Copper Mine

*British Columbia claims the largest copper mine in the British Empire, the Britannia mine on Howe Sound 25 miles north of Vancouver. The plant when finished will treat 4000 tons of ore per day. The ore contains 3% copper and a little silver; it is estimated to be worth $8 to $10 per ton. Development by adits, shafts, and levels indicates several million tons of ore at Britannia Mountain, 3.8 miles from the beach and outcropping at an altitude of 3500 ft. An aerial tramway 13,000 ft. long and of 1000 tons daily capacity is carrying the ore to the mill; incidentally, the force of gravity of the descending buckets is utilized to operate an air-compressor at the mine, and the tramway has also been used to transport machinery and supplies. This tramway will continue in operation after the electric railway system is completed. A 30° inclined railway a mile long now under construction (at a cost of $140,000 per mile) will deliver ore to the mill. In addition there will be an electric railway 3½ miles long of 3% grade.

Two years ago construction of a new mill was begun near the present mill on the slope of Britannia Mountain where benches have been terraced out of rock to allow a gravity system. Concentration will be by Hancock jigs and tables, the slime going to a Minerals Separation plant. The tube-mills are 7 ft. diam. by 12 ft. long. A 1000-ft. tunnel under the mill will transport concentrates over the electric railway to the docks for shipment to the smelter at Tacoma.

Records show a production from the mine of $8,582,000 since 1905. The 'Copper Handbook' says: "The Britannia proved a hard problem to handle for years, but made money in 1911 and 1912." G. B. Schley of New York promoted the enterprise, after others had failed. The varied history of the mine since its accidental discovery in 1888 and its second discovery in 1898 has shown the necessity for large-scale operation. Fully $6,000,000 has been expended on the purchase of properties, equipment, timber, and water-rights; of this $2,000,000 was derived from profit through ore shipments. An additional $1,000,000 has just been placed at the disposal of the management. It is hoped that the costs will be reduced to 50 cents per ton for mining, 35 cents for milling, and 5 cents for transportation. Optimistic predictions are made that copper can be produced for 8 cents per pound. At present the British government is taking the output for manufacturing munitions. At least 1000 men will be employed. A hydro-electric plant of 5000 hp. is being erected, but auxiliary steam-power of an additional 5000 hp. will also be required.

It is hoped that this modern development of low-grade ore by exponents of big business will give encouragement for the financing of other prospects of British Columbia's undoubted mineral wealth. Credit is due to the men who have persevered in the effort that has made the Britannia mine a reality.

---

Mining in Colorado

By GEORGE J. BANCROFT

Recent developments in Colorado are as hard to report as the progress of a line-bucking football team. There are few sensational 'end runs' or 'forward passes.' The progress is steady and irresistible, but very difficult to tell about. Even the busy local reporter misses the news. For instance, I met a man from a certain camp in Colorado today and he told me of a mine that has gradually increased its production of a certain rare metal until now it is shipping 100 tons daily of high-grade ore. I have diligently searched the files of the local paper and find not a single record of this fact. I mention this incident because it is so typical of present progress in Colorado. In the good old days when the promoter with the big diamond stud in his shirt-front went 'back East' and brought home the 'tub full of kale' and opened up the mine with the aid of the 'ne'er-do-well' son of the plutocratic president and the artful advice of the high-salaried machinery salesman, there were some easy gleanings for the lords of publicity, but when Tom, the 'leaser,' and Bill, the grocer, and Frank, the saloonkeeper, 'chip in' to open up an old mine, you can never tell, from the outward aspect of things, whether they are crushing the dump to macadamize a road or straining the elastic limit of the bullion vault of the local bank.

So it is with mining progress in Colorado this year. The mining supply-houses never did a bigger business. More powder, fuse, and caps have been bought than ever before in the history of the State, but the notable and interesting difference between today and former times is this: Five years ago a few celebrated mines would account for 75% of the mining supplies shipped out of Denver while 25% went to 'leasers' and unknown buyers. Nowadays the percentage is almost reversed, namely, 75% goes to unknown and unheralded buyers who order goods shipped C.O.D. and 25% goes to well-known mines. That the multitudinous unknowns are placing their shots in the right places is shown by the constantly increasing shipments of ore, but the names and addresses of our 1915 mining magnates would be as hard to congregate as a flock of mountain goats.

A discovery that marks the trend of recent events in Cripple Creek is that on Tenderfoot hill. The local press announces the recent large shipments as coming from a new discovery, and, in a measure, this is true, because the present operators have only recently discovered that reduced working costs in the Cripple Creek district permit of the mining of such low-grade ore as exists on Tenderfoot hill. Large bodies of low-grade ore, however, were developed on Tenderfoot hill as far back as 1899, to my personal knowledge, and it is a far more important 'discovery' to find that working costs have gradually been hammered down to a point where these ores are marketable than to find some individual orebody that had hitherto been overlooked.

Ten to fifteen years ago a number of long-tunnel projects were launched in Colorado. Among these may be mentioned the Yak at Leadville, the Smuggler-Union adit at Telluride, the Newhouse Tunnel at Idaho Springs, the Pro Patria at Rico, and the Roosevelt at Cripple Creek. At the time of launching these enterprises there was a good deal of doubt as to their paying qualities and, taken as a class, long tunnels have proved to be very low-

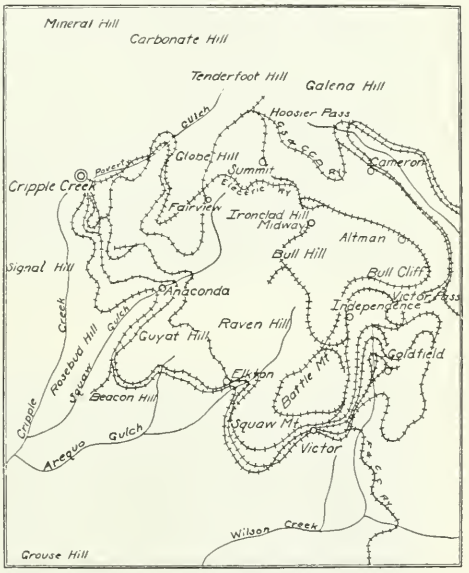
ORE AND METAL PRODUCTION OF COLORADO IN 1914.

dividend earners for the stockholders. It is a fact, nevertheless, that nearly all the great 'tunnel,' or adit, projects in this State have turned out to be great successes so far as stimulating ore production is concerned. Prospecting in wet ground is so discouraging that very little of it is attempted, but prospecting in drained ground is relatively easy, and so it happens that territory drained by an adit receives much more attention than equally good ground that is not so drained. The acquisition of the Alladin group by the Yak Mining, Milling & Tunnel Co. is a case in point. This ground lies near the end of the Yak Tunnel. It is very wet territory and probably would have remained undeveloped for years had it not been drained by the adit. The price named in the lease and bond, namely $600,000, indicates that the Yak people consider the property one of considerable value.

There are many remarkable things connected with the progress of mining in Cripple Creek. One is the geologic form of the deeper ore-shoots and the other is the low working-cost that has been attained in the mining and milling of relatively small ore-shoots of refractory ore. The strange thing about the deeper orebodies is the fact that many of them have no apparent relationship with orebodies nearer the surface in the same locality. It is true that all the deep ore that has thus far been discovered lies under territory that was rich near the surface, but it must be remembered that there are hardly any deep workings except in localities that were very profitable near the surface for the simple reason that no one has had the capital or nerve to prospect any other territory at depth.

In the Vindicator mine the two best levels were at 800 ft. and 1600 ft., but the big stope on the 800-ft. level was nearly 1000 ft. north from the big stope on the 1600-ft. level. Vertically over the big and rich bodies on the 1600 the ground was not particularly good. Vertically below the big rich stopes on the 800-ft. level the ground was not particularly good. On a line connecting the two rich spots the ground was not particularly good. In other words, both of these extremely rich places were isolated. The rich ore on the 1600 was found, for the most part, in veins that are not identified above the 1100-ft. level. In fact, this ore was found in the third horizon or zone of enrichment that occurs in this part of the mine and each zone has its own veins and characteristics, which are distinct from those of the other two. This peculiar condition seems to prevail all over the district. There seems to be no reliable rule for deep prospecting at all. It seems likely, of course, that the deep ore lies approximately underneath territory that was enriched near the surface, but even for this hypothesis there is little evidence. The unusual mineralization of Cripple Creek irresistably inspires speculation as to the geologic causes of it. We know from data collected all over the world that gold mines are closely related to the surface. Very few gold mines extend below 500 ft. from the surface without showing some change. So the first speculation that suggests itself is that Cripple Creek has had several periods of mineralization and that the surface at the time of the first period was buried several hundred feet deep by succeeding lava-flows before the second period began, and so on. The trouble with this speculation is that the granite rim is on a horizon only a few hundred feet below the surface in many places. It does not seem likely that the surface of the ground was ever very far below the granite rim; in other words, it does not seem likely that Cripple Creek was ever a great hole in the ground.

It is devoutly to be wished that we knew enough about the genesis of the Cripple Creek orebodies to direct developments intelligently at great depth. Here is a great chance for an ambitious geologist. It may not be generally known that ore is being mined and milled in Cripple Creek at a cost under $3 per ton. Furthermore



THE CRIPPLE CREEK DISTRICT.

an extraction of about 80% is being effected by cyanide without roasting the ore. For years we have been reading of low working-costs in the exploitation of large deposits of free-milling gold ore, such as the Alaska Treadwell or the Homestake, but I think that very few mining men, ten years ago, would have prophesied that telluride ore, occurring in relatively small orebodies, could be worked for $2.60 per ton, and yet I know of one Cripple Creek mine that is doing this, and I have reason to believe that several of them are actually making a little money on $3 ore. To accomplish such good work it is necessary to use the most scientific methods and to have the very best of men. Cripple Creek is lucky in having some of the brightest men in the industry at the head of her mines and mills and in having a splendid set of workmen.

Preliminary magnetic examination of iron-ore deposits in Minnesota has an important bearing on the situation of subsequent drill-holes.

Igneous Intrusions

By T. A. RICKARD

On the opposite page we reproduce two illustrations obtained by the courtesy of the Director of the U. S. Geological Survey. They appear also in Professional Paper No. 66, as illustrations of the geology of Goldfield, Nevada. We reproduce them because they have a timely interest, in view of recent mining developments in that famous district. The upper picture shows the lower portion of a flow of rhyolite where it penetrates the shale, as exposed in a prospect-hole on the west side of Columbia mountain. The arrows are close to, or point at, the line of contact. The lower photograph shows the same shale (*A*) intruded by a tongue of alaskite (*B*). The alaskite is supposed by F. L. Ransome to have been in a "highly viscous" state at the time of the intrusion, so that "it solidified in contact with the shale before the general movement of the magma had ceased." Here 'magma' is used with reference to the fact that alaskite is a rock representing one of the last silicious phases of differentiation in the consolidation of a granite mass. This was the idea of J. E. Spurr, who likened the Nevada alaskite to the Russian beresite, another quartz-feldspar derivative.

When a granitoid magma consolidates, the silicious remainder (that is, the excess silica left after the formation of such silicates as were competent at the prevailing temperature and pressure and degree of dilution) forms a rock or series of rocks, of which alaskite is a familiar example; and there are also thrown out from the consolidating magma certain silicious solutions that result in the formation of dikes and stringers of quartz in the fractures through which they make their way. Occasionally these solutions contain gold, so that in depositing the quartz they build what is in effect a gold-bearing quartz vein.

Auriferous quartz dikes are sometimes of commercial importance, although commonly they vary erratically from zero to high value, as shown by assays of samples taken at different points on the same deposit. This generally renders them unprofitable. The gold in these dikes has a tendency to develop isolated widely-separated masses or aggregations of particles of the precious metal in the quartz, or to concentrate with iron minerals in vugs, or geodes, preferably occurring on the walls or along comby partings occupying a more or less central position longitudinally through the dike. In general, it may be said, quartz dikes are untrustworthy as a source of gold unless subsequent movement has produced conditions favoring the formation of true veins. That is, as distinguished from dikes. The latter are formed by the filling of a fracture with foreign material, which, when injected, does not react with the enclosing rock save as to the changes due to contact metamorphism. The 'true' vein, however, represents the product of reactions involving a predominance of chemical interchange between the invading solutions and the material of the invaded rock. Since any dike may be a line of later weakness, and since quartz dikes are frequently of great longitudinal extent and but feebly adherent to their bounding walls, they are apt to determine the course of subsequent faults, through which mineralizing solutions may circulate. Owing to the peculiar character of these ultimate silicious magmatic differentiates, in which the silica is supposed to exist free in a colloidal state, they seem incapable of exerting the chemical effects recognized as interchange or 'metasomasis.' In other words, they do not produce a new set of vein-minerals by a process of chemical substitution, and only in so far as uncombined bases are presented to them before consolidation of the silica, as quartz, do they lead to the formation of epigenetic silicates. Silica-bearing solutions capable of substitution carry the silica combined, usually with alkaline bases that are soluble in water at normal temperatures. These solutions must be sharply distinguished from the colloidal[1] silicious residuum of magmatic differentiation. The latter would exist as a fluid of relatively high density, in which a moderately high temperature is a pre-requisite to solvency. Such is not necessary in the case of alkaline vein-forming solutions of the sort that produce the great majority of the profitable gold mines of the world.

The connection between ore deposition and magmatic waters seems to be chiefly one of re-sorbed[2] roof-masses[3] carrying waters that were probably of meteoric origin. The distinction between strictly meteoric and strictly juvenile waters is a difficult one to draw. Much remains for the geologist of the future to demonstrate in this connection. It would appear necessary to show in any case of vein formation from ascending thermal solutions that these do not in reality represent the penetration of a massif[4] from above progressively with the cooling of the

[1]Colloid is a form of matter existing as a homogeneous suspension in a liquid, or as a continuous jelly, called a 'gel,' having pores filled with the liquid. They behave similarly to true solutes, unlike them they no not alter the freezing point nor the vapor tension of the solvent.

[2]'Re-sorbed' is a term indicating the fusion, into an intrusive mass, of fragments from the rock through which the magma, laccolith, dike, or other form of invading material, is being injected.

[3]'Roof-masses' are bodies of rock overlying an intrusive magma, laccolith, or other invading igneous body, and which frequently becomes detached, collapsing into the molten or plastic intrusive.

[4]'Massif,' in the older geology, has been applied to fault-blocks, that is, to a block displaced as a unit without undergoing any internal alteration because of such displacement. The term was restricted to blocks of great size, constituting important mountain masses, and usually of one species of rock with its normal differentiates. Since a magma represents a great petrographic unit considered as a portion of the deeper-seated crust of the earth under conditions resulting in fusion,

RHYOLITE INTRUDING SHALE.

ALASKITE INTRUDING SHALE.

magma after its consolidation, and also that the mineral load in solution is not merely the product of alteration of the rock under conditions of elevated temperature and pressure.

Differentiation of magmas does result in concentrations of certain metals, some preferring the attenuated silicious end and others the extreme basic pole of segregation.[5] This, however, is largely a matter of the normal chemical relations of the metals toward the bases and acids of the magma, rather than one of solvency in solutions. J. H. L. Vogt was one of the first exponents of the idea of metallic concentrations in magmas by differentiation, to which Mr. Spurr early gave his support. It is doubtful, however, whether concentrations formed in this manner are often of economic importance. There has been ordinarily a later concentration by circulating waters, or by diffusion through the capillary waters, to finish the work begun within the still plastic magma.

It is difficult for the miner to understand how relatively thin tongues or sheets of igneous rock can remain fluid long enough to permit of penetration for a great distance into presumably cold rock. In the first place, the intrusion took place usually at a depth where the temperature was higher than at the surface. Next, the outside of any intrusive mass cools so as to form a protection against the radiation of heat, the solidified exterior coat acting as an insulating cover. Finally, there is the fact of the feeble conductivity of most rocks of the earth's outer envelope. The slag in the pot of the smelter remains molten because the shell, or 'skull,' formed by cooling contact with the iron, prevents the escape of heat. At Bendigo, in Australia, dikes less than a foot thick can be seen making their way through three or four thousand feet of sandstone and slate, and the portion of their course that may be observed is only a fraction of that which they must have traversed. Even with an explanation it seems astonishing that a mere thread of lava (at Bendigo it is a basic phase of dolerite) should work its way amid fractures and faults through much older rocks for such a distance. There the sandstone and slate are of Lower Silurian age, while the dolerite is Miocene, so that a vast interval of time separates the periods of their origin. It must be observed that the lavas capable of intruding great distances in the form of thin sheets or 'sills' are of the more basic kinds, which require a large degree of superheat to cause fusion, but which remain pasty for longer periods than acid rocks at similar temperatures.

it becomes a petrographic unit, and is generally labeled a 'massif.' Thus the term becomes one suitable to distinguish between the petrographic unit after its consolidation and the same unit while still having motive power for intrusion, which latter condition involves mobility, whether due to actual fluidity or to mere plasticity. The magma is the mobile igneous rock; the massif is the consolidated igneous rock.

[5]'Segregation' is the tendency developed in rocks during their mobile period, and during their successive stages of consolidation, to separate, or split, into fractions, each fraction possessing a certain characteristic homogeneous chemical or mineralogical composition, different from other fractions produced within the same magma.

Alloys in Engineering Construction

*Among the more important materials of construction are alloys usually differing in properties from the metals from which they are made. The most extensively employed alloys are those of which copper is the base. In these copper is mixed with zinc to make brass or with tin to make bronze. Both brass and bronze have been used from remote antiquity. Brasses cover a range of from 55% copper and 45% zinc to pure copper. The alloys containing from 63 to 70% copper are known as 'high brass.' These especially combine strength, uniformity, toughness, and ability to withstand manipulation. They are not capable of being worked hot, but are used in sheets and strips, seamless tubes and wire. The value of these 'high brasses' is due to their resistance to corrosion, and ability to withstand forming operations.

Muntz metal contains between 55 and 63% of copper with 45 to 37% zinc; it is strong, relatively cheap, and can be worked hot. Seamless tubes of Muntz metal are made by the Mannesmann process, by which solid cylindrical billets are pierced by hot rolling and subsequently finished by cold drawing. Lead, up to 3 or 4% is added to Muntz metal, forming a mixture that can be easily machined at very high cutting-speeds and can, at the same time, be readily extruded. For purposes where great strength is essential, Muntz metal is alloyed with as much as 1½% tin, or tin and iron. The former mixture is the rolled bronze of the U. S. Navy, while the latter constitutes manganese-bronze.

Alloys containing about 80% of copper are called 'low brass'; with 90% of copper, 'commercial bronze'; while those with 95% of copper are termed 'gilding.' The bronzes are next in importance to the brasses; they consist of copper alloyed with tin. In the production of satisfactory bronzes it is necessary to use a flux; phosphorus is usually employed, forming phosphor-bronze. This material has an extensive application where hardness, strength, and reliability are required. Red brass is a term applied to alloys of copper, zinc, lead, and tin; a very wide range of strength, toughness, color, cost, and machining qualities may be obtained. The copper ranges from 76 to 87%, lead from 3 to 6%, tin from 2 to 7%, and zinc from 3 to 16%.

A standard mixture for bearings when heavy pressures are to be met is 80% copper, 10% tin, and 10% lead; phosphorus is used as the flux. Aluminum-bronze contains a maximum of 10% aluminum; the strength increases with the increase of aluminum, but the ductility decreases with the highest strength of 85,000 lb. per square inch. Nickel and copper readily alloy and yield products having useful qualities, but are expensive. Monel metal is a natural alloy in that the copper and nickel are mixed in the ore from which it is made; it contains 68% nickel, 2% iron, 30% copper, and has a tensile strength of 65,000 lb. per square inch.

*Abstract of a paper by W. Reuben Webster, read at the International Engineering Congress, San Francisco, September 22, 1915.

What Constitutes a Mining College?

By P. B. McDONALD

The number of mining colleges and schools of mines that are springing up over night suggests naturally that not all of them are necessary. Obviously the quantity as well as the quality of mining engineers that can be absorbed advantageously into the mining business has limits. Equally obvious is the fact that incapable colleges, with a backing of bumptious superficiality, will detract both in students and standing from institutions of worth. The point then is: What is a real mining college and what is merely an imitation? What is the prime requisite? A building? Advertising? An appropriation? Location? Equipment? Professors? How is the prospective student to choose a college? In which institution will he really learn mining and metallurgy and absorb the spirit to succeed in the profession; and in which will he find mining merely a farce, where dilletanti "take geology with the girls" or otherwise fail to appreciate the point of view that makes for success in a particularly arduous career.

The essentials for a real mining college can be divided under two heads: the first class includes such practical matters as location and equipment; the second pertains to the less material but equally important consideration of the men behind the institution, graduates, professors, and instructors, trustees or Board of Control, and the students themselves.

A school of mines must have either a location in a broad-gauged mining district where operating mines can be visited and inspected, or it must have a large and costly equipment to show, in miniature, what mines, mills, and smelters are in reality. A college having neither adjacent mines nor adequate equipment is in no position to inculcate a knowledge and understanding of mining in young men, many of whom never saw a mine and most of whom have extremely hazy ideas as to what underground operations look like. The variegated and elaborate equipment for a proper teaching of mining and metallurgical operations can scarcely be accumulated in a hurry. Time and experience are required to develop the combination best suited to fulfill the requirements. There is a great deal to be said for a mining college that teaches nothing but mining. Where all efforts and endeavors are bent toward producing a single effect, the result is especially helpful to a subject so difficult to teach as mining.

But by far the most important side of a school of mines is the men who make it. It is well, in judging a college, to look at the men it has produced. There is a certain indefinable quality or stamp placed on the men that have graduated from particular institutions. The idea behind this factor is indicated by the recent remark of a president of a well-known mining college. It was as follows: "The minute a professor begins to think more of his remuneration than of ideals of teaching, he is no longer fit for his position. It makes no difference how much he knows, he has lost his usefulness." A college with ideals contributed by the men who have been associated with it is a real college. A building, no matter how ornate, an appropriation no matter how magnificent, and a professor of mining without ideals serve to furnish only an imitation of a thing that does not stand imitating at all well. A man without principles is not worth a damn; neither is a mining college. Both can make a splurge for awhile, and can muster up a make-believe that may look like the real thing. But both are equally useless in the end, and are likely to do more harm than good.

A popular university, a year or two ago, decided to install a course in mining. For the head of the new department, the institution offered to an unusually capable assistant-professor of mining, in a mining college of high standard, a substantially better salary than he was then receiving. To the astonishment of the university officials, the assistant-professor in the small college declined with thanks the opportunity to become head of the new department of mining in the large university. This is not an isolated instance; other cases of the same kind are on record. To the average outsider, a man who refuses to better his position and salary—particularly his salary—seems so unusual in these modern days as to be more or less of an oddity, and to betray poor judgment. But it is to be remembered that seeming to be doing something is not always more productive than actually doing something, especially when a long period of time is considered.

A student picking out a mining college to attend might do well to keep in mind that the one which makes the most noise is not necessarily the best for him. Nor need the one that is nearest be the surest to put him farthest in the long run. It is not where he is at 25 years of age that counts; it is where he will be later on. The influence of a good training will extend over the whole life of its graduates.

GOLD in sea-water was the basis of a swindling company, at North Lubec, in Maine, that collapsed in 1898. Gold exists in the ocean at the rate of about two cents per ton of water; in San Francisco bay the quantity is equal to four cents per ton, and in Salt Lake rather more than in the ocean. The most attractive method of extracting this gold would seem to be the treatment of the bittern or residual water from the manufacture of common salt; this is a solution concentrated in the proportion of 100:1 so that one ton of bittern ought to contain about $2 in gold. Hence, this brine contains more gold than the ore of the Wasp No. 2 or the Alaska Treadwell. Who will be the first to treat it commercially? Another Rev. Jernegan?

GOLD OUTPUT of the Transvaal for the first half of 1915 totaled 4,408,048 oz. At the current rate of production the year will yield about $10,000,000 more than in 1914.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Condensed sea-water is the only available supply for the power-plant of the Chile Copper Co. at Tocopilla. Oil-fired water-tube boilers are used.

In acetylene lamps for mines, one ounce of good carbide makes about 500 cu. in. of acetylene gas. An ordinary miners' carbide lamp uses nearly half an ounce of carbide per hour, making up to 0.144 cu. ft. of gas.

Decomposition of sulphide ore, forming acid, which came into contact with limestone of the Albion mine, Little Cottonwood district, Utah, is considered to be the cause of accumulation of gas that resulted in an accident lately.

Zinc oxide is always present in zinc-dust, varying from under 5 to over 20%. Dust containing over 15% oxide should not be used for precipitation in cyanide-plants. Zinc-dust does not oxidize much in dry air, but in a moist atmosphere oxidation is rapid to a certain point, when the rate decreases.

Scheelite, a tungstate of lime, is used for hardening steel. It is generally mined alone, but the number of instances where it occurs with gold is increasing. Among these are a deposit in the South Island of New Zealand, the Wasp No. 2 mine of South Dakota, the Suan Concession in Korea, the Atolia district in Kern county, California, and in the Union Hill mine at Grass Valley.

Advantage of the replacer over the thickener-dilution method at the West End mill, Tonopah, is considered to be in the smaller installation required, and the amount of barren solution required compared with the large tonnage of barren and partly barren solution of the dilution method. The main drawback to the replacer system has been a lack of faith in its principles and mechanical features.

Coins are usually considered as made of gold, silver, nickel, copper, or bronze. Platinum was used formerly in Russia. An unusual coin is found in the Yap or Caroline islands, where limestone blocks are used as a measure of value. The small stones are in vogue for private trade, while for payment of war-indemnity stones up to two tons in weight are employed. One recently acquired by a Japanese museum is valued at $100.

Gold dredging, in its modern form, originated in New Zealand. In 1902 the maximum number of 202 dredges was reached. Since then the number declined until in 1913 there were but 74 dredges operating. The greatest weekly output by a New Zealand dredge was attained by the *Lady Ranfurly* during the six days ending November 4, 1904, when 1273 oz. of gold was obtained. This dredge, up to the end of 1913, had produced $1,077,000, of which $630,000 had been distributed in dividends.

In the Appleton, Wisconsin, filtration-plant, the water is treated with alum solution, passed through coagulating basins for settlement, and then pumped to the city mains after 2 lb. (10c. per lb.) of liquid chlorine per 10,000,000 gal. is added. Filtration reduces the bacteria present in the original river water by 98.5%, the chlorine destroying most of the remainder. The total cost is $6.18 per 1,000,000 gallons. This offers a good suggestion to managers of mines, desirous of promoting the health of the community.

The chief market for cobalt oxide, the ceramic works of Europe, has been closed by the War. Consequently the shipments from the silver refineries of Cobalt, Ontario, have been greatly reduced, falling off in value 85%, from $379,152 to $56,812. Some consignments have been made to Great Britain and the United States. Metallic cobalt is now being produced both at Deloro and Thorold, Ontario, and is finding a use in the manufacture of high-grade and high-speed tools, also for the plating of metallic objects, replacing nickel for this purpose.

Silver in the Tonopah-Belmont mine occurs as silver sulphide, antimonial silver sulphide, arsenical silver sulphide, with iodine as a base, and native silver; probably deposited somewhat in the following order:

Silver sulphide	argentite
Antimonial silver sulphide	stephanite, pyrargyrite
Arsenical silver sulphide	polybasite, proustite

Silver iodide, chloride, bromide, and native silver. The ore contains 72% silica.

Acetylene lamps have been used exclusively in the Granby Consolidated company's copper mines at Phoenix, British Columbia, since the end of 1913. The carbide light is considered much superior to candles, particularly where large openings result in a good draft. The candle bill was 0.0053c. per ton of ore; the carbide cost 0.0039c., over two periods of 14 months each. Miners pay for their own lamps, the company supplies carbide and repairs, but the men take care of them. In the Le Roi No. 2 mine, at Rossland, the carbide light is said to affect the men's eyes.

Over-thrusts or fold-faults are especially connected with anticlines and occur as the end result of an intense plication. There is often no sharp boundary between the disturbed zone along which the thrust has taken place and the undisturbed beds; but generally there is a gradual passage from crushed material to normal deposition. The extent to which beds are displaced by over-thrusts varies from a few inches to hundreds of yards or even miles. Swiss geologists, especially Maurice Lugeon, consider that over-thrust folds, where the displacement amounts to a hundred miles, or more, account for much of the structure of the High Alps.

Eastern Metal Market

New York, October 1.

With the exception of tin, all the metals have a reasonably strong tone, and prices have been advanced, or at least maintained. Copper, under the influence of some large buying on both foreign and domestic account, has advanced, and electrolytic is quoted at 18 to 18.25c., New York. It is hoped that the clearing up of the foreign loan will bring England into the market. Zinc rose to 14.50c., New York, under a good demand for spot and nearby deliveries, but is now showing a somewhat easier tendency. Lead is very strong, with independents asking a shade over the quotation of the A. S. & R. Co., while second-hands are unwilling to sell unless at an attractive figure. They are more disposed to buy. Tin has been dull, and at the end of the month was most adversely affected by the fact that there was in stock and landing no less than 4546 tons. Antimony has slightly greater strength because of an impending Government purchase; but consumers in general are showing little interest. Aluminum continues scarce for delivery inside of the next few months, and some lines are severely affected by the high prices.

In the steel trade the great question continues to be one of deliveries. Foreign consumers and makers of steel rounds for shells continue to take enormous quantities of unfinished steel. The general quotation for plates, shapes, and bars is now 1.40c., Pittsburg, with some of the mills asking 1.45c. The railroads are buying more cars, locomotives, and rails, though of the last named it would be impossible to get large deliveries in the near future. Sellers of foundry pig-iron are holding firmly to their advanced prices for 1916 delivery, although melters are slow in getting on the order books.

COPPER

In the past few days there has been some heavy buying of copper, especially for export to France, although a few domestic consumers having large war contracts have also been purchasers. Several million pounds has been taken. Now that the details of the $500,000,000 Anglo-French war loan are completed, it is hoped that England will soon come into the market for a large quantity. The New York quotation for electrolytic went to 18c. cash on September 27, following the taking of some large quantities. Wall Street appears to be playing a larger part than usual in the matter of prices, many of the trade declaring, more or less facetiously, that copper prices are today made in that district. Of course it is to be considered that financial conditions do have a large effect on business generally. Some of the producers are now asking 18.25c., 30 days, delivered, and a few quote 18.50c., but business has been done at 18c., in fact, that is the price said to have been paid in recent large sales. Lake is quoted at practically the same price as electrolytic, 18c. cash. One phase of the market which is a bull influence, is that second-hands have practically withdrawn offerings, and this they seldom do unless they anticipate higher prices. It remains a fact that purely domestic, industrial consumption, such as is so largely depended on in times of peace, has not improved to any great extent. The exports this month make another poor showing, totaling 14,327 tons.

ZINC

From 13.75c., New York, quoted on September 22, the spelter market has advanced to 14.50c. for spot and nearby metal. A good business was done up to the first of this week which carried prices upward. Since then a slightly easier feeling has been manifest. Futures continue to excite but slight interest. The London market advanced £2 per ton on September 30, but the price there was still over ¼c. below New York parity. Quotations for delivery to the end of the year range down to 13.25c. From Baltimore comes news of the arrival there of the first cargo (4500 tons) of Australian zinc concentrates consigned to the United States Steel Corporation for its new smelter at Donora, Pennsylvania. Exports last month aggregate the excellent total of 4914 tons.

Sheet zinc is unchanged at 16c. base, f.o.b. mill, carload lots, 8% discount for cash.

LEAD

The lead market has been steadily gathering strength, and day after day it has been expected that the A. S. & R. Co. would announce an advance in its price which for some time has stood at 4.50c., New York. Outsiders have not only been unwilling to sell at 4.50., but second-hands have been buying lead at 50c. per ton advance over the Trust price. A fair business is reported. London has been getting stronger also, the quotation there advancing on September 30 2s.6d. to £23 17s.6d. Exports from September 1 to 30 totaled 2628 tons.

TIN

Just prior to September 30 the market was showing a better tendency, but the appearance of the statistics showing that deliveries for the month had been only 4300 tons, whereas there was in stock and landing at the end of the month 4546 tons, caused quotations to soften. On September 28 the market rose to 33.25c., but two days later it was down to 32.50c., and on Friday the quotation was 32.25c. For many days the market has been exceedingly dull, with no interest shown in any positions, and spot and futures quoted alike. Arrivals of tin at and for Pacific ports in September aggregated 347 tons, making the total for nine months 1230 tons, approximately the same as in the same period of 1914. The following classification of tin imports since January 1, was compiled by the secretary of the New York Metal Exchange, C. Mayer.

	1915.	1914.
Straits	*31,466	28,429
Australian	10	45
Banka and Billiton	2,936	246
English	2,215	2,610
Chinese	1,130	895
Sundries	178	679
Total tons	37,935	32,904

*11 tons exported deducted.

ANTIMONY

A temporary factor lending a better tone to the antimony market is a request for bids on 50 tons for delivery to the Frankford arsenal, Philadelphia. The quotations still range, however, from 28.25 to 28.50c. for Chinese and Japanese grades. Domestic antimony is offered at ½c. less than the minimum for imported.

ALUMINUM

The quest for aluminum for prompt delivery continues, and the scarcity is such that 48 to 50c. is asked. As matters now stand only an increase in the production can bring about easier prices. Probably this would have eventuated before this had not the War tied up foreign capital interested in aluminum projects in this country. The high prices have created a severe situation for the makers of die castings, who use considerable quantities of aluminum in the alloys which they cast into parts for the automobile makers. The die-casting trade has had a struggle for existence. In the future more attention will be paid to the reclamation of aluminum scrap on which subject the U. S. Bureau of Mines will soon issue a paper describing commercially successful processes. Melters of scrap have met with many difficulties, owing to trouble in securing a proper coalition of the metal when chips coated with oxide, oil, and dirt are melted.

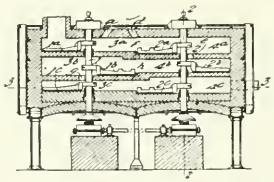
Recent Patents

Process of Precipitating Copper from Solution. George D. Van Arsdale, East Orange, New Jersey. Filed December 26, 1907. Serial No. 408,127.

1. The herein described process of precipitating copper from a solution of a copper salt which consists in precipitating copper from the solution by adding sulphur dioxide thereto, and in neutralizing free acid formed by the re-action, during the time of the precipitation.

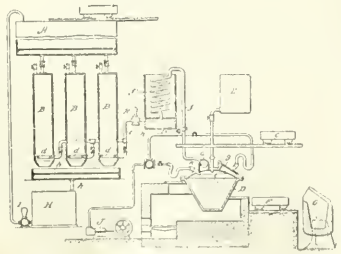
2. The herein described process of precipitating copper from a solution of copper sulphate which consists in precipitating copper from the solution by adding sulphur dioxide thereto, and in neutralizing free acid formed by the re-action, during the time of the precipitation.

Ore Roasting or Drying Furnace. Harry Mackenzie Ridge, London, England. Filed October 6, 1913. Serial No. 793,666.



1. In multiple hearth furnaces for roasting or drying crushed ores or the like, having two or more vertical shafts carrying arms which rabble the ore and cause it to traverse successive hearths in opposite directions, means whereby superimposed portions of said successive hearths and the relative rabble shaft or shafts and rabble arms can be put out of action without interfering with the working of the other part.

Recovery of Cuprous Sulphide from Ores and the Like. Raymond F. Bacon, Pittsburg, Pennsylvania, assignor to Metals Research Company, New York, N. Y., a corporation of Maine. Filed January 24, 1914. Serial No. 814,147.



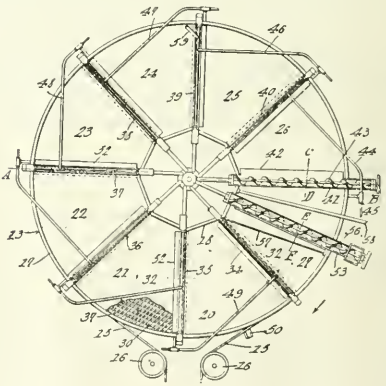
1. The method of recovering cuprous sulphide from ores and the like, which consists in leaching out the copper therefrom by a suitable solvent, precipitating the copper from the solution as cupric sulphide by means of hydrogen sulphide, thus regenerating the solvent, reducing the cupric sulphide to cuprous sulphide by means of a hydrocarbon with the simultaneous production of hydrogen sulphide, and using the hydrogen sulphide thus produced for the precipitation of cupric sulphide from a further quantity of the copper solution; substantially as described.

Ore Concentration. John W. Littleford, San Francisco, California, assignor to Minerals Separation, Limited, London, England. Filed December 15, 1913. Serial No. 806,770.

1. The hereindescribed process for separating the valuable metalliferous constituents from the gangue slimes contained in ore pulp which consists in coagulating the said gangue slimes by adding to the ore pulp an emulsion of a soap and pine oil, and separating the coagulated gangue from the metalliferous constituents of the pulp.

2. The hereindescribed process for separating the valuable metalliferous constituents from the gangue slimes contained in ore pulp which consists in adding to the ore pulp an emulsion of soap and pine oil in approximately the proportions by weight of 32 parts pine oil, 9 parts anhydrous soap, and 59 parts water, and thereafter separating the coagulated gangue from the metalliferous constituents of the ore pulp.

Ore-Leaching Apparatus. Murray C. Godbe, Salt Lake City, Utah. Filed December 3, 1914. Serial No. 875,354.

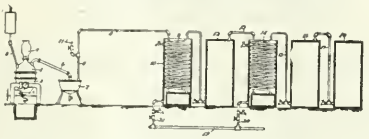


1. Apparatus of the class described, including a horizontal table mounted for continuous rotation, said table including separate non-communicating compartments and a continuous filtering medium extending over the compartments, means for feeding a layer of material onto the filtering medium, means for subjecting the moving layer of material successively to the action of a countercurrent of leaching solution, said solution gradually diminishing in strength toward the point where said material is fed onto the table, and means adjacent the feeding means for removing material from the filtering medium subsequent to the action thereon by the strongest portion of the solution.

Method of Treating Metalliferous Materials and Recovering Solvents Used. Harry D. Rankin, Crafton, Pennsylvania, assignor, by mesne assignments, to Rankin Process Company, Phoenix, Arizona, a corporation of Arizona. Filed July 17, 1909. Serial No. 508,108.

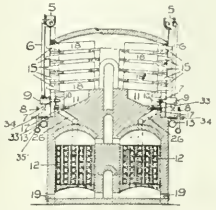
1. The method of treating metalliferous material containing acid forming substances for the purpose of recovering the values contained therein, which consists in treating the same in a closed vessel with nitric acid while subjected to pressure and maintaining it at a temperature below 125°C.

2. The herein described method of treating ores and metalliferous bodies, which consists in treating finely divided metalliferous substances with carbonic acid gas at suitable tempera-



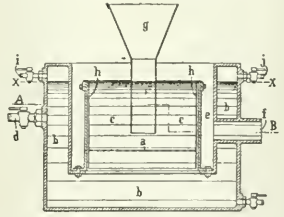
ture and pressure, to form soluble bicarbonates, and removing the same from the residue, and then treating the residue with nitric acid, and recovering the NO evolved to form HNO_3.

Method of Smelting Sulphide Ores. Henry L. Doherty, New York, N. Y. Filed April 20, 1911, serial No. 622,360. Renewed January 19, 1915, serial No. 3154.



1. The process of treating zinc sulphide which comprises pulverizing the sulphide, burning the pulverized sulphide in aerial suspension to heat a spelter furnace for the reduction of oxidized zinc, separating the zinc oxide formed by the said combustion from the gaseous products of the combustion, mixing the said oxide with the proper proportion of carbonaceous material and smelting the said mixture by the heat generated by the combustion of fresh sulphide.

Apparatus for Separating Minerals and Like Materials. Friederich Arthur Maximilian Schiechel, Frankfort-on-the-Main, Germany. Filed August 22, 1910. Serial No. 578,440.

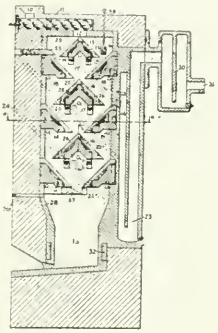


1. In apparatus for separating minerals and like materials, a separating compartment having a bottom formed by a perforated or foraminous bed, a surrounding annular compartment communicating with said separating compartment, from underneath the perforated or foraminous bed, a water supply pipe furnishing said communicating compartment with an uninterrupted water stream continuously rising in the separating compartment, a closed air chamber above the water line of the communicating compartment, means for applying intermittent air pressure within said air chamber, a discharge compartment into which discharge the water and tailings overflowing the upper edges of the separating compartment, and means for feeding material to the separating compartment.

Electric Reduction of Zinc Ores. Woolsey McA. Johnson, Hartford, Connecticut, assignor to the Continuous Zinc Furnace Company, Hartford, Connecticut, a corporation of Connecticut. Filed October 17, 1912. Serial No. 726,254.

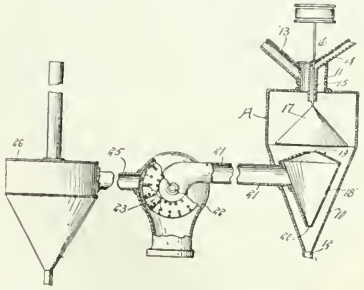
1. In the electric reduction of complex zinc ores, including in their analysis sulphur, lead, and calcium or barium, preliminary calcining said ores to the substantial elimination of sulphates with the exception of sulphate of lead and such sulphates of calcium, and barium as are present, and then reducing the residual sulphates to sulphides; substantially as described.

Electrical Furnace. William H. Hampton, New York, N. Y., assignor to the Conley Electric Furnace Company, Incorporated, Wilmington, Delaware, a corporation of Delaware. Filed February 28, 1913. Serial No. 751,258.



1. An electrical furnace for the reduction of zinc or the like provided interiorly with a staggered arrangement of guide members extending in proximity to each other and partly inclosing a plurality of connecting cavities with sloping surfaces over which the material flows from one to another in a zigzag downward course, non-arcing resistance means in the interior of said guide member for internally heating the surfaces thereof so as to heat the material as it flows thereover, and means for leading off at different levels from said cavities the material vaporized from the charge.

Ore-Separator. Charles H. Brown and Charles C. Parker, Eureka, Utah. Filed April 20, 1915. Serial No. 22,634.



A device of the class described comprising a casing having an air inlet and a material inlet in its upper end and a material outlet in its lower end, a rotatable spreader within the casing beneath the material inlet, a second casing disposed within the first casing beneath the spreader and having openings in its upper and lower ends respectively, said lower end being in proximity to the lower end portion of the outer casing, and a suction device connected with the interior of the second casing.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

Gold Output.—Drainage-Tunnel.—Electric Signals.—Water Pipes Over Bad Ground.—Strong and Queen Development.—New Plant to Treat Surface Material.—Dump Treatment.—Modoc Mine.—Placer Operations.—Jerry Johnson Mill.

The output of the district for September, as reported by the mills and smelters, is as follows:

Plants.	Tons.	Average value.	Gross value.
Golden Cycle, Colorado Springs	43,000	$18.00	$774,000
Portland, Colorado Springs	10,300	21.00	216,300
Portland, Battle Mountain, Cripple Creek	19,150	2.88	55,150
Portland, Independence, Cripple Creek	9,900	2.00	19,800
Gaylord-Dante	1,500	3.50	5,250
Caley	1,117	3.46	3,864
Kavanaugh-Jo Dandy	1,000	2.00	2,000
Smelters, Denver and Pueblo	3,875	55.00	213,125
Total	89,842	$14.35	$1,289,489

In the Roosevelt drainage-tunnel a new water-course has been cut, resulting in an increased flow of 1500 gal.; the total quantity is now over 12,000 gal. per minute. During August the advance in the breast was made at an average rate of 7½ ft. per day.

The Empire State shaft of the Isabella property is temporarily closed. A new system of electric-light signals will be installed. It will be a good one, being selected by the mining inspector. A few days ago a confusion of hoisting signals resulted in the accidental death of two men who were caught in the shaft timbers; hence the new apparatus.

The city of Victor and the Portland Gold Mining Co. have entered into an agreement whereby all trouble relative to the danger of breakage in the water-pipe has been eliminated. The main, which supplies Victor with water, crosses old filled and open stopes, and gradually settling ground between the Independence and Portland mines. It has long been a source of danger and menace to the Portland, Strong, and Independence mines. By the terms of the new agreement the pipe is to be taken up and re-laid where it will be safe. The Portland company will bear part of the expense of moving the main.

It is reported that the Strong Gold Mining Co. has opened a good shoot of ore by driving south from the new bottom level, about 1350 ft. below the surface.

At the Queen property in Eclipse gulch, a large quantity of medium-grade ore is being mined and sent to the Golden Cycle mill at Colorado Springs. This property was purchased by the Golden Cycle Mining & Milling Co. about a year ago. It has been idle since then until a few weeks ago.

A new concentrating plant has recently been installed at the Kitty Hollis property near the north end of the district. The whole hillside is being scraped, the material passed over screens and then washed. Quicksilver is used to save the fine free gold. From 50 to 75 tons is being treated each day.

As a result of the dry and clear weather of the past month, many of the old dumps are being worked; considerable revenue is obtained from this source. A dump-treatment plant is being constructed on the Elkton waste heaps. It will treat about 200 tons of ore per day. A steam hoist of the double-drum type, mounted on top of a 30-ft. ore-bin, operates a drag-bucket and lifts the ore to the top of the bin. Here the ore is passed through three different processes of sorting and screening.

At the Modoc property, between Battle mountain and Bull hill, sinking is in progress below No. 15 level. An ore-shoot over 200 ft. long has been opened on the level above. Development will soon be started to prove the persistency of this ore on the new lower level.

Old friends of the district will be interested in a small revival of placer mining in Poverty gulch on Cripple creek. Sluice-boxes, flumes, and the ordinary gold-pan are employed. Occasional small nuggets are found. Much of the gold is combined with iron sulphide and is not saved. Good wages are being made from the gold that is free.

The recently erected Jerry Johnson mill has proved successful in its trial run and clean-up. This plant embodies the cyanide process. In addition to dump ore, low-grade mine, and even smelting-grade ore will be treated.

DEADWOOD, SOUTH DAKOTA

Mining and Treating Gold-Antimony Ore.—Two Johns Mine.—Tailing Trouble.—Mogul Mill.—Golden Reward Roasting Plant.—Echo, North Homestake, and Hidden Treasure.

Gold-antimony ores of the Silver City district, Pennington county, are being exploited by the Home Lode Mining & Milling Co. The ores, containing gold, silver, antimony, lead, and zinc, occur in quartz veins a foot or so in width, between walls of Algonkian schist. Two of these veins are being developed on Home Lode territory; several others crop on the surface, but have not yet been opened. One of the veins has been opened by an adit 200 ft. long connecting with a shaft at the 100-ft. level. This shaft practically follows the ore from the surface to the adit level, while a winze 50 ft. deep shows the shoot to be continuous to that point. In these workings the deposit is from 12 to 18 in. wide, and about 150 ft. long. The value is mainly in gold and antimony, although assays show the presence of some silver and lead. The second vein is about ¼-mile east, and its north-south course parallels that of the first vein. Two shafts, 370 ft. apart, one 66 ft. and the other 103 ft. in depth, demonstrate the continuity of the vein for that distance. This ore-shoot is approximately 24 in. wide, and contains an appreciably greater amount of the zinc mineral, sphalerite, as well as more pyrite, than the No. 1 shoot. Treatment of the ore consists of amalgamation and concentration. Using a 7-ft. Lane slow-speed mill, with a high discharge, making a product which will all pass through a 60-mesh screen, amalgamation is done in the mill by using an excess of quicksilver. Outside amalgamation, with copper plates, has not been successful, but tests with silvered copper plates indicate that better results can be got with them. As soon as the plating can be done by the Homestake company, a thorough test will be made with the plates. A Deister double-deck slime-table has given satisfaction, making three products, namely, an antimony-lead finished concentrate, an iron-zinc middling, and tailing. Another table will be installed to re-concentrate the middling and make a zinc product that can be marketed. L. A. Richards is general manager, and L. L. Farnam superintendent.

The Two Johns mine on Squaw creek, north of Trojan, has

been leased to B. D. Hynes. He will ship ore to the Mogul mill. This property has been a producer for years, although never equipped with a mill. The dump contains a considerable amount of ore that will be profitable on cyaniding, while many of the old stopes expose remnants of shoots that should yield a profit. In former years the product was mostly of smelting grades, and in mining it considerable milling ore was untouched. For the present, Mr. Hynes will have the ore hauled by team to Crown Hill station on the C. B. & Q., a distance of a little over a mile, but should development warrant, he proposes installing an aerial tramway.

Having been forced to suspend milling ou account of the tailing polluting the waters of Bare Butte creek, the Rattlesnake Jack plant, at Galena, will be equipped with an Oliver filter, an order for the machine having been placed. The tailing from the filter will be stacked and thus be kept out of the creek.

With the newly installed De La Vergne oil-engine in use, the Mogul mill, at Terry, is treating nearly 200 tons per day; previous to this additional power installation, the capacity of the plant was only a little over half of that quantity. Further improvements to the plant, which are contemplated for the near future, include the addition of a suitable filter for dewatering the tailing. At present the mill is using a straight agitation and counter-current decantation system, the product of the final thickener going to the dump. It is proposed to filter this product. The plant is one of the most popular in the Hills for treatment of custom ores, probably due to the fact that the treatment charge has been fixed at $1.50 per ton for low-grade material.

Fifty to sixty tons daily is being treated at the Golden Reward roasting plant, at Aztec, preliminary to its cyanidation at the company's mill at Deadwood. The so-called 'bard blue' ores of the Billy and other neighboring mines, containing 3 to 4% sulphur, are given a roast at 1200°. This temperature, while it does not give a sweet roast, eliminates enough of the sulphur to make a product which yields 90% extraction in the cyanide-plant. Without roasting, these ores seldom give better than 35% by cyanidation. The ore is received in bottom-dump railway-cars which discharge to ore-bins above the crusher. From the crusher the product is elevated to a bin feeding to a Ruggles-Cole dryer. Thence it passes to two sets of rolls which reduce it to 6-mesh. It is then fed by belt-conveyor to a Wedge furnace using, as does the dryer, Wyoming crude oil as fuel. After roasting, the ore passes through coolers and is elevated to a cylindrical steel bin, from which it is drawn to railway cars for shipment to the mill at Deadwood, where it is further ground in a pebble tube-mill and cyanided. The furnace is driven by a 10-hp. motor using a litttle over 4 kw., although about twice that amount of energy is necessary to start it. Oil consumption is 13 to 14 gal. per ton of ore roasted; this oil costs, delivered, a trifle over 3c. per gal. The total costs at this plant, including crushing, drying, and roasting, are under $1 per ton of ore handled.

To provide steam for operation of the sinking pump, a small boiler has been installed by the Echo company, at Maitland. The shaft, now 175 ft. deep, will be continued to 200 ft., where an electric station pump will be used.

Two shifts of miners are employed at the North Homestake mine, at Maitland, developing a promising looking vein on the 600-ft. level.

About 60 ft. of cross-cutting has been done east and west from the bottom of the Hidden Treasure shaft. Some fair gold ore has been found, as well as a small quantity of native copper.

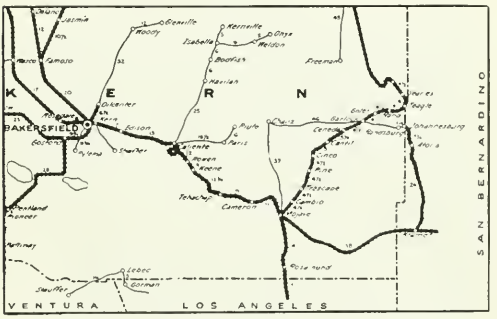
According to Charles W. Henderson, of the U. S. Geological Survey, the gold and silver output of South Dakota in 1914 was 351,865 and 172,574 oz., respectively, from 2,019,262 tons of ore. Practically all of this was from Lawrence county. Amalgamation recovered 218,644 oz. gold and 63,734 oz. silver, and cyanidation 133,221 oz. gold and 108,840 oz. silver.

ATOLIA, CALIFORNIA

TUNGSTEN MINING IN SAN BERNARDINO COUNTY: MODE OF OCCURRENCE, LEASING, STAKING, TREATMENT.

The new equipment being installed by the Atolia Mining Co. will begin operation about October 15. It includes a Marcy mill with a capacity of 100 tons per day, seven Frue vanners, and eight double-deck sand and slime concentrators, besides filtering apparatus. There are about 200 men, including lessees, now engaged in producing scheelite ore, which is all shipped to Eastern markets.

There have been several new discoveries of scheelite veins during the past year, none of which have been made on claims not owned by the Atolia company. Several miners who were leasing from this company under working contracts, by which all ore extracted reverted to the claim-owners at $3.50 to $4 per unit, have recently leased ground belonging to P. J. Osdick, and are making regular shipments of high-grade tungsten ore. Recent quotations from Eastern firms have advanced to $25 per unit, within two weeks, of 60% ore of WO_3, and even higher for better grades. An increased production has marked the recent rise in prices, and this dull little desert camp is gradually taking on the former activity of early days at Randsburg.



MAP SHOWING SITUATION OF ATOLIA AND RANDSBURG.

The desire to acquire tungsten producing mines has become keen, and the whole granite belt from the 'stringer district' near Randsburg, to Cuddaback lake is being staked by locators who load stakes into autos and cover a mile or two in a single day. The scene reminds one of the gold rush of 1896 when the St. Elmo mine (about two miles west of Atolia) was found, and locators double-staked the country on horseback. Not a little argument is shown over mining claims, though no bloodshed has resulted so far.

Tungsten is also being found near Randsburg on the Baltic, G. B., and Sunshine claims, which have for 19 years been known as gold producers. The scheelite found adjacent to these claims is in form of placer deposits, and the concentrates are usually better than 65%, which sell readily at the Randsburg stores for $1 per pound.

No more leasing contracts will be entered into by the Atolia Mining Co., and notice to this effect has been posted by the superintendent, Mr. Taylor, at the local stores and post-office. The completion of the new mill and stoppage of leasing, is the natural evolution of discoveries and development of the company's large holdings by lessees, and the output will be hereafter augmented by employees only at $3.50 and $4 per day.

Scheelite in this district occurs both in placer and fissure vein formations, which appear to be continuous, and run in an east and west direction. The richest ore is found along the spurs of nearly all veins as 'kidneys,' which vary in grade and size. Several have been found that are two to three feet wide

at depths from surface to 50 or 60 ft. As depth is attained, much of the vein matter shows alteration, and is termed 'dry bone' because of its poor quality. There are, however, several instances of over 70% ore being extracted at a depth of nearly 1000 ft. All promising veins without exception are found encased in lime at the surface, and no attention is paid to veins that are without the lime occurrence, because of this uniform peculiarity.

The production this year will be nearly 2000 tons, nearly all of which is shipped to the Pittsburg and Midvale (Pennsylvania) crucible steel companies.

Apropos of the increased capacity of the Atolia company's new mill, thousands of tons of tailing will be treated, and will keep the mill busy day and night for many months, and indirectly give employment to perhaps over 100 miners and others.

JOPLIN, MISSOURI

Floods Reduce Weekly Zinc Ore Production More Than 1000 Tons.—New Mill Building in the Oklahoma Fields.—General Activity in Zinc and Lead Districts.

Production of zinc-blende concentrate throughout the Missouri-Kansas-Oklahoma district is about 5000 tons per week at the beginning of October, compared with 6000 tons in the middle of September, the decrease being due to floods that have been general in all mining areas. In six hours' time, a rainfall of seven inches was recorded by the local weather bureau; at another time nine inches fell in the Spring City district, six miles south of Joplin, every mine in that field being filled to the surface. Great damage has been done to mining properties along Spring river, Center creek, Turkey creek, and Shoal creek, all of which streams flow through the district from east to west. Along Center creek in particular are situated many of the district's largest mines and many of these have been placed out of commission for some time. Surface waters flooded many mines that were not adjacent to any stream, and small mines have been especially heavy sufferers. Drill prospecting has been suspended temporarily, as it is impossible to carry on operations with the ground so thoroughly saturated with water. Curtailment of production has caused a brisk demand for all grades of ores; and the second-grade products that have not been in nearly as strong demand as the choicer lots for the past few months, are now commanding almost as high a basis settlement as the best grades. The range in price at the beginning of October was $70 to $80, basis of 60% metallic zinc. Calamine was in good demand at $50 to $60, basis of 40% metallic zinc, with production at low ebb, as the calamine producers felt the effects of the floods severely. Lead found a ready market at $50 per ton, basis of 80% metal.

Operations have started at the new mill of the Century Lead & Zinc Co., on an Indian lease in north-eastern Oklahoma. Two shoots of ore are mined, the lower, occurring at a depth of 190 ft., being the more extensive than the upper. A small concentrating plant of 150-ton capacity is all that is required to handle successfully the grade of ore found at this place, and this is the size of the new Century mill. The completion of this mill follows closely on the finish of the Vantage plant in the North Miami district. Steady 'turn-ins' of zinc and lead concentrates are now being made by the Vantage company. North of the Miami camp two plants are to be started soon by the Commerce Royalty Co., which already is operating several mills in the Miami field. One of the new ones, each of which will have a capacity of 200 tons, will be situated on the Blue Goose land, not far from the Century mill, while the other will be on the Beaver tract. Still farther to the north, and just south of the Kansas State line, the new work being done by the Picher Lead Co. is of much importance. Three of the eight shafts being sunk are now in ore, and work is being rushed on the remaining five. Mill construction is soon to be commenced on a big scale.

A mining area that showed some activity for several years, and which lapsed into a state of general inactivity for a number of years, until the recent increase in zinc-ore prices caused a renewal of mining operations in all districts, is the district six miles south-east of Joplin, and almost due south of the little camp of Duenweg, Missouri. On various tracts in that district new propecting work has been started, and in some instances old mines have been taken over and are now being worked. Calamine production is fairly heavy in that region at the present time, as the result of operations in shallow deposits. M. Sweetman, of Kansas City, has three good drill strikes of lead and blende at a depth of 140 ft. on the T. C. Molloy lease. The drills continued in ore to a depth of 195 ft. Molloy and associates have a new shaft in ore south-east of the drill-holes mentioned. The Mary E mine on the same land is being placed in operation. Adjoining the Molloy lease on the south is the Greenhorn tract, on which Bell & Co. are operating a recently-constructed mill, and are producing both blende and lead. South of the Greenhorn is the Knight 40-acre tract, on which some recent drilling has shown ore at various levels. On the Weymann land, still farther south, shallow calamine development is being carried on.

Along with new mill construction, the building of tailing-mills and sludge-mills is of much importance. The high price of zinc ore has made it possible to handle old tailing and sludge-ponds profitably. A new tailing-mill has just been constructed by the Martin Tailing Mill Co., on a lease of the Wysbrod land, four miles north-west of Joplin. A new sludge department is being added by E. D. Hornbrook to the Providence No. 2 mill, on the Missouri Zinc Fields Co.'s lease, south of Webb City. This plant is one of the largest in the district, having a capacity of 500 tons, and with the new sludge department added the capacity will be increased. Mining will be conducted at a depth of 190 ft. in sheet-ground.

LONDON

Cornwall Polytechnic Society.—How Cornwall Looks to the Visitor.—Problems of Tin-Dressing and China-Clay Mining.—Tungsten and the War.

Sooner or later every mining engineer makes a visit to Cornwall to see at first-hand the wonders of which he learned from the foreman at lunch-hour in the days when he was learning many things. Recently it was my good fortune to make the pilgrimage and see with my own eyes the hedges, fields, stone walls, tall stone pump-houses, and chimneys, and the buddles and rag frames in endless number and variety. I have stopped at Tabb's Hotel where the tin 'ticketings' are held, and I have descended into the depths in a shaft where levels are marked in fathoms instead of feet. The hard hat and the hand-made candles are strangers no more and I have lunched at the company-office on the good things of Cornwall. Anyone familiar with the little old towns hidden away in the valley of southwestern Wisconsin, or the tall stone-houses and massive mills of Gilpin county, Colorado (they print 'Notes from Gilpin County' in the local papers of Cornwall), anyone who has worked with the men at Grass Valley in California, will feel instantly at home in Cornwall. For that matter, from Lake Superior to Pachuca the Cornishman has left his mark on the land and an American miner from almost any district would find much that is familiar, as well as much that is fascinatingly strange, in the Old County. One difference would strike him at once, at least in these war times, and that is the small number of full-grown men in either mine or mill. Naturally they are largely at the front, for the ranks of the sapper have been recruited heavily from this district. Young boys and women are doing a proportion of work that looks odd to the American visitor. They seem, however, contented and happy, and much of the work is not hard. Tapping a tub of muddy water with a stick may be monotonous, but it is not labor too hard for the young. That is one of the phases of settling tin

concentrate that one sees on the dressing-floor. Incidentally, it may be mentioned that it calls for skill, and it is said that no mechanical tapper has been devised that gives just the right amount of regularity and variety to the blow. There are other queer but simple ways of doing things that one sees in the mills. Not the least interesting is the skillful work done with the vanning-shovel by the assayers, who use it in place of a chemical assay for most purposes. The vanning-shovel is much shallower than a gold pan, the work is done with a half-ounce sample, and the skill shown in separating the tin-tungsten minerals from the gangue is uncanny. At one large plant the mill-saving for a year checked within a trifle more than 1% of that calculated on the basis of vanning-shovel tests throughout the period. It is only, however, as a test of mill-work that the vanning-shovel is reliable. The chemical assay shows that a considerable amount of tin is lost by both shovel and mill. This loss is coming to be frankly recognized. At the recent meeting of the Royal Cornwall Polytechnic Society at Falmouth, W. H. Trewartha-James placed the loss "for purposes of discussion" at 30% and I noticed that no one

MAP OF CORNWALL, ENGLAND.

disputed the figure strenuously. One manager, who relies on chemical assays and samples the pulp from the stamps as in gold-mill practice, told me his saving was just about 70% but that he thought others did not do quite so well. Another, the manager of one of the most famous of the old mines, said frankly that he did not know what the loss was and doubted if anyone did. The matter was up for serious discussion at the meeting of the same society when Mr. Trewartha-James presented to the home-folk the paper on the 'Physical Characteristics of Cassiterite in Cornish Mill-Products' by the late J. J. Beringer, read before the Institution of Mining & Metallurgy last May. Beringer, who was Principal of the Camborne School of Mines, made a special study of the 200-mesh mill-products and concluded that below a certain definite size it was impossible to settle them in water economically and that it was here that the loss occurs. These conclusions seem to be generally accepted and it is now proposed to study (a) the size of the cassiterite particles in uncrushed ore, (b) methods of crushing to avoid sliming, (c) special methods of treatment, such as leaching, for treating the slime unavoidably made. A resolution was passed by the Polytechnic Society inviting the Institution to co-operate in a thorough scientific study along these lines. It is believed that something definite and practical will come from this work. Another similar proposal was that the Polytechnic take the lead in studying the technology of mining and preparing china-clay for the market. This has become a great industry in Cornwall, usurping a place formerly held by copper mining. The country consists of a great peneplaned upland of ancient phyllites and graywackes or 'killas' as they are locally called, above which rise monadnocks representing granitic stocks intrusive into them. In the killas around these stocks the copper veins are found and as these were worked down and into the granite, tin was found to replace the copper. On the other side of the contact and in the granite are great softened areas out of which the china-clay is dug. It is really granite, altered, probably by thermal solutions but possibly by weathering, and the clay is pumped rather than dug. Water is led down into the pits over the face of the bank, or is piped down and played against it in small weak streams, while the milky white pulp, containing about 2% solids, is pumped to the surface. The sand left behind is trapped in the pit and dug out by ordinary shovel and tram-car work. The clay-bearing pulp, which contains an amount of white mica equal, roughly, to the clay, is led through settling-troughs and pits till the mica is disposed of and then through earthen pipe-lines (as much as six miles) to the 'drys.' Here it is settled out of the water and finally dried over long furnaces roofed with fire-clay tile and in part with aluminum. Iron cannot be used in the process for fear of rust spoiling the color of the clay. These various methods and the chance of improving them were described by J. M. Coons and discussed at some length before the Society. The first impression on visiting a clay-pit is that the methods are crude and susceptible of much improvement, but they are effective and simple, and it is not so certain that many changes could be made advantageously. Stephen Vivian pointed out that it was all wrong mechanically to drop 98 tons of water into a pit and pump it out again to get two tons of clay, since in the end the quartz and refuse had to be mined anyway. A simpler plan would seem to be to mine the whole material and then wash out the clay at the surface. Possibly something of that sort may be done in time. The pit of the North Cornwall China Clay Co., which I visited, is about 6 acres in extent now, and 100 ft. deep. The clay extends at least another hundred feet in depth—how much more is not known. Temporarily the china-clay miners are much disturbed by restrictions on the shipment of material out of the country, but through a term of years the industry has grown handsomely. Another interesting paper was presented to the Polytechnic by J. H. Collins on the occurrence of tin and tungsten in Cornwall. Mr. Collins had listed all the localities in which tungsten had been found, a service particularly valuable just now when tungsten is in demand. The tungsten producers are under the control of the new Munitions Ministry, which has reserved the right to take all the product at a fixed price of 55s. ($13.20) per unit. As a matter of fact, they are allowed to supply regular customers so long as there is no shortage or delay of more than two weeks in Government orders. In this other direction the new system of controlled industries is working fairly well and the confusion of last winter is disappearing rapidly. England has been a land where every man's house was his castle and his shop was his fort but now that the whole strength of the nation is needed for war purposes the Government has taken possession and a new system of ordered and co-ordinated industry is being built up which will be worth much to the country in peace as well as war.

GOLDFIELD, NEVADA

ORE TREATMENT.—KEWANAS.

A 30-ton flotation plant is to be erected at the Goldfield Consolidated mill, where experiments have been under way for some time, devising a process to treat the gold-copper ores of this and other local mines.

Development in the Kewanas, where commercial ore was exposed near the shale at a depth of 840 ft., has shown that the true shale-contact zone has not yet been reached.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Juneau

The August return of the Alaska United is as follows: 270 stamps crushed 45,290 tons of ore yielding $72,240 from amalgamation and cyanidation of 964 tons of concentrate. The loss was $1311, construction costing $16,609. The ore yielded from $1.27 to $1.96 per ton.

The Alaska Juneau company is defendant in a suit by the administrator of the estate of R. Milatovich for $25,000 damages. It is alleged that the deceased fell into an uncovered winze, and died as a result of the accident.

ARIZONA

Cochise County

Extensive development continues in the Warren district.—— A new head-frame and double-drum electric hoist have been erected at the Uncle Sam shaft of the Copper Queen mine. A drift, 1600 ft. long, is to be started at 400 ft. depth between the Czar and Uncle Sam shafts. Good ore is being opened at 1600 ft. of the Sacramento division. Material for concreting this shaft is arriving, and work will soon be commenced. Good sulphide ore has been cut at 1100 ft. in the Lowell section. The Gardner is the busiest part of the property.

Lessees in the district are doing well, especially the Higgins Leasing Co.

Good copper ore is being opened from 200 to 800 ft. in the Shattuck-Arizona, also lead ore at the latter depth.

Gila County

At the Inspiration over 5000 tons of ore is being hoisted daily, the total for September being approximately 100,000 tons. Four sections of the mill are fitted with flotation machines of the Callow type, and four others will soon have the Inspiration type installed. Residue is conveyed to Ellison canyon, between the mill and smelter. At the power-plant one of the three 6000-kw. turbo-generators is working.

The Gibson mine is producing about $25,000 worth of copper ore per month. There are 81 lessees producing 30 cars of 20% ore per month. Other mines in the district are busy.

Greenlee County

The sequence of events concerning the miners' strike at Clifton are as follows: The general managers of the Arizona, Detroit, and Shannon companies replied to the leaders of the Western Federation of Miners on September 26, stating that a few agitators had led out many men who were satisfied with conditions, and that as long as the Federation had any influence in the district the mines and works would be closed indefinitely. In February this union called a strike at Miami, and another at Ray in July. According to Walter Douglas of Phelps, Dodge & Co., the Federation is trying to secure political domination of the State. Americans at Clifton receive the same wages as at other centres, as also the unskilled Mexican employees, but the latter cannot expect as much as the Americans. The wage dispute is only a wedge to unionize the districts.

On September 27 the governor of Arizona, W. P. Hunt, went to Clifton from Phoenix to investigate the dispute, the result of an appeal by the sheriff of the County. The Governor heard both sides of the trouble. The managers were insistent that the Federation be kept out of all arguments. The town is quiet. No pumps are working at the mines, so water is rising in them.

On October 2 the general managers of the three companies left by special train for Lordsburg, New Mexico, their destination being unknown. They feared personal violence, as the master mechanic of the Arizona Copper Co. was roughly handled, and the situation was grave. The militia is ready for any trouble that might arise.

It is stated that a minimum wage of $3.50 per day is demanded for miners, and $4.25 for mechanics, based on 13-cent copper, with an upward sliding scale for increased prices.

CALIFORNIA

Amador County

The Marsino mine at Volcano is to be prospected by diamond-drilling.——Ore from O. M. Henry's claim in this district is being hauled to the Central Eureka mill at Sutter Creek.

Butte County

The Noble Electric Steel Co. has bonded some manganese-iron ore deposits 1½ miles from Clipper Mills from the owner, G. W. Woolley. Ore will be tested at Heroult, Shasta county.

Eldorado County

Mining timber for Plymouth, Amador county, is being supplied by forests at Mt. Aukum, Fairplay, and Indian Diggings. A number of teams are busy hauling the logs.——In the suit over the lime deposits three miles north of Salmon Falls, the Holmes Lime Co. has received a clear title to them.

Kern County

A 40-hp. gas engine will probably be ordered for the Skidoo Mines Co.'s mill at Skidoo. Hot weather has affected the water-pipe, resulting in leaks and delays in treatment.

The Wild Rose mine is shipping 25 tons of antimony ore daily.

Nevada County

On September 30 the North Star Mines Co. paid 20c. per share, equal to $50,000. The total for this year is $150,000, and $4,687,040 to date.

The North Star company is to deepen the Providence shaft of the Champion property at Nevada City; the shaft, an incline, is being re-timbered and a new track laid. Sinking will commence from 1750 ft. A new electric pump and hoist are being installed. This shaft will eventually be the main outlet for the property.

Last week the Golden Center company at Grass Valley gave its employees a day off on full pay, and dined them well. This was on account of the end of threatened litigation and the opening of good ore.

At the Central-South Yuba mine some good copper ore is being developed at 100 ft. depth. A shipment has been sent to the Selby smelter.

Placer County

The Spreckels interests have bonded the Mason tract, containing limestone deposits, at Applegate. One thousand tons will be extracted for testing purposes.

Developments at the Herman mine at Westville continue satisfactory, and the 30-stamp mill is busy on good ore from the 300-ft. level.

Trinity County

Seattle people have been examining the asbestos claims of B. Kellogg, 12 miles from Hayfork.

It is reported in Montreal, Canada, that the Crown Reserve Mining Co. of Cobalt is negotiating for control of the Globe gold mine, which has produced $250,000 to date.

Tulare County

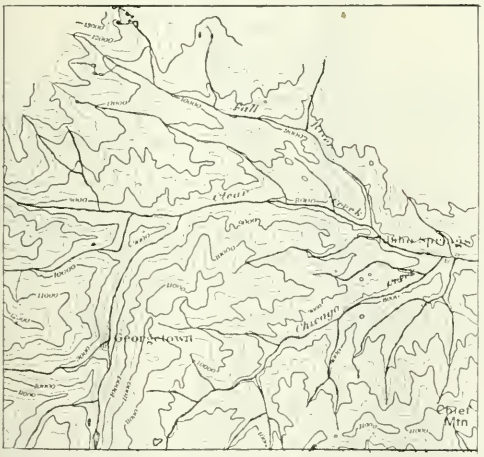
(Special Correspondence.)—The Mineral King district, an area of over 20 sq. miles, at an altitude of 8000 ft., and three miles from the Seqnoia National Park, is worth the attention of mining men with capital. It is an old district, but at present only a few men are working, most of the operations being done by W. F. Cord and T. J. Crabtree, who control 13 claims. At a depth of 30 ft. they are opening high-grade lead-zinc-silver ore. The area is highly mineralized. The lodes occur in limestone and quartzite. East and west of the district is granite. The properties are 38 miles from the railway at Lemoncove. A good automobile road is to be built next year.

Mineral King, October 1.

COLORADO

Clear Creek County

It is alleged that the water supply of Georgetown has been polluted by the residue from the Waldorf mill and cyanide-plant at East Argentine, and a temporary injunction against



TOPOGRAPHY OF THE GEORGETOWN-IDAHO SPRINGS DISTRICT. (U. S. G. S.)

the owners, the United Imperial Mines Co., has resulted in the works being closed. The company's vein in the Waldorf mine pinched recently, but now shows 24 in. of ore. It is 80 ft. long. Lessees at the Waldorf are getting satisfactory results.

Lake County (Leadville)

Leadville is busy at all points. Water in the Penrose shaft is two feet below the old 600-ft. level, from where all the larger stopes of the property were opened. The heaviest part of the pumping is finished. The shaft is in good condition, but the station has caved badly.

At the Bwlgocogh gold mine there are 25 men employed under S. G. Wightman. The mill is treating from 40 to 50 tons daily. The mine is worked by adits, and the main vein has been opened for 900 feet.

Ouray County

During August the Camp Bird mill treated 2787 tons of ore for a profit of $43,000.

Park County

Part of this county, near the boundary of Lake county, is attracting a good deal of attention. The roads from Leadville are not what they might be. Leadville people have leased several claims near the London mine.

Summit County

Several discoveries have been made in the Breckenridge district lately, and about 25 men are prospecting. No. 2 dredge of the Tonopah Placers Co. exposed some veins during its work.

IDAHO

Bonner County

Although the Priest River district is 30 miles from the nearest railroad, yet considerable activity exists. Miners think that the ore will stand the expense of this long haul.

Shoshone County (Coeur d'Alene)

The new 10,000-ft. aerial tram of the Interstate-Callahan is finished. It connects the mill with the Nine Mile branch of the Northern Pacific railway, a fall of 800 ft. Thirteen four-horse teams are now used to haul ore and concentrate; they will be dispensed with, and an estimated daily saving made of $250.

A 4000-ft. adit is to be driven into the Oom Paul mine, 1½ miles from Burke. The old 500-ft. adit in the Echo will be used.

A mill is to be erected at the Northern Light Mining Co.'s property on Pine creek, near Kellogg. B. G. Harmon is managing owner.

On October 4, the Bunker Hill & Sullivan Co. paid dividend No. 217, of $81,750. This makes a total of $16,527,750.

Over 60 mining and business men of Spokane visited the Coeur d'Alene districts at the end of last week.

The Bunker Hill & Sullivan company is making good progress in securing damage releases from property owners at Kellogg, in connection with the smelter to be erected there.

When several alterations have been made at the National copper mill, about October 15, the plant will start again. The bins are full of ore, and recent developments have exposed a large quantity.

The Ray Jefferson company is to construct a 250-ton mill next spring to treat the zinc ore being opened. David C. Smith is president at Missoula, Montana.

A shoot of high-grade zinc-lead ore has been cut in the Little Pittsburg on Pine creek, owned by G. Smith.

During changes at the Frisco mill, the property will be closed. Recovery of the zinc has not been satisfactory.

The Northport Smelting & Refining Co. was organized at Wallace on September 25. The directors are as follows: president, Jerome J. Day; Edward Boyce, E. R. Knight, F. M. Rothrock, and Eugene R. Day, the latter being secretary. Overhauling of the plant in Stevens county, Washington, is making good progress.

MICHIGAN

The Copper Country

Up to the last week of September the shipment of copper by boat from the region was 25,000 tons greater than the same period of 1914.——The Calumet & Hecla sand dredge and regrinding plant is working at near capacity. Six additional Hardinge mills were started last week.——The electric haulage-plant on No. 36 level of the Franklin is working satisfactorily.——In the new Isle Royale mill a sprinkling system has been installed to cope with possible fires.——The burned shaft at the Centennial has been repaired, but the rock-house is only partly re-built.

On September 24 the White Pine mill produced 52,000 lb. of mineral averaging 70% copper, a record, but the plant was not at full capacity.

MISSOURI

Jasper County

Joplin was visited on September 26 by 2.4 in. rain, making 55.14 in. for the year. No damage to mines was reported, as was the case three weeks ago.

The wage question is being considered by mine operators of the district, and the schedule is based on the average basis price of blende. The owners are not taking into account the actual low basis price in settling the monthly average.

MONTANA

Granite County

The Granite-Bi-Metallic company, of St. Louis, operating at Philipsburg, is to meet and decide on the future of the property. There is said to be $300,000 on hand for work or dividends.——The Royal gold mine has been optioned to Chicago people. It is fairly well equipped, including a 20-stamp mill.

Silverbow County

As copper averaged over 17c. per pound during September, miners in the Butte district will receive $4 per day, instead of $3.75 in August.

A good deal of development is under way at the smaller properties at Butte, including the Butte and Great Falls, Emma, Eveline, Butte and London, Jennie Dell, Nettie, Tropic, Rainbow, and Tuolumne.

In the argument as to whether the Butte-Duluth company was bankrupt, Judge G. M. Bourquin of the Federal Court at Butte dismissed the suit of creditors. Wages due amount to about $40,000. Other creditors, owed $200,000, did not wish the company declared bankrupt. The company wanted a receiver appointed, which was done, but not to be declared bankrupt.

NEVADA

Esmeralda County

The estimated production of the Goldfield Consolidated Mines Co. in September is as follows:

Ore mined, tons	32,500
Gross extraction	$269,000
Operating expense	$159,000
Net realization	$110,000

Some rich ore has been discovered at 440 ft. in the Laguna mine of the company, near the most northerly point where profitable ore has been found in the property. Details are not available yet.

Humboldt County

At 1200 ft. in the Seven Troughs Coalition there is 18 in. of ore assaying $10,000 per ton. The previous day there was 8 in. of $5300 ore showing. A winze is being sunk below 1400 feet.

The Friedman adit at the Rochester Mines property is in 1030 ft., and is progressing at the rate of 15 ft. per day. At that point 7 ft. of $11 to $30 ore was cut on October 3. Other parts of the mine are looking well. The September output of the mill will be about $40,000.

Nye County

Mines at Tonopah last week produced 9496 tons of ore valued at $196,888.

At 1020, 1100, 1170, 1260, and 1350 ft. in the Extension a wide lode is being developed, up to 18 ft. at 1100 ft. The new thickener in the mill will soon be finished.——A raise above 1166 ft. in the Belmont is showing better ore than previously. ——The Tonopah Mining Co. did 454 ft. of new work during the week.

Storey County

On the Comstock the Ophir and Con. Virginia have completed installing plant at the 2700-ft. winze. A station is being cut at the bottom, from which cross-cutting will proceed. The Ophir is to sink a winze below 2500 ft. From this depth the Union Con. is extracting good ore. The Mexican and Sierra Nevada are working at 2500 and 2700 ft. and 2500 ft. respectively. At Gold Hill the Jacket-Crown Point-Belcher Mines Co. continues work at 1600 ft. of the Crown Point-Belcher incline.

UTAH

Beaver County

New York capital has taken a hand in development of the Majestic mine, which produces copper ore. One shaft is down 400 ft. in good ore, and will be deepened; while the Hoosier shaft will be sunk from 460 to 1000 ft. Some ore is being shipped.

Boxelder County

The American Metal Co. has secured an option on the property of the Lake View Mining Co., at Promontory point, near Great Salt Lake, 24 miles west of Ogden. The price is said to be about $625,000. The mine contains high-grade zinc ore, and 48 cars have been shipped since last spring, returning up to $18,000 per car.

Juab County

The Tintic district produced 129 cars of ore last week.

Construction of the Tintic Milling Co.'s 300-ton plant is employing 75 men. It is hoped to complete it in January. Ore from the Knight mines, lessees, and dumps will be treated, using the Holt-Dern and Knight-Christensen processes.

At a depth of 40 ft. a shaft at the Yankee Consolidated cut ore, and a drift shows 5 ft. assaying 120 oz. silver, $8 gold, and 37% zinc. The discovery is the cause of considerable comment at Tintic.

Lessees at the Gemini shipped 1500 tons of $25 ore in September. The company has lowered the water to 1700 ft. depth.

CANADA

British Columbia

According to Oscar Lachmund, general manager of the British Columbia Copper Co., $1,000,000 will be spent in development and plant at its properties. A 2000-ton concentrating-plant will eventually be erected at the Copper Mountain mine, driven by a large power-plant at Coalmont or Princeton, and possibly a 9-mile aerial tram. Reserves at Copper Mountain are estimated at 8,000,000 tons of 1.75% copper ore. Extensive diamond-drilling has been done, and regular development is soon to commence. Three drills at present are boring 33 ft. each daily. At the Greenwood smelter one furnace is reducing 860 tons per day, including some custom ore.

Tests having been made of the Silver Hoard ore, near Ainsworth, a 50-ton concentrating-plant is to be erected. A power-plant is to be built on Cedar creek.

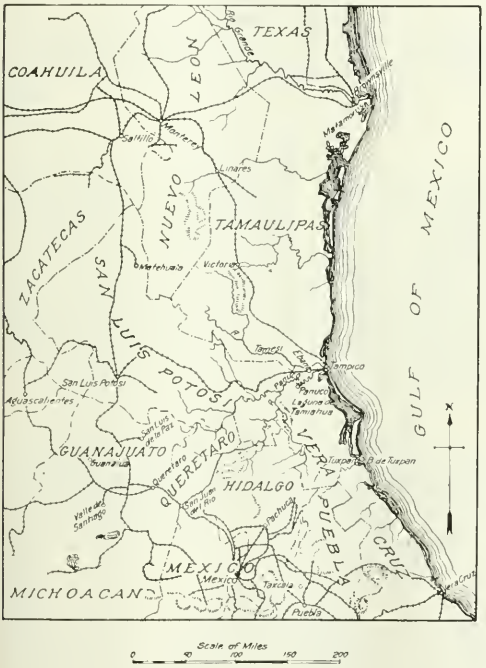
MEXICO

(Special Correspondence.)—Mining conditions are much improved in comparison to those of a few weeks ago, according to H. H. Allison, superintendent of transportation for the American Smelting & Refining Co. in Mexico. Mr. Allison came here from Chihuahua and Parral, *via* El Paso, a few days ago, on his way to visit Monterrey, San Luis Potosi, and other interior towns and mining districts of Mexico, as soon as train service is re-established. He says that as soon as he can make an inspection of the various plants of the A. S. & R., and provide means for supplying them with fuel and ore, they will resume operation. The recent exodus of American smelter employees and mining men from the Villa territory in Chihuahua caused the Company to shut down its smelter at the city of Chihuahua. The smelters at Monterey, Matehuala, and Aguas Calientes were closed some time ago, but Mr. Allison says that they will all re-open in a short time, and if the railroads are able to handle the fuel, the plants will be operating full time within the next 30 days.

Laredo, Texas, October 1.

The oil region of northwestern Mexico is discussed by V. R. Garfias in Economic Geology for April-May. The paper covers 28 pages, dealing with the topography and water supply, geology, origin of the oil, development, market conditions, production, transportation, storage facilities, refineries, and future development. Little has been published regarding the geology and occurrence of oil in Mexico. This paper is based on personal investigation by Mr. Garfias. The greater part of the petroliferous area lies in the state of Vera Cruz, only a northwest fraction being in San Luis Potosi. The centre of supplies for the oilfields is Tampico, where loading facilities are excellent. The oil area is from 20 to 40 miles south of Tampico. Transport of supplies is facilitated by estuaries and

streams. The first wells were drilled in 1882 near San Juan Bautista. The estimated output in 1914 was 27,000,000 bbl. Lack of adequate means of transporting oil from the wells to market has hindered successful operation of entire districts. The quality of the oil, and the distance of the field from Tampico and Tuxpam are factors controlling transport of the oil. The Ebano and Panuco districts' oils cannot be economically pumped through pipes. The former is used for asphalt and fuel by the Mexican railroads. The Panuco oil, however, is exported, and has to be barged about 60 miles by river to Tampico, where it is stored before delivery to tank steamers. On account of its viscosity this oil has to be heated twice. From the Huasteca and Portrero fields the oil is pumped to



PART OF MEXICO, SHOWING OILFIELDS.

Tampico and Tuxpam respectively through 8-in. pipes. Large tank-steamers are loaded in quick time, especially at Tampico. Storage facilities of the region totals 15,000,000 bbl. There are refineries at Tampico. Mr. Garfias regards the Mexican oil industry at present as only in its infancy.

In Bulletin 104 of the A. I. M. E., L. G. Huntley of Pittsburg, also discusses the Mexican oilfields in 41 pages. The history of development and production are dealt with, details of operating companies given, and geology and future are discussed. Potentially Mexico is thought to be the second greatest oil-producing country in the world.

In the same publication the Furbero oilfield, lying in the gulf coastal plain of Mexico between Tampico and Vera Cruz, in the state of Vera Cruz, is described by E. Degolyer. The deposit is of a type hitherto unknown. The area was one of the earliest known oil regions in the Republic. It is mostly covered with dense tropical jungle and a mantle of soil resulting from centuries of vegetable decay. The oil occurs in commercial quantities in igneous and metamorphosed rocks.

Hidalgo

During August the Santa Gertrudis made a profit of $25,000 from 13,338 tons of ore.

PERSONAL

C. S. Herzig is in Colorado.

H. H. Webb is at Los Angeles.

Ernest R. Woakes is in Spain.

Ben. S. Revett has gone to New York.

C. T. Durell has returned to Los Angeles.

John B. Hastings has been on a visit to Pittsburg.

R. M. Raymond has gone from El Paso to New York.

Philip R. Bradley has returned to Treadwell, Alaska.

J. Parke Channing is expected shortly in San Francisco.

Desaix B. Myers has returned from Colorado to Los Angeles.

H. L. Payne, of Baverstock & Payne, is at Yerington, Nevada.

G. Hildick Smith is now manager of the Ferreira Deep, on the Rand.

R. B. Lamb now has his office at Room 1615, 27 Cedar street, New York.

L. B. Eames is now mill-superintendent to the Hollinger Gold Mines, at Porcupine.

Corey C. Brayton has returned to San Francisco from a season's work in Alaska.

John R. Farrell is directing work at the Dean mines, near Battle Mountain, Nevada.

William Tr'ran left San Francisco on October 3 for New York, on his return to London.

Paul Selby, formerly at the Ferreira Deep, has been appointed manager of the Nourse Mines, at Johannesburg.

S. R. Coghlan has returned from Peru, having resigned as assistant superintendent at the smelter of the Cerro de Pasco.

J. D. Connor, representing the South Australian government in an enquiry into the leaching of copper ores, is now in California.

R. H. Stewart, general manager of the Consolidated Mining & Smelting Co., British Columbia, has been to Ottawa in connection with the zinc smelter to be erected at Trail.

A. L. Queneau has received the Distinguished Conduct Medal and also the French Cross of War. His eyes were injured while fighting at Ypres, but he has fortunately recovered.

George H. Garrey, of New York, formerly with the U. S. Geological Survey, has just completed a geological study of the Merger Mines property and surrounding territory at Goldfield, Nevada. His report will form the basis of future development plans of that company. Willis Lawrence has been appointed general manager for the Merger company.

Schools and Societies

The two weeks' field work in geology required of the students in mining and metallurgical engineering at the Carnegie Institute of Technology, Pittsburg, was conducted in the anthracite region of eastern Pennsylvania, in the vicinity of Hazleton, and at Franklin Furnace, New Jersey, during the early part of September. The party was in charge of Charles R. Fettke.

The Yale Engineering Association has recently been organized among graduates of Yale University. The present membership is nearly 500. Any Yale graduate is eligible, but those who are engaged in engineering pursuits are naturally more interested. The object is to assist work at Yale, and establish helpful relations between Yale engineers. The first meeting will be held at New Haven early in November. The secretary is R. T. Dana, '96 S.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, October 7.

Antimony	32
Electrolytic copper	19
Pig lead	4.75—5.70
Quicksilver (per flask)	$90
Spelter	16
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	26

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, October 7.—Copper is quiet and easier, showing no change all the week; lead is dull but steady; zinc is erratic and weak.

COPPER

Prices of electrolytic in New York, in cents per pound.

May	13.97	18.71	Nov.	11.75	....
June	13.60	19.75	Dec.	12.75	....

Exports of copper during the week ended September 18 amounted to 13,495,959 lb., valued at $2,578,709. Of this, 4,158,697 lb. went to France, 4,092,010 lb. to Italy, 2,295,029 lb. to England, 1,166,080 to Russia in Europe, 1,120,318 lb. to Sweden, and 257,286 lb. to Holland. Imports totaled 3,139,266 lb., worth $468,293. Canada contributed 1,920,799 lb., Chile 521,800 lb., and Peru 395,445 pounds.

The production of Michigan mines in September was about 25,000,000 lb., the large properties yielding the same as in August. The Calumet & Hecla and its subsidiaries are at full capacity and no more crushing power is available. The Champion company is paying $2 per share, making $23 for the current year.

August outputs were as follows: Chino, 6,640,923; Nevada Consolidated, 6,201,858; Ray, 5,779,489; and Utah Copper, 15,966,543 lb. The first two were small decreases, while the latter two were increases of 1,300,000.

The Miami is now producing at the rate of 65,000,000 lb. per year, and should make a net profit of $500,000 over the $4 per share dividend.

In the year ended June 30, 1915, the Granby Consolidated's profit was $929,165, from 25,746,059 lb. sold at 15.87c. per pound. The two properties are now producing at the rate of 42,000,000 lb. per year, the full capacity.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Sept.	30	Aug. 25	47.08
Oct.	1	Sept. 1	46.77
"	2	" 8	48.20
"	3 Sunday	" 15	48.56

May	58.21	49.87	Nov.	49.12	....
June	56.43	49.03	Dec	49 27	....

The undertone of the silver market continues to be good. On October 2, $493,960, say 1,000,000 oz., was shipped from San Francisco to China. Stocks at Bombay, India, are large, and it is not considered likely that that country will buy much in the immediate future. It is thought in some quarters that the reduced amount of gold being sent to India should have a favorable effect on the demand for silver, but Bazaar purchases lately have been small. Imports of silver into England during August totaled £532,350 (5,500,000 oz.), and exports from that country, £686,475 (7,000,000 oz.).

The Calumet & Hecla company is now recovering a good deal of silver from the refining of its copper at Hubbell, Michigan.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Date.		Average week ending	
Sept.	30	Aug. 25	11.96
Oct.	1	Sept. 1	15.75
"	2	" 8	14.77

June	4.84	22.20	Dec.	5.40	....

On October 11 the New Jersey Zinc Co. pays an extra 2% dividend. In August the Butte & Superior made $4.50 net per share.

Continuous rain has affected production in the Missouri-Kansas-Oklahoma zinc region. Prices for ore were stronger during the week ended October 3. The output was 6719 tons blende, 348 tons calamine, and 969 tons lead, averaging $80.57, $53.28, and $51.08 per ton respectively. The total value was $610,549.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			Week ending	
Sept.	8	95.00	Sept. 22	90.00

June	30.72	40.26	Dec.	33.60	....

On October 6 tin was strong at 32.75 to 33.25c. In London it is £151 7s.6d. to £152 15s. per ton.

MINING DECISIONS

Oil Lease—Payment of Rentals

Where an oil and gas lease provided for rentals of "50 cents a day until the well was commenced," these words were held to fix the rate and not the time of payment, and payments at reasonable intervals for default in drilling the well were sufficient to preserve the lease against forfeiture.

Smith *v.* Steele (Kansas), 150 Pacific, 519. July 10, 1915.

Oil Lease—Recovery of Rentals

Under an oil and gas lease providing for stipulated rentals in lieu of royalties if the lessee fails to drill wells, the lessor is entitled, upon failure of the lessee to pay the rentals, either to forfeit the lease or to waive forfeiture and sue for the rentals.

Cohn *v.* Clark (Oklahoma), 150 Pacific, 467. June 29, 1915.

Gas Lease—Assignee's Liability for Royalties

Where an oil and gas lease provides for an annual royalty on the gas produced and marketed, and the lessee operates the lease, marketing the gas for a portion of the year, and thereafter assigns the lease, the assignee, in the absence of a special contract, is not liable for the royalties accruing on wells the product of which was marketed prior to the assignment, regardless of when the royalties became due and payable, but is liable for such royalties as may accrue during the time he markets the product.

Columbus Gas & Fuel Co. *v.* Knox County Oil & Gas Co. (Ohio), 109 Northeastern, 529. October 13, 1914. (Not previously reported.)

Mining Locations—Conveyance—Warranty

An option agreement was made for the purchase of a certain group of mining claims—some patented, others unpatented—and deeds of conveyance were placed in escrow. After some payments had been made and development work done by the intending purchaser, the Government refused a mineral patent to a number of the unpatented claims on the grounds that the minerals in the ground had been exhausted. Thereupon the purchaser brought suit to rescind and recover payments already made on ground that the vendor had failed to make title. Held, that the parties in dealing with unpatented claims were dealing solely upon the basis of a possessory right subject to defeasance by the Government, and that there was no breach of warranty.

Trinity Gold Dredging & Hydraulic Co. *v.* Beaudry (California), 223 Federal, 739. May 24, 1915.

Annual Labor—Forfeiture by Co-owners

In 1910, E. Thompson, together with Thomas W. Pack and others, located 175 placer mining claims on the potash deposits at Searles lake, San Bernardino county, California. In 1914, Thompson served upon Pack and the other co-owners the notice of forfeiture provided for in Section 2324, Revised Statutes, for failure to contribute to the expense of assessment work. Thereupon Pack and the others sued for an injunction restraining Thompson from declaring the forfeiture, alleging that the notice was insufficient on its face, as it showed that Thompson himself had only spent $5600 in assessment work during the years 1911 and 1912, whereas $35,000 was required by the statute. Held, that the injunction should issue. A co-owner is entitled to declare a forfeiture under the provisions of Section 2324 only when he himself has fully complied with the requirements of the statute in performing his annual labor on the claims.

Pack *v.* Thompson (California), 223 Federal, 635, 641, 642, 643, 645. May 24, 1915.

BOOK REVIEWS

Manual del Ingeniero. Por John C. Trautwine, revisado por John C. Trautwine, Jr. y John C. Trautwine, 3rd. Traducido de la 19a edición (1913) y convertido al Sistema Métrico, por A. Smith. P. 1272. Ill. Paris. Casa Editorial Garnier Hermanos. Received from Trautwine Company, Philadelphia. For sale by the Mining and Scientific Press. Price, $5.

This is a translation of Trautwine's remarkably useful handbook for engineers. The publication of this Spanish 'Trautwine' places the Spanish-speaking engineer in touch with the great progress made by the English-speaking engineers and will be of great benefit to both. The typography and arrangement is the same as in the English edition. An excellent feature is that all weights and measures are given in both the metric and the English system. It hardly seems possible that such experienced publishers could issue this handbook without an index, but such is the lamentable fact.

The Mineral Industry. Edited by G. A. Roush. Volume XXIII. P. 998. Ill., Index. McGraw-Hill Book Co., Inc., New York, 1915. For sale by the Mining and Scientific Press. Price, $10.

Recent enquirers for this valuable annual work of reference and study of a great industry will be pleased to know that it is to hand. It was thought that the conditions existing would have curtailed the scope of the book, but we find that beyond the fact that the War made it difficult, and in some instances impossible, to obtain data, the number of pages is only twelve less than the previous volume. Metals and minerals are discussed alphabetically as usual, statistics are on previous lines, and leading journals have been drawn on for current technology. The lists of State Geologists and State Mine Inspectors will be found useful to those requiring information on progress in the States. 'Readjustments in the Mineral Industries,' an introduction by George Otis Smith, director of the U. S. Geological Survey, is in line with his 'Our Mineral Reserves,' how to make America industrially independent, published soon after the War started last year. The chapters on copper, gold and silver, lead, and zinc, of 126, 57, 94, and 35 pages, respectively, total a little less than those in Volume XXII, but are replete with the latest data and treatment processes. Great interest is now being taken in the rarer minerals, as many are not available from foreign sources, and those connected with non-metallic products will find the latest in this work. Important new chapters are as follows: 'The Flotation Concentration of Ores,' 'The Smoke Problem in the Mineral Industries,' and 'Refractory Materials.' The first is merely a summary of this new system of treatment, and current articles in the technical journals, such as the Press is publishing, must be read to keep up to date. Smoke and fume are dealt with by an expert, F. G. Cottrell. Fifty-one well-known engineers contributed to the varied information in the volume.

Mineral Resources of Minas Geraes (Brazil). By Albert F. Calvert. P. xi., 100. Ill., maps. Spon & Chamberlain, New York, 1915. For sale by the Mining and Scientific Press. Price, $2.

Brazil is rich in iron resources; nearly half of the book is devoted to repeated descriptions of these thinly embedded hematite and magnetite deposits. The total amount of iron ore available is enormous; individual deposits contain hundreds of millions of tons, while the whole district contains many billions of tons and "probably not far short of the total reserve of available ores in the Lake Superior region today (1911)." This is the statement of the author, but we find in 'Mineral In-

dustry' for 1913 that the iron ore deposits are estimated to contain 7500 billion tons, or three times the tonnage credited to the Lake Superior region; the quality is said to be better. In spite of these vast resources of iron ore of the finest quality, the production of iron in Brazil is so small that it is not mentioned in any of the ordinary works of reference. The book also treats of the gold mines of Minas Geraes; the most important mine is the Morro Velho of the St. John del Rey company; this mine has been worked continuously since 1834, producing 5,590,608 tons of ore with a gold yield of $54,771,375, from which $11,166,471 has been paid in dividends. The diamond and mica mines are briefly mentioned. We note an error in the statement that the mica mines in India are from 35 to 70 miles from a railway; those of Nellore are only a few miles away, and as the country is level, transport is cheap. The absence of an index, table of contents, parallels of latitude and longitude on the maps detract from the value of the work. In a book written for English readers an explanation should have been given of the monetary units employed; a bibliography should have been added. We find the book exasperating. The author evidently knows much about the subject and conld have easily written a valuable work instead of this meagre sketch. The 118 photographs and 10 maps are fully as interesting as the text.

UNITED STATES MINING STATUTES ANNOTATED. By J. W. Thompson. Bulletin 94. Law Serial 4. In two parts: (1) 'Sections and Statutes Relating to Metalliferous and Coal Mining'; and (2) 'Miscellaneous Mining Subjects.' P. 1772. Index. U. S. Bureau of Mines, Washington, D. C. Orders should be sent to the Superintendent of Documents, Government Printing Office, Washington, D. C. Price, $2.50 for cloth binding. Not sold separately.

This bulletin is a compilation of all sections of the United States Revised Statutes and of all acts of Congress relating to mines, mining, mineral lands, and the mining industry on the public lands. It is intended for persons engaged in mining enterprises that come within the scope of Federal mining laws and as a guide as to the determination of mining rights and duties. It shows the status of every Federal mining law, both laws relating to metal mining and those relating to coal, oil, and phosphate, and to mining on public, Indian, and railroad lands.

The bulletin relates only to the United States mining laws and does not include any of the laws of the different states in regard to mining. Another bulletin which the Bureau hopes to print in the future will contain the state laws.

In addition to the Revised Statutes and the acts relating to metal, coal, and oil and gas, acts relating to the following subjects, as they bear upon the mining industry are included: Alaska, Indian Lands, Lead Mines, Philippine Islands, Pipe Lands, Railroad Grants, Rights-of-Way, Salines and Salt Springs, Settler's Relief Acts, State and Public Grants, Stone Lands, Timber Cutting for Mining Purposes, Town Sites, Tunnel Acts, and Withdrawals.

All sections and acts are annotated. These consist of abstracts of decisions of all courts and public officers wherein any of these sections or statutes are explained, construed, and applied. The annotations are arranged under each section or statute with appropriate title lines in definite order, and consist of plain propositions of law, and point out how the courts have cured many defects, made clear the uncertainties, and aided in the practical application of these statutes. The large number and wide range of these decisions show that the practical value of the mining laws depends on their present status as established by the courts.

The preparation of these annotations involved an examination of more than 2000 volumes of reports of various courts and public officers. The work is indexed and any desired subject may be readily found. The work on this bulletin has been so expensive that it has been necessary to place the above price on it.

RECENT PUBLICATIONS

FAUNA OF THE SAN PABLO GROUP OF MIDDLE CALIFORNIA. By Bruce L. Clark. Vol. 8, No. 22. P. 188. Charts, 71 plates. University of California, Berkeley, 1915.

RESULTS OF THE INVESTIGATION OF SIX LIGNITE SAMPLES OBTAINED FROM THE PROVINCE OF ALBERTA. By B. F. Haanel and John Blizard. P. 110. Ill., charts, index.

ANNUAL REPORT OF THE MINISTER OF MINES OF BRITISH COLUMBIA FOR 1914, with the report of the Bureau of Mines by the provincial mineralogist, William Fleet Robertson. P. 541. Ill., maps, index. Victoria, 1915. This publication is of great value to all interested in mining in the Dominion.

MOTOR-CYLINDER LUBRICATION. By G. S. Bryan. Reprint from Journal of the American Society of Naval Engineers. P. 14. Illustrated. A study of the conditions under which the lubrication takes place, and of the characteristics of motor-cylinder oils that determine their suitability for these conditions.

U. S. Bureau of Mines, Washington, D. C., 1915:

NOTES ON MINERS' CARBIDE LAMPS. By James W. Paul. *Miners' Circular* 18. P. 10. This is a useful paper, and as acetylene lamps are increasing in use it should be secured by miners and others. An abstract appeared in the PRESS of October 2.

RULES AND REGULATIONS FOR METAL MINES. By W. R. Ingalls, James Douglas, J. R. Finlay, J. Parke Channing, and John Hays Hammond. Bulletin 75. P. 296. Index. The code of mining rules that has been finally drafted by this committee is the co-ordination of the experiences, opinions, and suggestions of a great many men who have assisted the committee in an advisory capacity and as directly employed aids. The former have included many engineers actively engaged in practice, members of professional societies, and members of the bar; the latter have included members of the regular staff of the Bureau of Mines and of the personal staffs of members of the committee. The committee has sought to obtain many points of view and to summarize many experiences. The draft that has been prepared is not offered as the last word upon this subject. There are many phases of this subject with which the committee has been unable to deal thoroughly. The work is thought to be useful under three main heads: (1) as a basis for State legislation; (2) as a basis for private systems of inspection; (3) as a collection of simple rules for the guidance of everybody engaged in mining.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., REQUIRED BY THE ACT OF AUG. 24, 1912,

of MINING and Scientific PRESS, published weekly at San Francisco, California, for October 1, 1915.

Editor—T. A. RICKARD, San Francisco, Cal.
Managing Editor—T. A. RICKARD, "
Business Manager—C. T. HUTCHINSON, "
Publisher—DEWEY PUBLISHING CO., "

Owners: (If a corporation, give its name and the names and addresses of stockholders holding 1 per cent or more of total amount of stock.)

T. A. RICKARD, H. F. DEXTER, San Francisco, Cal.; LEWIS T. WRIGHT, London, England; J. PARKE CHANNING, J. F. KEMP, New York City, N. Y.; L. S. AUSTIN, Salt Lake City, Utah; PHILIP ARGALL, Denver, Colorado.

Known bondholders, mortgagees, and other security holders, holding 1% or more of total amount of bonds, mortgages, or other securities: Wells Fargo Nevada Nat. Bank, San Francisco, Cal. C. T. HUTCHINSON, Business Manager.

Sworn to and subscribed before me this 30th day of September, 1915.

[SEAL.] (signed) HENRY B. LISTER,
Notary Public in and for the City and County of San Francisco, State of California. (My commission expires Feb. 1, 1918.)

EDITORIAL

T. A. RICKARD - Editor

PIG-IRON production in the United States during September reached a total of 2,852,561 tons, the highest recorded; the previous best being in February 1913.

THE $500,000,000 loan to the Anglo-French governments should provide at least $50,000,000 for purchase of base metals, more particularly copper and zinc, to be used in the manufacture of munitions.

BUTTE miners are sharing in the profit made by the mining companies, their wages being modified in accordance with the market-price of copper. In August the rate was $3.75 per shift, but in September it was increased to $4. This arrangement is in accord with the Anaconda company's policy of being fair to its employees. It is also a sign of the times.

FORTUNATELY the San Francisco *Chronicle* is not widely read in the Yukon, otherwise the winter gloom of that celebrated mining centre might be deepened by reading of "Dawson City, Alaska" in the columns of a paper published in the midst of the intelligent community by the Golden Gate. Our local contemporaries should study geography. The *Bulletin* lately described the Pyramids as "a range of mountains between France and Spain."

EVERY reader of this paper will find it worth his while to study our Metal Market Review, sent from New York by an independent observer thoroughly in touch with the trade. In his letter this week our correspondent refers to the preference now given to electrolytic copper, as against the old fancy for Lake copper, which used to be considered indispensable for the manufacture of products requiring penetrability. His report on zinc is encouraging to the miner.

ALUMINUM is gaining in popularity owing to the increasing use of it during the War. It is used in the making of a great variety of articles in the soldier's kit, such as canteens, utensils, and conveniences for the pocket. The metal is used increasingly for parts of automobiles and aeroplanes. After the War, those who have become acquainted with aluminum will employ it for other purposes; thus the War is assisting to advertise the metal. France, Great Britain, and Switzerland are important producers, but the United States ranks first. It has been predicted that the world's production in 1915 will be 110,000 tons, which is approximately equal in weight to Michigan's annual output of copper, but more than treble in volume. Aluminum dust is also being employed as a precipitant of the precious metals from cyanide solutions.

RECOGNITION of Carranza will cause Villa to be less careful to placate public sentiment, so that depredations on the mines and smelters of northern Mexico may be attempted during the next few weeks. Already Villa's representative at Chihuahua has ordered the local smelter to reduce the ores confiscated, that is, stolen, from foreign mining properties. But, with the support of our government, the predatory activities of Villa should soon be brought to an end.

MANGANESE has risen in price mainly on account of the cessation of imports from the Caucasus, where are the purest deposits of the ores of this metal. For the making of ferro-manganese an ore not poorer than 42% in manganese and containing not more than 12% silica is required. In California the black oxide is found in the radiolarian chert beds of the Franciscan series, but the deposits are relatively small and they tend to become increasingly silicious as they are followed below the surface. Ferro-manganese is being made on a small scale by electric smelting at Heroult, in Shasta county, where small masses of pure magnetite are available, as well as reasonably cheap power.

OUR excellent contemporary, *The Canadian Mining Journal*, publishes a most useful article on the structural features of the Porcupine ore deposits by Mr. Alfred R. Whitman. His analysis of the conditions modifying the distribution of the gold is of practical service and should be appreciated by those at work in the district. We note with particular interest that Mr. Whitman concludes that no evidence exists, although he has sought for it, to suggest the deformation or bending of the quartz since it was precipitated in the fractures now constituting veins of gold ore. Where subsequent movement has taken place, the quartz is crushed. Such plasticity as may have permitted further compression since the time when the quartz was deposited is to be credited to the schist, which has been deformed unevenly, producing the local variations of structure that Mr. Whitman describes lucidly.

MORENCI and the neighboring mining districts of Clifton and Metcalf are the scenes of a thinly disguised outbreak of anarchy, in which the sinister figure of Moyer looms bigger than that of the Governor of Arizona. We do not know all the rights of the quarrel, the miners may have legitimate grievances, but we sympa-

thize with the managers in their refusal to negotiate with Moyer and his criminal association. The flight of the three managers from their posts of duty to El Paso cannot be imputed to lack of physical courage; we accept the explanation that it was done to remove an incitement to violence that would have involved innocent residents, now terrorized by the Western Federation of Miners. The Governor, as is usual in such cases, is paralyzed by political considerations and is a shuttlecock between the contending factions. The suggestion to refer the matter to the department of Commerce and Labor is a confession of ineptitude, but it may prove the best solution of the difficulty. If that is done, we may hope for an impartial inquiry.

MAGNESITE is one of the many mineral products for which an increased domestic demand has been created by the disturbance in Europe. Before the War the United States was consuming 200,000 tons of this substance, obtaining 120,000 tons from Austria and 60,000 tons from Greece. Until April, shipments of Austrian magnesite were obtained on Italian vessels sailing from Trieste, but the trade has now ceased. Imports from Greece are likewise no longer available as heretofore. Hence the better market for the California product. We may add that the Greek magnesite is used mainly in plastering and fire-proofing, it being too infusible for metallurgical processes, for which purpose the Austrian product is better adapted by reason of an admixture of iron oxide that renders it less refractory and therefore more suitable for fusing into a solid furnace-bed. The ordinary price for dead-burned magnesite as delivered in New York or Chicago is $20 per ton; now the price is $25 in California, making the price of the product about $37 when delivered in the East. On another page Mr. S. H. Dolbear gives some details concerning magnesite mining in California.

UPON another page we publish part of a stirring address delivered by Mr. F. H. Newell at the inaugural meeting of the American Association of Engineers held at Chicago on September 14. True to the Anglo-Celtic tradition, this new departure was formally launched at a dinner, followed by speeches by various representatives of the profession. In consequence, a convention is to be held at Chicago in December. What may be the exact purpose of the new organization is not clear from the information as yet to hand. We note a reference to "the great problem" that is to be solved. Perhaps Mr. Newell will tell our readers what it is. Is it co-operation with a view to fraternal benefit, that is, insurance against ill health or lack of work? The best thing that can be said for the movement is that Mr. Newell apparently is at the head of it. As chief of the Reclamation Service he won a great reputation as a capable and broad-minded executive. We are in sympathy, of course, with the aspirations of the engineering profession and realize that it should exercise a greater influence in the modern community, but we confess to a certain tiredness of associations and societies without definite aim or purpose, serving mainly as an excuse for an occasional banquet at which the oratory and the gastronomy are equally swamped in rich sauces of a deappetizing character. What is the new association going to do for the profession?

Rolls and Ball-Mills v. Stamps

The passing of the stamp-mill has been predicted so often during the last twenty years that one is compelled to discount any new threat to consign that ancient crushing device to the scrap-heap. Various machines have had their day of pride, only to be relegated to the secondary function of re-grinding the product of the stamp-battery. In the treatment of low-grade copper ores of the disseminated chalcocite type there has been a notable development in the use of gyratory crushers followed either by rolls or by ball-mills, without the intervention of stamps. Of all the recent attempts to break away from the old methods, which came to us long ago from Hungary, the most important is that now being made at the big low-grade gold mines of south-eastern Alaska. At intervals we have recorded the progress of the colossal experiment by which the old Perseverance mine, in the hills behind Juneau, has grown out of all recognition into the Gastineau enterprise of the Alaska Gold Mines. In our issue of September 11, Mr. Robert S. Lewis described the main features of the scheme of exploitation, explaining how an ore assaying only $1.50 in gold is treated so that the precious metal is collected with the base-metal sulphides into two kinds of concentrate, one rich in galena, which is shipped to the smelter, and the other predominantly pyritic, which is re-ground previous to being subjected either to cyanidation or amalgamation for the extraction of its gold content. Thus the chief product of the mill is a gold-bearing lead concentrate, which undergoes roasting, at the smelter, before further reduction and disintegration of its valuable contents. The machinery employed to effect this concentration is modeled on the plant used in the treatment of the enormous copper deposit that constitutes the Utah Copper mine. Thus the Gastineau practice is based on the special experience of its promoters and engineers, Mr. D. C. Jackling, the late Albert F. Holden, Messrs. George O. Bradley, and Charles E. Bruff. In this issue we publish a detailed description of a plant of 1000 tons capacity, designed to perform the crushing precedent to such a scheme of concentration. The method seems logical, given the figures of yield and cost that are the first elements of the problem. In the case of these Alaskan mines, as of the famous disseminated copper deposits of Utah, Nevada, and Arizona, the engineer has a magnificent chance to apply his skill, for he is given an abundance of material, which, after all, is the first requisite to the devising of economical schemes of exploitation.

As our readers are aware, the Gastineau mine is next-door to the Juneau, a wide lode of gold-bearing slate traversing both of them. At the Gastineau the practice of the Utah Copper has been adopted in large measure, so that the chief crushing machine is the rolls; at the

Juneau the principal suggestion has been derived from the practice of the Inspiration mine in Arizona, hence ball-mills predominate. Across the strait called the Gastineau Channel, separating the mainland from Douglas island, is the Treadwell group of mines where stamp-milling of the orthodox kind has been applied successfully on a large scale for many years. The obvious contrast between the mills on opposite sides of the water provokes the query as to whether the Treadwell will modify its methods in the light of the later experience afforded by its neighbors. To that question we are able to reply that the management, which is known to be progressive, has not overlooked the opportunity of investigating the new departure in milling. Experiments with various ball-mills and with Deister tables are being made by the manufacturers of these machines, with the cordial approval of the mine managements, both at Treadwell and Juneau. The choice of plant-design is a matter of expediency, regulated in turn by tonnage. At the present time the Treadwell group is equipped for work down to a vertical depth of 3000 feet; if underground explorations justify development to 4500 feet, which will be the next stage, then it will become necessary to consider the erection of a mill adjacent to a central shaft. This means the choice of a consolidated and compact plant, replacing the five different mills, with their aggregate of 960 stamps, now at work, saving a large part of the miscellaneous labor required among the scattered units. The ball-mill gives a maximum crushing capacity at a minimum of space; for example, a mill 8 feet in diameter and only 6 feet long will crush 400 tons per day, and cover a surface about 14 feet square, while a stamp-mill of equal capacity will occupy a space more than twice as large. In both cases two-stage crushing is assumed. At present the ball-mill, as at Juneau, crushes to 40-mesh, in two stages, as against an average of 24-mesh reduction by ordinary stamp-mill practice at Treadwell. This compactness and finer crushing renders the ball-mill attractive, even if it cannot beat the stamp-mill in cheapness, for the old 300-stamp mill at Treadwell has been running during the annual flood-water period at a cost of only 13 cents per ton. Under the ball-mill we include the latest type of Hardinge, in which pebbles are replaced by steel balls; in fact, the ball-mill has developed from the Krupp and Hardinge machines, chiefly by aid of the greater toughness of manganese-steel and the use of subsidiary devices, such as the Dorr classifier. In the Gastineau mill the Garfield table is being used for a 'rougher' or preliminary concentrator, followed by the Wilfley; while the experiments at Treadwell point to one type of Deister table for rough concentration and another type of the same make for fine concentration. The main point is that a mill of 8000 tons daily capacity covers a vast space and involves an enormity of machinery, which means much miscellaneous labor; hence the effort to find machines that are compact and yet of big capacity. All of this effort to obtain maximum capacity on a minimum expenditure of money, while keeping the cost down to the established level, is necessitated in order to compensate for the rising price of labor and the higher expectations of capital. It bespeaks the progressive spirit that animates mining in the West—above all the willingness to dare, in order to learn something new.

The Mexican Government

On October 2 the Secretary of State, with the concurrence of the representatives of the governments of Argentina, Brazil, Chile, Bolivia, Uruguay, and Guatemala, decided to recognize Venustiano Carranza as the head of a *de facto* government in Mexico. In doing so the members of the international conference simply accept the logic of events, for the largest measure of military power in the distracted country south of the Rio Grande undoubtedly rests with the Carranzistas. Villa and his troops have been herded steadily north-westward, while Zapata and his followers have been driven out of Mexico City by the forces of the Constitutionalist party. That party was started in March 1913 when Carranza announced the so-called Plan of Guadalupe, soon after he had fled from Saltillo in fear of Huerta. At that time the First Chief of the Constitutionalists—as Carranza calls himself—was Governor of Coahuila, a state that adjoins Texas. To go back to the commencement of his career, we may note that Carranza began as a lawyer at Saltillo; he was the henchman of Miguel Cardeñas, for 16 years Governor of Coahuila. Cardeñas was a 'scientifico,' that is, an exponent of "scientific business," or, to be plain, systematized graft. Subsequently Carranza became an associate of General Bernardo Reyes, for many years Governor of the adjoining state of Nuevo Leon, at a time when the power of Diaz was declining. Carranza wanted to succeed Cardeñas in the governorship, but Diaz distrusted him, so he was made a senator and called to Mexico City. In the last hours of the old dictator's régime, in 1911, Carranza joined a revolutionary movement started by Reyes. When Diaz was drawn into exile and Madero became president the ambition of Carranza was fulfilled: he became Governor of Coahuila. That was in 1912. Reyes was shot at the beginning of the riot—in February 1913—that ended in the murder of Madero and the rise of Huerta to the presidency. Carranza refused to recognize the latter and fled to Guadalupe, where he published the revolutionary propaganda of the Constitutionalist party, cooperating with Villa until June 1914, when they separated, soon to begin a cat-and-dog fight that has lasted until now. Undoubtedly Villa's natural ability as a commander in the sort of warfare that has persisted in Mexico did much to bring Carranza to the front and the break with his chief lieutenant marks one of the weaknesses of the leader of the Constitutionalist party—his inability to inspire loyalty in his lieutenants. He is an obstinate and pompous man, of mediocre mental equipment, and without military talent. For the success of his later operations he is indebted mainly to Alvaro Obregon, who has been reported repeatedly as about to break with him. Now that Carranza has obtained recognition, and is assured of financial assistance, he will be better

able to hold his principal followers together, so that the military operations will decline in importance, thus throwing into the background his lack of ability in such matters, while giving him a better chance to exhibit his skill as a politician, in which respect he is not deficient. During recent months Carranza has been able to maintain martial rule over the richer part of the country, along the Gulf coast from Vera Cruz to Tampico, and inland to Mexico City itself, which has been repeatedly invaded and evacuated by various so-called armies under the leaders of different factions, until now it is again garrisoned by the Carranzistas. During the desultory guerilla fighting of the last two years the military forces of the revolutionary gangs have been worn down to mere remnants of their original strength, both as regards personnel and equipment. The country at large has been terrorized, ravished, and looted. Carranza and his officers have done their share of atrocities, but they compare favorably with Doroteo Arango Villa (his real name is not Francisco), a butcher's assistant and brigand, who committed his first murder at the age of 14, and Emiliano Zapata, a stable-boy and illiterate bandit, who has been allowed to over-run the southern vicinity of the capital for several years. The recognition of Carranza and his party is an unwilling concession to the logic of events. Carranza comes to office no cleaner than Huerta. The objection made to one applies to the other. Presumably the administration at Washington realizes that no leader can reach the presidential chair of Mexico with white hands. It remained only to make a choice of evils, in order that some semblance of order may be restored. Many of our readers will be inclined to question whether military intervention and the forceful control of the principal railroads would not have been a more effective means of pacification, and we think it likely that this may prove to be the ultimate solution of the problem, but meanwhile the new plan should be given a fair trial. Of course, an embargo will be placed on the export of arms or munitions across the border to those who must now be regarded as insurgents against the lawful government of Mexico, thereby making it increasingly difficult for Villa to maintain organized opposition. The new government will have to be financed so that it may establish itself firmly and also pay indemnities for damage done to foreigners. These financial arrangements are important. We hope that silver coinage will be restored, for that would not only help the mines to resume operations, but would serve as an incentive to peaceful work among the roving bands that have been the curse of industry for three years. The outlook is not without hope. It would be much more cheerful if the educated and professional elements in the population had asserted themselves in patriotic endeavor to restore constitutional government, instead of fleeing from the country and leaving the control of affairs to the illiterate and unruly. One cannot contemplate the recent history of Mexico without asking where are the men of Spanish descent and decent traditions? It is the Indian and the *mestizo* that has been on the rampage so long. They appear to be weary of it, and therein lies the hope that the Carranza government, now that it has won recognition and support, will be able to attract the better elements of the country in an effort to end the chaos of misrule. For that we wish most devoutly; no mining region affords better chances for the intelligent explorer and operator. In wishing better days for the unfortunate Mexican we wish renewed opportunity for the mining engineer.

Bubbles

Those who read the colloquy between the judge and the learned counsel in the flotation suit, as reported in an excerpt from the transcript of record that we publish in this issue, will find relaxation in reading the two following pages, in which our friend, Mr. Ben. S. Revett, tells about his first acquaintance with the bubble process 26 years ago in Oregon. With him it was indeed a bubbly performance, for it began with bubbles of air in an oiled pulp and concluded with carbon di-oxide in a clear liquid, also slightly acid, like Potter's or Delprat's method, but containing more alcohol than is needed in serious metallurgy. The pale amber liquid in which is dissolved the sunshine of the Champagne vineyards has ever been synonymous with the bubbles of pleasure. Man is borne to happiness as the bubbles go upward. If our metallurgists only knew as much about the physics of the bubbles of flotation as they do about the philosophy of the bubbles that enliven the juice of the grape, it would not be necessary for Judge Bradford to catechize Mr. Scott so earnestly. However, what man has done, man can do. The day will come when the flotation bubble will be pricked, as it were, and we shall know its true scientific inwardness. And when that happens, let us hope that the secret will be disclosed simultaneously to so many that the discovery will be described lucidly in the technical press instead of being seen as through a glass darkly in the gazette of the Patent-Office. Indeed, as we tread our mental way through the maze of patented obscurities, whether it be No. 793,808, No. 835,120, or the multitudinous other efforts to state facts without giving information, we find ourselves murmuring that "the earth hath bubbles as the water hath, and these are of them"—bubbles so numerous as to make not only a froth but a thick mist from which is condensed a murky stream of unending litigation. The attempts of patentees to obtain exclusive rights to the use of their fortuitous bubbles reminds us of the picture by Millais in which the boy sits gazing at an iridescent creation of his breath and wonders when it will burst. It is a far cry from the pretty boy to the portly figure of Mr. Criley at Baker City, but they are joined in the pursuit of the elusive film that catches the rainbow hues of hope. Mr. Criley's bubbles went flat long ago, but we are glad to think that those of his observer, who learned early to respect another man's hobby, are still rising cheerfully in the glass of time. We hope that they may prove to be so numerous and persistent as to compose a froth on which rich minerals may be conveyed to a safe haven of effective concentration.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Meetings and Discussions

The Editor:

Sir—Your editorial in the PRESS of October 2 seems to take a jaundiced view of the meetings of the International Engineering Congress. Were the banquets too much for you? You may be right as regards the meetings or meeting (I think there was but one?), of the mining section, where, as you point out in your editorial, most of the time was taken up in reading from manuscript long and dull papers, or in reading equally long and dull abstracts, and where the discussion was confined to a dispute as regards facts, impossible to ascertain except by an independent investigation that might easily cost some tens of thousands of dollars. There was another short discussion in which an algebraic error was discovered.

But whatever may have been the sad results of the meetings of the mining section, I wish to protest against your insinuation that the metallurgical sessions were not all that they should have been. Perhaps it is too strong a statement to say that these metallurgical sessions were ideal, but they were, at the very least, useful and informing—and not dull. The reason that these meetings were so good is that they were run on exactly the lines indicated in your editorial. The inexperienced chairman was avoided and in his place such parliamentary experts as Messrs. Butters, Clevenger, and Ricketts were selected. Next, preparation for the discussion of the papers was made by inviting engineers familiar with the subject to attend the meetings; they did attend and as a result the ensuing discussions were lively, and instructive. Perhaps the best discussion was on Laist's paper on 'Advances in Copper Smelting.' Indeed, under the exhilarating influence of good fellowship, and in exchange for valuable information, some unexpected disclosures of trade secrets were made by managers of large works. I heard several auditors remark that they never would have learned certain details had they not come out in discussion. Not that any harm was caused by these disclosures—far from it. All that happened was that the gates of secrecy were raised for a moment and a slight quantity of exclusive information was allowed to flow freely.

The error of wearying the audience by long abstracts or the reading of long papers was kept well in hand by chairmen and secretaries, who frequently saved valuable time by gentle hints to the speakers. Since much preparatory work was done to make these metallurgical meetings a success, and as all who attended seemed to think the meeting successful, I feel that your statements as to the inefficiency of the meetings ought not to go unchallenged and I wish to state that whatever may have been the character of the meetings of the mining section those of the metallurgical section were eminently successful and practically free from the faults that you have rightly condemned in your editorial.

JOHN WILLIAMS.

Refusal to Meet Miners

The Editor:

Sir—The general managers of the Arizona Copper, the Detroit Copper, and the Shannon Copper companies were arrested at Lordsburg, New Mexico, on October 2, on the charge of inciting a riot by refusing to negotiate with the officers of the Western Federation of Miners, and by leaving their mines at Clifton, Arizona, where several thousand miners are on a strike. Their action is held by the Arizona authorities to tend toward disorder and is deemed a felony under the laws of that State. After a hearing before the justice of peace at Lordsburg, the managers were released.

I have no desire to criticize the flight of the managers. It is, indeed, quite probable that they left the mines under positive orders from headquarters. Moreover, they knew all the conditions; their departure may have been prudent and commendable. Nor do I in any way wish to countenance any violence on the part of the strikers, or to support the Western Federation of Miners. I wish, however, to state clearly that I think, as a rule, mining operators make a great mistake when they refuse to meet the representatives of the miners. It may be that in this Clifton case such refusal may have been a mark of highest wisdom, but I doubt it. There is probably no method of irritation that is more effective in driving men to desperation than a refusal to listen to their complaints or to meet their representatives. Such refusal practically says to the miners that they are too insignificant or too vile to deal with, or else that the management has fully made up its mind and is deaf to argument. In fact, the refusal is nothing but a goad to stir men to desperate acts. So it has stirred men in the past, and so it will stir them in the future. It is stated on excellent authority that most, if not all, of the atrocities of the last Colorado strike might have been avoided had the operators consented to meet the miners.

In most cases of a refusal to meet the men it is argued by the management that such meeting will be in fact a

recognition of the Union and will serve no good end. I recently heard a manager who has long been in charge of a large corporation state that the men know what they want and the managers know what they are prepared to grant; so what is the use of a conference? This argument, if carried to its logical limits, would put a stop to most of the world's business, for what does most business consist of but conferences between men who wish to find a common meeting-ground? It is certainly not true to say that bodies of men that have once made up their minds may not afterward change them. A good instance to the contrary was the settlement of the anthracite strike in 1902; there was a deadlock, and the 147,000 miners on one side and the anthracite operators on the other could find no adjustment of their differences. However, the Commission appointed by President Roosevelt was able to find a method of operating the mines that has worked for thirteen years without the recurrence of strikes. I do not suggest that meetings between the operators and the miners are going to abolish strikes, but I do feel that it is a method that works for peace, and in these days of desperate strikes, where armed forces battle for days, it is the part of wisdom to try all the conciliatory measures possible. For my part, rather than refuse to meet the miners I would advocate inviting them to dinner and discussing difficulties over coffee and cigars instead of over machine-guns and bombs. Let us have peace.

HAROLD JAMESON.

Oakland, October 5.

The Prospector

The Editor:

Sir—Under the above heading in your issue of September 18, I read a communication in which your correspondent complains that too much caution is used by examining engineers when reporting on prospects. As one who has spent many years both as a prospector and an investigating engineer, may I offer some remarks on the subject.

I fear that your correspondent sees the subject entirely from the view-point of a prospector, and that he has not been placed in a position where he is responsible to an investor who places entire confidence in him by accepting his judgment, and by spending a large sum of money in following out his recommendations.

My own experience, extending over many years, has led me into the mining regions as a prospector, and often while seated around the camp-fire, I have joined in strong language at the shortsightedness of the investigating engineer who turned down our prospects, regardless of their worth, and indifferent to the apparent merits of the discovery. This is how it seemed to us at any rate.

But looking at the subject from the view-point of the investor, who risks his money in the new venture, can an engineer be too cautious? I think not, even though some of the greatest copper-producing mines of the present time were in earlier days turned down under expert advice.

It has always been my belief that the ability of an engineer to pass accurately on the value of a prospect requires just the same amount of skill and sound judgment, just as wide experience, and the use of as much caution as is demanded in the examination of a developed mine, if not more so, for he has not the developments of the mine to assist and guide him in forming an opinion as to the future possibilities of the discovery, and he must therefore decide from his experience in similar cases whether or no the prospect should be taken up or turned down. Every time he makes a mistake his employer loses money, and his own reputation suffers; therefore, caution, extreme caution should be his watchword, otherwise he may rest assured that, sooner or later, the employer will be broke, and the engineer discredited.

How many prospects develop into mines There are no statistics with which to answer the question, but everyone who has been connected with mining for any length of time knows that the percentage is very small, certainly not 1%, probably not even half of 1 per cent.

It should not be difficult therefore for your correspondent to appreciate why so much caution is used in the investigation of mines and prospects; it is not because the prospector is regarded as a faker—for he is not—but because good sound judgment demands caution in a business that contains risks no amount of foresight can wholly remove.

ERNEST G. LOCKE.

Rochester, Nevada, October 1.

The Editor:

Sir—I am particularly struck with the communication in your last issue from Mr. Richardson, and your comment thereon. There is no question but what the decadence of the prospector is largely due to his inability to 'place' a good prospect—when he finds one—to the fact that he must come up against the mining engineer, who will inform him, with lordly disdain for the prospector's humble opinion, that he must "do more development" on his claim before he can expect the syndicate, which this engineer claims to represent, to pay any money for the really intelligent selection that the prospector has made of ground still open in Uncle Sam's domain of mineral land, to say nothing of the hard licks he has put in for three, five, or ten years—in doing the necessary assessment work.

I have a consistent regard for, and sympathy with, the prospector and am pleased to learn that you are willing to "stand somewhere between him and the amateur," for it is my fixed opinion that there would not be so much of a wail throughout our mining territory in the U. S. over the "passing of the prospector" were it not for the frequently unfair attitude of capital (and I regret to say of my brother engineers also) toward the struggling man with the pick and shovel who makes discovery of mines, for the late comer to profit by at the rate of 100% to 1000% on his investment.

This does not mean that the prospector always has a true valuation of what he has discovered, for many of

them should be carrying a hod instead of mining, but it is certainly a fact beyond dispute that many of the men with whom you and I have "shared blankets and bacon" deserve far more than they have received.

I failed to participate in the discussion, some months ago, which ran through several issues of the PRESS and which elicited valuable opinions as to reasons for fewer and fewer men engaging in the business of prospecting, but I venture the assertion that mining, and particularly exploitation of new territory, is suffering because of the reward to the prospector not being commensurate with the effort put forth.

Classification and Fine Grinding

The Editor:

Sir—Metallurgists now fully realize the importance of classification prior to the fine grinding of ore. In order to obtain the maximum efficiency from tube-mills, it is necessary practically to eliminate all slime from the feed.

There are mechanical classifiers now in use that will separate (−200 mesh) slime from sand very efficiently, such as the Dorr, Esperanza, Akins, and Ovoca. Beyond this point, if one desires to separate a −100 or −60 product from the tube-mill feed, it is not efficiently done by the above machines. In fact, their makers do not claim to do so.

I believe in the short tube-mill, in sizes of 6 by 6, 8 by 8, and 10 by 10 ft. These are particularly suitable for gravity-concentration mills (intermediate grinding) in which the minimum production of slime is desired. No doubt, in many gold-milling plants where 'all-sliming' is not necessary, they would be far more economical than the 5 by 20-ft. tube-mill.

Oil-flotation and tin-dressing plants will find short tubes more economical and efficient than Chilean mills, long tubes, or pans for intermediate grinding.

However, a certain type of mechanical classifier is necessary for the short tube-mill that will separate a −60 or a −80 product from the feed in order to get the maximum duty or grinding result. A classifier that combines the results of the spitzlutten and mechanical screw or rake-classifier will produce the desired product. With such a machine one could deliver to the tube just that product plus 40% moisture that would pay to re-grind. Such a classifier would meet the requirements better than any one of the machines on the market at the present time.

I therefore offer for the consideration of mill-men the type of classifier shown in the inclosed drawing.

The Engineer Awakes

By F. H. NEWELL

*Now is the day of awakening of the engineer as a man and as a citizen to a larger realization of his duty to society in general, to his profession, and to himself in particular. He is not alone in this. The world-wide war has shocked into life many dormant conceptions and has opened the eyes of mankind to the larger claims of brotherhood. The horrors of the destruction of life and property and the ruthlessness with which the accumulations of centuries and the hopes of the future have been sacrificed is bringing about a reaction and is preparing the way for the growth of a larger human consciousness. The engineers in this peaceful country are not unaffected. Their occupation in a large part has been reduced and as a result they have been afforded time and need for thinking on these vital matters. They are getting fully awake to their part in the world's progress.

There is nothing really new in this awakening, except perhaps in the greater intensity and vigor of the accumulated forces at work. Life with its rhythmic character is a constant series of awakenings; we remain quiescent or sleep until hunger sharpens the appetite and forces a clearer realization of surrounding conditions. This is literally true at the present time. The hunger or threatened hunger of large numbers of professional men is causing them to note more keenly their surroundings and their relations to each other and to the public.

More than this the present century is that of organization. The zeal for the study of efficiency, the demand for larger and more effective organizations, the value of preparedness, all of these are being forced on the attention of the thinking man; he is seeing as never before the need of organization and of sacrificing some of his individuality in the interest of work for and with his neighbor.

What distinguishes an engineer? It is a word in common use, but few of us can agree upon a definition. We ride on the railroad train; everyone knows whom we mean when we speak about the engineer of the train, and yet in the present talk we do not consider this man as necessarily belonging to the engineering profession. Our lives depend largely upon his faithfulness to duty, his intelligence and his skill; no man ranks higher in public confidence than the locomotive engineers who are safely carrying each day millions of passengers. In our present discussion, however, we have in mind not the engineer who operates an engine, nor the mechanic however skilled he may be, but rather the man, who may be a mechanic or engine-runner, but who is essentially something more. What is that quality which we are endeavoring to include in the term 'engineer'?

The quality which distinguishes the engineer as a professional man from his brother the mechanic is education. The engineer is undoubtedly benefited if at the same time he is a good mechanic, although he may be a success even if he has little or no mechanical ability. To be an engineer in the true sense, he must have, however, that education which enables him to understand the true perspective of things, to know the big from the little, to obtain facts and judge correctly from these.

Why should he serve? The education of the engineer, whether obtained through books or through things, has been largely at the expense of some other person—either society, the state, or his more immediate employers. If he is a graduate of a university or an engineering school, the cost of his education, in part at least, has been borne by the philanthropically endowed college or by taxes levied directly or indirectly for the support of a state institution. If he is not a college graduate his early education has been more largely at the expense of his parents and to a less degree at that of his employer. It is assumed usually that in the case of an employer he has returned value received, but most of the older engineers will testify that they have usually made large investments in educating young and untrained men from whom they have not always received a full return. However this may be, it is safe to say that the majority of engineers are indebted to some one for the opportunities which they enjoy; as a body they owe a duty to the state and to society as well as to their profession.

It is this recognition of duty which gives rise to the ethics of the engineering profession and which distinguishes the engineer as a professional man from the ordinary mechanic, who from lack of this education does not feel bound to the same degree by written or unwritten codes. These ethics are well recognized, although like many other matters of common knowledge they are often difficult of exact definition. We know when they have been violated and yet may debate long as to the exact line between ethical and unethical conduct. The conception of engineering ethics is fundamental to the profession, and finds its highest expression in service.

Service to the public and to the engineering profession by means of service to the members should be the motto of any organization of engineers.

What is this service which all should be eager to render and which is the fruition of years of training? What do we mean when we claim that the highest function of the engineer and his greatest reward is found in effective service? The word conveys the idea of help rendered to another, not as a favor involving an obligation, nor on the other hand as a matter of self-sacrifice. It is something which may be expected though it cannot be demanded, and may be performed among equals. Service consists of those acts which tend to lessen trouble or increase the health, prosperity, and convenience of others.

Engineers in performing service are by this very fact entitled to full recognition. Service implies a suitable reward, and while the effort may be altruistic, it does not involve unnecessary self-denial. A proper remuneration, one assuring a good living, is due to the engineer. He who performs service rightfully does it with full expectation of reward, directly or indirectly in the satisfaction of duty well done.

*Abstract of an address before the American Association of Engineers, September 14, 1915.

Air-Froth Flotation

A LEGAL VERSION OF THE TECHNOLOGY OF THE PROCESS

[Herewith we give a part of the address made by Mr. Walter A. Scott, counsel for defendants in the case of Minerals Separation *v.* Miami recently tried at Wilmington, Delaware. We give this not only because the learned gentleman discusses the underlying principles of the flotation process in an interesting way but because the questions put by the Judge are such as would suggest themselves to other persons curious to understand the subject. In reading this excerpt from the court proceedings our readers must not forget that it is an *ex parte* statement, putting forth the technology of the subject with a view to aiding the case for the defendant. Mr. Scott assumes that oil is necessary to flotation and also that the force of surface tension bursts the bubbles. Neither of these assumptions can be taken for granted in a scientific discussion, however useful they may be in a lawyer's brief. The perforated-coil machine to which he refers is shown on page 587 of this issue.—EDITOR.]

The manifestation of the force of surface tension is a phenomenon that shows itself as a tendency of any liquid body—we may confine ourselves to a liquid—to assume that shape in which it has the least surface. It is a well-known fact that in the form of a sphere the ratio of surface to volume is at the minimum. Therefore we can say that surface tension is that force or property which tends to cause a body of liquid to assume the spherical form, in order to make its surrounding surface as small as possible.

We are familiar with manifestations of this force: when a drop of water falls upon a hot stove, we see it immediately come into the form of a little sphere. The explanation of that probably is that the stove, being hot, generates a little steam all around the particles, and that frees it from interference by other forces, so that it assumes the shape which surface tension tends to give it.

I think the ordinary shot-tower, where molten lead when poured or dropped assumes the spherical form of shot is probably another manifestation of surface tension. The lead, instead of dropping in a formless mass as it passes through the air, under the influence of the contractile force around its surface is drawn up into a spherical body.

Another illustration is the tendency which we observe when water is spilled, we will say, upon a smooth surface or table. Were it not for surface tension it would spread out in an infinitely thin layer; gravity would tend to pull it down flat. But surface tension causes it to assume the form of a little bulge of water on the table. The viscosity of the water probably also plays a part in that. It is difficult to disentangle all of these causes. But surface tension surely is one of the forces to enter into that effect.

Now, this surface tension exists not only at the free air-surface (for instance, the surface of the water in this glass) but it exists at every point where there is a change of medium, that is, where the water encounters another substance. Surface tension here is along the water surface, the air surface, but that surface tension exists clear around the inner surface of the glass and at the bottom of the glass; it has the same relation to the water around the glass and at the bottom of the glass as next the atmosphere above. So this surface tension exerts itself about the entire surface of a body of liquid, tending to draw it into a spherical form.

As we observe a bubble—for instance, a soap-bubble—the idea that we are apt to have is that the bubble bursts from an interior force; that is, that it explodes. We are accustomed to that thought in connection with any explosion or bursting. I apprehend from the testimony of these experts that a lessening of this contractile force, or the surface tension, tends to permanency of a froth; from that fact I apprehend that the force causing a bubble to burst is not an expansive force from the inside, but that it is due to surface tension, if the surface tension is strong enough. For instance, imagine a soap-bubble, we will say, three inches in diameter. It is surrounded by a very thin film of water contaminated or modified by soap. The amount of water in that film which surrounds the air inside of the bubble is, as we may well imagine, very small. The ordinary soap bubble bursting upon this piece of paper would hardly leave a visible sign of water. Now, as that bubble exists as a bubble the surface of that very small amount of water is very large. It is the entire outer surface of that bubble, and the entire inner surface, where the film comes in contact with the exterior air, and where it comes in contact on the inside with the enclosed air. Now, over that immense surface, for it is truly immense in consideration of the small amount of water, there is this contractile force, as if around the bubble there were stretched a sheet of rubber constantly drawing inward to make that bubble smaller, and the effort of that force of surface tension to reduce the area of the water forming the film of the bubble, simply pulls it in, bursts it, reduces it to a drop, which has the minimum of surface. So I apprehend that the reason the bubbles in these froths burst is on account of that shrinking inward, that tendency of surface tension to gather the water into the smallest possible compass.

The experts who have testified in this case say (and their views are in harmony with the literature on the subject) that any substance which tends to lower or lessen the surface tension of water tends to make the bubbles or the froth more persistent or permanent: and in view of what I have said, I think the reason why these modifying agents which lower the surface tension of

water also tend to make the froth more permanent is clear. In the case of pure water, having a surface tension which I think is—well, it is arbitrarily represented by some numeral—we can say 1. It makes no difference. Now, that force of surface tension in clear water is strong enough to burst these bubbles. It pulls in and bursts them. But if the water is modified by some agent, such as an oil in emulsion, or a soluble substance, such as phenol or cresol, that contractile drawing-in force is lessened, and therefore the bubble has greater longevity, can exist longer, because there is not this constant pulling in. So, while this surface tension manifests itself in various ways and has been utilized in various ways, so far as this bubble flotation or froth flotation is concerned, I think it is clear why a lowering of that surface tension tends to permit a bubble to exist longer. And all of the experts in this case are in perfect agreement that an insoluble oil mixed up, or emulsified, lowers the surface tension in precisely the same way that a dissolved substance does.

The phenomenon of the flotation of small particles upon the surface of water, as upon the surface of water in that glass, has been referred to as surface tension flotation or skin flotation. That is a matter of arbitrary nomenclature. The surface tension effect does not enter into that effect any more than it does in bubble flotation. This stretched membrane, as we picture it, surrounding a body of liquid and tending to draw it into a small compass, also has the property of supporting a small particle upon the upper surface of a body of water, but the name 'surface tension' should not properly be restricted to that kind of a flotation, because the surface tension phenomena enter into all flotations, and it is the lowering of that surface tension that leads to the formation of these froths which have more or less permanency.

* * * * * * * * * *

Besides these various prior art patents and publications that I have referred to, in which the lowering of surface tension is utilized for the purpose of giving permanency to a froth or a bubble, we have other patents, I believe owned by the complainants in this case, patents issued to scientific men, technical men, the officials connected with these companies, in which they also explain the use of both soluble and insoluble reagents for the purpose of contributing efficiency to a bubble or froth process.

Notable among those is patent 788,247, which is in evidence.

Patent 788,247 was granted to Cattermole, Sulman, and Picard. Sulman and Picard are two of the grantees of the patent in suit. Now, in this process—

The Court (interposing): What is the date of that patent?

Mr. Scott: The date of the grant was April 25, 1905; the date of the application was March 29, 1904. In their statement of invention in patent 788,247 they say:

"Our process has for its object the separation of minerals from silicious or earthy matters of ores by means of soaps or similar compounds and is dependent upon the superior physical attraction exhibited by minerals for fatty or resin acids, or for certain other aromatic derivates, such as phenols, cresols, etc., which form soluble salts or compounds with alkaline hydrates."

Then upon the first page of that same patent they state:

"The mineral particles now attached to or more or less coated or enclosed by films of fatty or resin acids and the like, are capable of being separated from the gangue or earthy particles by various methods, depending upon this altered physical condition. For example, the coated mineral particles may be removed by generating gaseous bubbles in the mixture, which preferentially attach themselves to the fatty or similar acid coated particles and raise them to the surface of the pulp, whence they may be removed by skimming or the like."

There is a clear statement of the use of soluble agents, the very soluble agents which are mentioned in the patents here in suit, with their use in connection with gases for raising them to the surface, and the only way in which a gas can function is as a bubble, and this effect of lowering the surface tension was there brought about by the same substances which are in use today.

In patent 793,808, which is the patent disclosing the perforated spiral coil that we have had so much discussion about, the patentees state:

"The present invention relates to the concentration of ores by separation of the metalliferous constituents and graphite, carbon, sulphur and the like, from the gangue, by means of oils, grease, tar, or any similar substance which has a preferential affinity for metalliferous matter over gangue."

The tar there mentioned is one of the substances in use today. Coal-tar is the principal source, I think, of phenol and cresol, and it is used in a crude state in flotation operations. I think it is one of the substances which the answers to the interrogatories say has been used by the Miami company. It is partially soluble and partially insoluble. It is a mixture. And then this patent, after naming these substances, oil, grease, insoluble substances, and then mentioning in the same breath tar, which is partially soluble and partially insoluble, the same as is the frothing agent used at Miami, after explaining the use of these substances goes on to say:

"According to one method of carrying out our invention suitably crushed ore is suspended in water. To this suspension a proportion of oil, grease, or tar (hereinafter referred to as 'oil') is added and duly mixed with the mass by any suitable means in quantity insufficient to raise the oiled mineral by virtue of the flotation power of the oil alone. A suitable gas is now generated in or introduced into the mixture, such as air, carbonic acid gas, sulphurated hydrogen, or the like."

Now here again we have a process in which a soluble agent is used. Tar is not completely soluble, but the complainant has taken the position, which I will accept for the purpose of argument at present, that if any constituent of a substance is soluble, then the substance is a soluble agent under the second and third patents in suit. Accepting, for the sake of argument, this construction of

these patents, we have here disclosed, down to the minutest detail, every operation that is performed at Miami. We have tar, a mixture of soluble and insoluble agents; we have the admixture of that substance with the pulp; we have the introduction of that substance into a vessel provided at the bottom with means for the admission of air; that means being this perforated spiral coil.

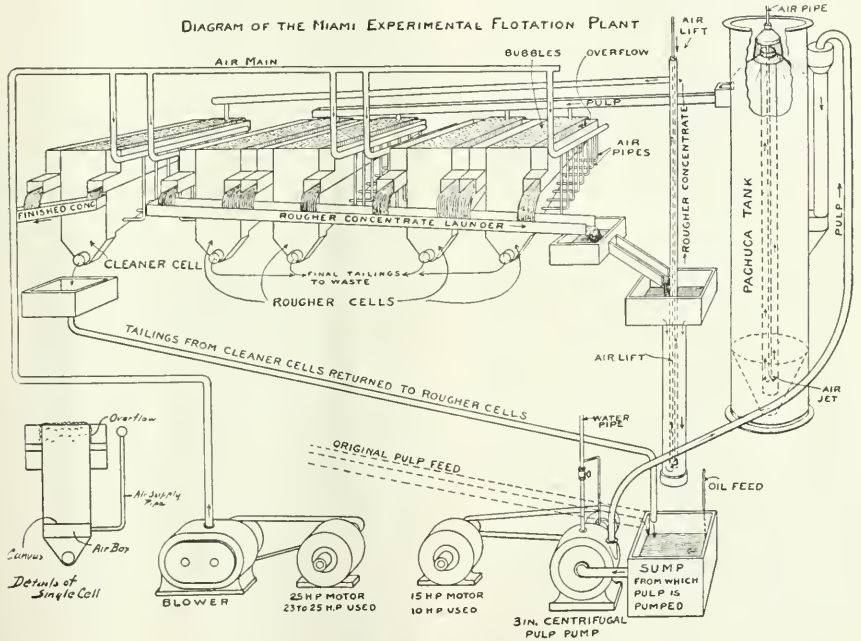
2 p.m. Same day.

Mr. Scott: If the Court please, just before the recess I was speaking of the spiral coil-pipe machine, the perforated spiral, and had stated that this process was identical with the operations at Miami. In fact, I think it will be difficult for anyone to conceive of any different action on the part of air bubbles escaping through fine holes in a metal pipe or a sheet of metal, and the same bubbles escaping through similar holes in a canvas bottom. I do not think the thing needs any argument, the two processes are absolutely identical.

An attempt has been made to establish the appearance of identity between that fragile mass of bubbles which results from the Miami operation, and from the patent 793,808 and the persistent froth that results from the violent agitation of the patents in suit.

Now certainly to the eye there is no identity whatever. And going further, looking to the real essence of the two operations, we find as great a distinction as there is in the appearance. The agitation froth results from violent agitation of the pulp, beating the air into very fine particles and then bringing the liquid to rest; as the Court has seen here in court, when the agitating mechanism was stopped, there arises this persistent froth which lasts for days. Even when shaken in a bottle in accordance with the directions of the California Technical Journal*, we showed the Court a froth that had stood for some two weeks, I think Mr. Dosenbach testified. That froth was so strong that it remained as a bridge across the bottle, even after the water had evaporated out from beneath it I think that matter was called to the attention of the Court, that the stopper had been left out, and that froth was so strong that it simply adhered to the sides of the bottle, and bridged across the bottle without any support whatever from below. That is characteristic of all these froths that are formed by this violent agitation.

Now contrasting with that we have what was exhibited



AN ILLUSTRATION USED IN THE BUTTE & SUPERIOR CASE.

to the Court in many experiments with the canvas-bottom machine, our Exhibit 53, and in the perforated spiral-pipe machine, our Exhibit 52.

The first difference that strikes one is that in this agitation process the liquid must be brought to rest before the froth will form. The froth will not form in the presence of and simultaneously with that violent agitation. The agitating mechanism either must be stopped, or the liquid must be conducted into a side vessel where it will be quiet. As it was exhibited in court, the agitating mechanism was stopped, that being merely for convenience in demonstration. Both complainant and defendant did it in that manner. Of course, that would

*[*The California Journal of Technology.* Mr. Scott is referring to the article by the three students abstracted in our issue of July 31, 1915.—Editor.]

make the operation intermittent if it was applied in practice. It would simply be agitated, and stop, and take off some froth, and then take more material, and agitate again. As I think the Court is informed, in practice the pulp flows in a continuous stream through these agitating vessels and then into quiet vessels where there is no agitator, vessels called 'spitzkasten,' and the current as it flows along is so slow and gentle that the froth rises in these quiet spitzkasten after having been previously agitated in the adjoining agitation vessel. And that is a *sine qua non* of this agitation process: that the pulp be subjected first to violent agitation and then be brought to rest for this coherent froth to rise.

Now, it is equally of the essence and vital to the process carried on at Miami that just the opposite conditions prevail. In the process as carried on at Miami the bubbles which carry the metal concentrate to the surface can rise and can exist only in the presence of these incoming streams of air from the bottom of the vessel. The complainant has contended that the mere gentle entrance of these bubbles at the bottom of the vessel is the equivalent of the violent agitation which forms a vital and essential element in the processes of the patents in suit.

There again to the eye there is no similarity and no equivalency. In the agitation-froth process of the patents in suit—and they are all alike in the mechanical treatment of the pulp by agitation—we have a mass of water that is beaten into a perfect vortex or maelstrom, as violent a movement as we can conceive of; whereas in the Miami process where the air is admitted through a permeable bottom, we have no more agitation than one would observe in a glass of charged liquor, soda water or champagne. There are simply the rising bubbles coming through the liquid. So far there is no similarity.

Look at the principle of the thing. There is an even greater dissimilarity. In the first place, as I have just stated, in the agitation-froth process the froth or bubbles can rise only after the agitation has stopped, or after the pulp has been conducted to a quiet place away from the agitating vessel.

In the Miami process the moment the influx of air stops—and air is what is contended to be the equivalent of the agitation, that is, the incoming stream of air—the minute that stops in the Miami process, the entire body of bubbles carrying the concentrate collapses, and I think your Honor has a vivid impression of that demonstration in which Mr. Yerxa and Mr. Hunt first turned on the air in that spiral-coil machine, and in the canvas-bottom machine, and built up this mass of bubbles, and then suddenly turned the air off, whereupon this all dropped.

Now, looking at the matter of equivalency, it seems to be an impossible construction of the facts and law to urge that the incoming air-streams in the bottom of the permeable-bottom cell, whether it be the spiral pipe or the canvas bottom, is the equivalent of the agitation, when their action is precisely opposite in respect to the formation of the froth. In one case the froth forms only when the agitation ceases. In the other the floating or rising bubbles exist only while the so-called agitation is going on. The principle of the two things is as different as the manifestation of that principle. The manifestation differs in this respect that I have pointed out. In one the froth rises when the agitation stops. In the other the bubbles can rise only when this so-called agitation is going on.

Now as to the principle. The two processes attack the problem in completely different ways. In the agitation-froth process the thought is so to treat this pulp by violent agitation that a froth will form and exist after agitation, that froth to be of so permanent and lasting a character that it can be manipulated, can be floated or skimmed off, as the Court has seen witnesses do in this case. The idea there, was by this agitation to effect a separation more or less permanent between the gangue and the concentrate, to get the gangue at the bottom and the concentrate at the top—to stratify them, as it were. We have the two strata with an intervening stratum of water. And then to take off that froth in any way which may be convenient, either by simply flowing off or by skimming, as has been explained by complainants' witnesses in that instance where they had a revolving paddle something after the fashion of the stern-wheel on some of the river-steamers. That paddle would revolve and scrape off this froth.

In the Miami process the mode of attack upon the problem is completely different. There is no idea in the Miami process of stratifying these materials and making a permanent float, which can be scraped off or floated off. The thought there, and the process as actually carried out, is to admit at the bottom of the vessel containing the pulp with the agent that is used, a stream of air bubbles which act, as Dr. Liebmann has said, simply like an updraft. These air bubbles, rising by the force of gravity through the water, collect the mineral particles by reason of the fact that they do collect them. That is about all that we can say, that the mineral particles adhere to these bubbles while the gangue does not.

Then the bubbles come to the surface of the water and break almost instantly. There is a constant succession of breaking bubbles, but the influx of air at the bottom of this vessel manufactures these bubbles at a slightly more rapid rate than they break, and for that reason the upper layer of bubbles is overflowed from the top of the vessel and saved, with their burden of mineral. The only reason that the Miami process is a success, or that the process of patent 793,808 is a success, is that it is possible by these rising bubbles to make the bubbles a little faster than they break. If they broke as fast as they were made, we would never have any appreciable amount of bubbles on top. They would simply break, each one in time for the next one to come up; but as it is there is a small interval of time before they break, and more bubbles are being formed at a rate so rapid that some of those bubbles are raised to the top and carried over the top before they have broken, and that is the only reason that it is possible to concentrate ores in that way.

The frothing process, on the other hand, is not depend-

ent upon any such principle at all. The thing is simply agitated violently, and when the agitation stops, this froth rises and floats much the same as a board would. It may not be as long-lived as a piece of wood, but it lasts for weeks, and it simply rises there and floats. Speaking with regard to the purpose of concentration, it is permanent, within the limitations that permaneney is necessary or desirable.

Now in view—

THE COURT: Let me see if I get your idea. Do you draw a distinction between a process which results in the formation of what is termed a permanent froth, and a process in which the bubbles come up in rapid succession, but not in such quantities or in such close proximity as to form a permanent froth, but as soon as they get to the surface they float away; is that what you mean?

MR. SCOTT: They float over, if we get them over before they break. It is a kind of a race.

THE COURT: If you get them over before they break? But suppose they break before you get them over, what becomes of the mineral?

MR. SCOTT: Then, as is shown in these demonstrations, if they do break, the mineral drops, and it is caught by the bubbles below.

THE COURT: And brought up again?

MR. SCOTT: And brought up again. The bubbles must be brought up fast enough so that it will gradually be raised.

THE COURT: That is, above the surface?

MR. SCOTT: Yes. There must be new bubbles coming fast enough so that it is gradually carried up over.

THE COURT: And they float off?

MR. SCOTT: And finally float off.

THE COURT: That is what I meant. I did not express it in that way. You expressed it in two stages, a first mass of bubbles and a succeeding mass of bubbles, but that was what was in my mind.

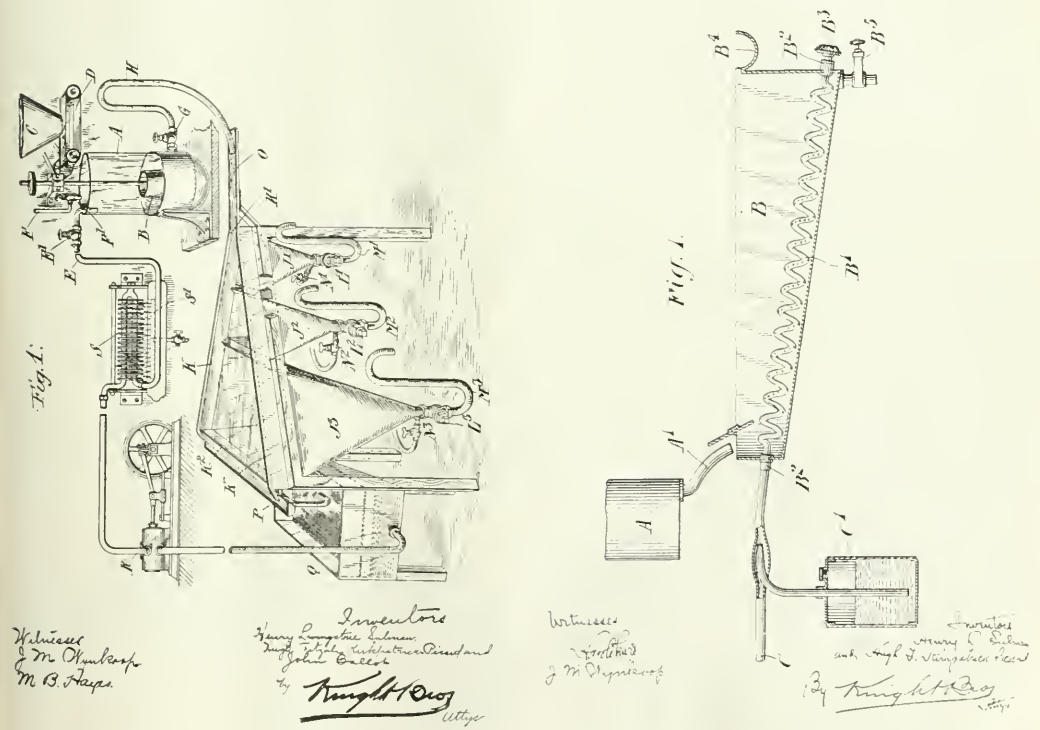
MR. SCOTT: The same idea, I think.

THE COURT: That there is no permanence?

MR. SCOTT: No permanence in the bubbles process at Miami. Now, if the Court remembers the mass of bubbles was probably about 6 inches high above the water, as I remember it.

MR. KENYON: Ten or twelve inches high.

MR. SCOTT: Ten or twelve inches high. It was quite high. Now, if a particle should be allowed to drop by



REDUCED FACSIMILES OF DRAWINGS ACCOMPANYING TWO IMPORTANT PATENTS.

reason of the bubble breaking, it would be caught on a bubble below, and thus constantly raised up by new bubbles coming into the bottom, so that it is, as you might say, a case of stepping back an inch and going forward two inches, and gradually getting over, despite the breaking of the bubbles.

The term 'flotation' seems inaccurate as applied to this Miami process. In the agitation-froth process, after the agitation is stopped, this froth actually does float. It will float for hours, and days, and weeks, and stay on the top of the water; but in the Miami process, as soon as the incoming current of air stops, everything drops, and we have the clear water-surface on the top of the cell. Now, that demonstrates absolutely that that mass of bubbles several inches deep, which we see in the Miami process operation, or that of the patent 793,808, is not really floating. It is held up there by the current of air, which holds it in place. That current of air not only manufactures these bubbles so fast that we have that mass of bubbles there, but it actually holds them up in position, and the minute the air is turned off everything drops. The mineral goes right to the bottom, and the bubbles break. So that instead of a floating mass of concentrate, it seems to me that it is best described, as I think I did once before in opening the case, by saying that this Miami operation is similar to these devices we have seen, where a stream of air is blown out of a pipe and a ball floats above it. The minute the stream of air is turned off the ball drops. In popular language, we may say that that ball is floating in the air, but obviously that is a misnomer, if we attach any exact meaning to our words.

Now, the Miami process is analogous to this ball held up on that stream of air. The agitation-froth process is the ball floating in the water. The two things operate upon absolutely different principles, and the difference is so great that it cannot escape anyone's notice.

Dr. Liebmann has characterized this Miami cell, or Callow cell, as he calls it, as an upcast, and the figure of speech is very happy. We took an ordinary upcast with water, such as that which was used for separating the Cattermole granules; and the Court will well remember that the mixture, the granules and gangue, was brought downward into a pipe, and water was flowing upward in the pipe, and that upward stream of water carried off the light tailing, and the heavy granules sank to the bottom. Now, 'upcast' is the term that is ordinarily used, and the action which takes place in this Miami process is absolutely analogous to that. It is not a floating operation. It is an operation in which, in a rising current of air, gravity is strong enough to pull some of the particles down, but the other particles are of such gravity and shape that the rising current of air carries them up against the force of gravity.

THE COURT: Let me ask you, where is the gangue separated from the metal?

MR. SCOTT: In the Miami process?

THE COURT: Yes.

MR. SCOTT: The gangue comes out at the bottom and the mineral is carried over the top.

THE COURT: Yes. How is that the result of this upcast?

MR. SCOTT: Of air?

THE COURT: What is it that separates the gangue from the particles?

MR. SCOTT: The rationale of the thing is evidently this: We have in this cell, or tank with the porous bottom, water carrying in suspension both gangue particles and mineral particles, and the mixture has been treated with some of these agents—tar, or coal tar, or what not—mixed up with it. In the first place, those air bubbles attract to themselves the mineral particles and do not attract the gangue particles; so that at that stage of the operation we have in the water a series of bubbles with the mineral particles sticking to them, and we have the gangue particles free in the water itself. Now, those bubbles rise, of course, by gravity and carry with them those mineral particles. The combination of the bubble and the mineral particle is together lighter than water, so it goes to the top.

THE COURT: I understand.

MR. SCOTT: And the gangue particle has had no assistance whatever from the air. It is still heavier than water, the way it always was, and it goes to the bottom.

THE COURT: I understand, then, that in the Miami process the bubble attaches itself to the mineral below the surface.

MR. SCOTT: Below the surface, yes.

THE COURT: And carries the mineral—

MR. SCOTT: Up to the top.

THE COURT: Up to the surface, or above the surface?

MR. SCOTT: Precisely.

THE COURT: Now, where in the complainant's process does the bubble attach itself to the mineral—below the surface or above?

MR. SCOTT: I think that must be below the surface, too.

THE COURT: And it carries it up, does it?

MR. SCOTT: It carries it up to the top.

THE COURTS Now, you may assume that I do not know froth, rather than of concentration—the difference between the two processes? I understand that the purpose of the patent is to effect not a froth, but a concentration.

MR. SCOTT: Precisely.

THE COURT: A separation?

MR. SCOTT: Precisely.

THE COURT: Now, you may assume that I do not know anything about this. I want to have it put to me as plainly as you can express yourself. What is the distinction in principle between those two processes? You have explained the difference in point of actual operation. Now, what is the distinction in principle, when it comes to the formulation of any principle, between these two operations, as bearing upon the question of the separation and saving of the metal particles?

MR. SCOTT: The broad principles are the same in both. In both we have the pulp, consisting of ore held in suspension in water. In both the water is modified

to lower its surface tension. In both the buoyancy comes from air bubbles. The difference comes after the air bubbles have attached themselves to the mineral particles. In the agitation-froth process the air is beaten into very minute bubbles, and when they rise with these mineral particles they form this permanent froth. The permanent froth is then floated off or skimmed off. Now, in the Miami process there is no beating up of the liquid, of the pulp. The bubbles are larger and more fragile, and instead of forming a permanent froth, which will float, the thing is simply pushed off by the current of air. The basic principles are the same in both of them. The method practised at Miami is the older of the methods. It is the method of the patent 793,808, with the perforated spiral coil.

Now, speaking so far as patents go, departing from the Court's question as to the general principle of the thing, which is identical up to the point I have explained—departing from broad explanations and approaching it from the patent side purely, the patents in suit must necessarily, if they have any validity whatever, be restricted to this permanent froth formed by this mechanical agitation, or they must confessedly be invalid by the prior existence of the perforated coil-pipe machine.

THE COURT: Let me ask you another question.

MR. SCOTT: Certainly, I am very glad to have you do so.

THE COURT: When was the perforated-coil machine first used?

MR. SCOTT: As far as the record in this case shows—

THE COURT: I mean with respect to the first patent in suit.

MR. SCOTT: The date of the application was about a couple of years before, and I think the patent was granted about a month before the application in this country. I will give you the exact dates.†

THE COURT: I mean, was it before?

MR. SCOTT: Oh, absolutely.

THE COURT: Before the first patent in suit?

MR. SCOTT: Before the first patent in suit.

THE COURT: Now, let me ask you, what were the ingredients that were used, and what proportions were used?

MR. SCOTT: In this patent the ingredients—and, of course, in all of these—are the ore-pulp in the first place: the water and the ore.

THE COURT: Yes.

MR. SCOTT: And the ingredients for effecting bubble formation in this patent 793,808 are oils, grease and tar, or any similar substance, which has a preferential affinity for metalliferous matter over gangue.

THE COURT: And in what proportions?

MR. SCOTT: The proportions are stated in the patent in this language—there are no figures—in line 89 of the first page of that patent:

"We have also found that a particle of metalliferous mineral, if coated with a minute film of oil, grease or the like* * * * "

And so forth. That expression, "minute film" certainly gives us indication of a very small quantity, because the word 'film,' without any qualification whatever, conveys to the mind the idea of a very small amount; and when you say "a minute film" we are getting about the strongest expression of the necessity of a small quantity that words can convey.

There is one other place in this patent where I think the quantity is similarly characterized.

MR. SHERIDAN: At the top of page 2.

MR. SCOTT: "A small proportion of oil," following the "minute film."

This brings us, of course, to what I regard as the only real question in the case, and that is as to whether there is any distinction in principle between the froth which is formed with a very small quantity of oil and one which is formed with a larger quantity; in other words, whether there is a difference between an air-froth and an oil-froth.

†[The coil-pipe patent (No. 793,808) is dated July 4, 1905, but the application was filed on October 5, 1903. On the other hand the basic agitation-froth patent No. 835,120 is dated November 6, 1906, while application for it was made on May 29, 1905.—EDITOR.]

EXPLOSIVES. The use of liquid oxygen in explosives promises to be considerably developed in the future. In the early experiments of Linde, the liquid containing 50% of oxygen, which was obtained from his original apparatus, was poured onto fragments of wood charcoal, from 2 to 4 millimetres in size. The fragments were kept from scattering, as the liquid boiled, by making them into a sponge with one-third their weight of cotton-wool. In more recent experiments, at the cutting of the Simplon Tunnel, a mixture in equal proportions of carbon and petroleum, which took up eight parts of liquid oxygen, was used with some success, and lately excellent results have been obtained by Messrs. Claude and D'Arsonval working in collaboration for the French government. The chief object of their investigations was to produce an explosive which gave rise to no injurious gases. For this purpose a mixture of powdered aluminum, with an excess of liquid oxygen, was tried, with a very encouraging success, and the explosive was found to be equal to twice its weight of gunpowder. Further experiments by the same investigators with carbon-oxygen explosives show that these have the same power as dynamite, and, as the cost of each of the constituents is less than two cents per pound, it is predicted that the new explosive will, as soon as further experiments are completed, be widely used. The principal difficulty in the way of its adoption is the transportation of the liquid oxygen, but this should shortly be overcome. —*Engineering*, London.

THE EXISTENCE of gold in the Klondike was known to the officials of the Hudson's Bay Company as early as 1850, but their fear that the miners would frighten away the fur-bearing animals caused them to forbid their employees to divulge the mineral wealth of the country.

How My First Introduction to Flotation Bubbles Cost Me Hard Labor and More Bubbles

By BEN. S. REVETT

As a preface to my first introduction to the separation of minerals by flotation, I think it may not be amiss to relate an incident that has led me at various times to investigate propositions outside my own branch of engineering.

In the early seventies in my collegiate days, I belonged to a volunteer corps, and at the time of the Wimbledon meeting, when all the rifle-shots of the British Isles and Colonies gathered for their annual sharp-shooters' meeting, I was returning home dressed in my regimentals, the only other passenger in the first-class compartment of the London & South Western railway being an apparently well-to-do farmer, his only package a wicker hamper about the size of a modern automobile lunch-basket. My curiosity was aroused by hearing something moving inside, whereupon I asked, "Pardon me, Sir, but are those puppies you have in your hamper?" "No, pigeons." "May I ask what you do traveling around the country with pigeons?" "Fly 'em." (As I could not disassociate my traveling companion from doing anything except for commercial reasons.) "Pardon me, I trust you will not think me rude, but is there any money in flying pigeons?" "Naw, it's a 'obby; volunteering, young man is your 'obby or you would not be wearing that uniform. You are not doing it for money—flying pigeons is my 'obby, and there is no money in it, and I am not doing it for money but just because it is a 'obby. Young man, let me tell you that any man without a 'obby is a Hass."

This episode I have never forgotten. In consequence I have at times profited and at other times lost both time and money in following up someone's hobby, but I have always thought it well worth while to investigate anything new to which another man had devoted time and serious study, particularly in these days of specialties.

As a result, in the winter of 1889 and '90, while spending several months in California, Idaho, and Oregon, in the pursuit of my own hobby, alluvial mining, I drove out one day to Sparta, a small mining settlement about 40 miles north of Baker City, Oregon, to investigate some placers. Going into the general store, the only pretentious building in the town, I was amazed to find a man of most generous proportions, who tipped the beam at over 300 pounds, clad in a Prince Albert coat and silk hat, discoursing to a motley gathering of stove-pipe miners and others. At first I thought it was some patent-medicine vendor, but on listening I learned that he was telling them of a patent process for the separation and concentration of minerals by grease flotation. Upon walking up, the stout gentleman introduced himself as Mr. Criley, part owner and associate patentee of the Criley & Everson Oil Flotation & Concentration Process, of which he had just completed making a simple demonstration. I said: "Why, Mr. Criley, you are making a decided jump against all known metallurgical practice, as at present grease of all kind is avoided in amalgamation, and mill-men avoid making slime." "True," he said, "that is what Mr. N. P. Hill, the smelter-man of Denver, told me, when he laughed at me, as I suppose you are going to do." I said, "No, Sir, I am not going to laugh at you because seemingly you have a hobby, for I have learned that it is interesting to listen to any man who has devoted time and serious thought to any particular subject, and therefore I should be glad to listen to you." He said, "Well, at least you will admit that unless something new was discovered from time to time the world would stagnate and everything come to a standstill." I said, "On that, Sir, we are agreed." Whereupon Mr. Criley told me of the discovery of Mrs. Everson, his associate, of the flotation of minerals by the reduction of specific gravity when enveloped with grease or oily substance, that he was a mechanic and millwright, and that he and Mrs. Everson were partners in the company, that he had a small model, which he took with him for exhibition purposes, and that he had his plant practically complete with the exception of a cheap filter to re-use his acid and oil after the minerals had been extracted therefrom.

Mr. Criley made me the proposition that if I would take a fair sample of the vein in a near-by mine, and would take it to an assay-office in Baker City, reduce the ore to 60-mesh, have the assayer make an assay of it, that he would bet me a quart of champagne that he could save all the minerals with grease and acid in accordance with the assay, and that he would also bet me another quart of "bubbles" that his tailing would not show a trace of mineral by assay. I took both bets and agreed to carry out the program. The following morning I got up bright and early and went to Mr. Blank's assay-office and asked him if he would lend me a bucking-board as I wished to pulp some ore. He informed me that he had no bucking-board but had a good hammer, anvil, pestle, and mortar, to all of which I was most welcome. I took off my coat at once, rolled up my sleeves, and proceeded with my physical task of reducing some pretty hard rock to pass through a 60-mesh screen. After I had been pounding away strenuously for about one and a half hours, Mr. Assayer appeared standing in the door-way, asking me what in the name of thunder I thought I was trying to do. Whereupon I told him of Mr.

Criley's proposition and our bets. He laughed and said, "You are not chump enough to waste your time on any such fool proposition as that, are you." I replied that I was, and told him of the story of my friend and the pigeons, and that a man without a hobby was a "Hass," that I had found a man with a hobby and wanted to determine which was the ass, he or myself. Another hour passed laboriously along, when Mr. Assayer again came to the door: "Say, I have been thinking this proposition over, and there might be something to the fool thing after all. I will make the assays for you and they won't cost you a cent." "All right, Sir, thank you," said I. "You are Umpire and referee, you shall decide, and also participate in the bubbles whether I win or lose." About 4 o'clock the stage drove up to the door of the assay-office and portly Mr. Criley rolled off the box. Mr. Blank, the assayer, having quartered down the pulp, taken his samples and made his assays, Mr. Criley hung his Prince Albert, silk hat, and cuffs on the wall and proceeded to get ready for business by asking for a wash-bowl, hot water, some sulphuric acid, and some grease, all of which were cheerfully furnished by Mr. Blank, the assayer, who, by this time, was as much interested in the bubbles—of course I mean the flotation bubbles—and the experiment as I was myself. Mr. Criley filled an earthen bowl with hot water and enough sulphuric acid so that the acidity was just susceptible to the taste, thoroughly impregnating his pulp with some old signal-oil; he kept stirring and stirring until the bubbles floated to the surface of the water and acid, whereupon he panned them off into a handkerchief that he used for a filter, getting his mineral product on the top of the water and not on the bottom of the water as in the usual method of gold-panning. Stirring and agitating until he could not float any more bubbles, he squeezed his handkerchief containing the product, washed off his tailing, handed them to the assayer for check-assays, with the result that I lost two quarts of "bubbles."

Mr. Criley left next day for Portland, and at the depôt, searching for some baggage of mine that had been lost, he got into conversation with the owner of a fish-oil refinery, from whom he learned about a filter, an English invention the patent on which had expired. This, in his opinion, was the one thing lacking to make the Criley-Everson process a commercial success.

As a result of listening to a man's hobby, I saw practically one of the first demonstrations of the Criley-Everson flotation process, which is now conceded to have been the pioneer of oil-flotation methods of concentration.

TRIBOPHOSPHORESCENCE, or phosphoresence by friction, is shown by ore from Mariposa county, which exhibits a train of light when scratched by a nail. This striking phosphorescence has led some persons to think the ore contained radium and a patent-medicine company is said to use this phenomenon to advertise a nostrum. The mineral in this Mariposa ore is sphalerite, or zinc-blende. This phenomenon is also shown by sphalerite from Utah, which gives off a yellow light when rubbed with the finger or a match. When a steel brush is pressed against the powdered mineral glued on a cardboard disc that is made to rotate 12 r.p.s., the light is visible at a distance of several yards. Chlorophane shows a bright-green color that lasts 0.40 second; this is best obtained by friction of a specimen against a grindstone or corundum wheel. Dr. George F. Kunz finds a zinc-blende from Utah the most luminescent substance known. Two fragments one fourth the size of a pea, if pressed together lightly with the fingers, caused a brilliant yellow-green light to flow as long as the pressure lasted. This zinc-blende was radioactive to the *beta* and *gamma* rays of radium; it was the first natural blende examined that possessed this remarkable property. Quartz, corundum, pectolite, limestone, and willemite possess tribophosphorescence, but to a less degree than either chlorophane or zinc-blende.

CLEVER SALTING. The engineer who is engaged in mine examination should distrust every person who has any chance of tampering with the deposit he is examining or with the ore samples that he takes. This rule should be especially observed by the engineer when in strange lands. An interesting case of 'salting'—the victim was an English engineer—took place in Brazil a few years ago. The engineer had examined a gold placer and found it not quite rich enough for his clients, but noticing the rough edges of the nuggets, and the presence of some crystalline gold, he came to the conclusion that the gold had not traveled far. On communicating his theory to the natives they assisted him in prospecting for the 'mother lode' and his researches led him to a ridge of soft shale at the head of the little valley in which the placer was situated. No quartz could be found, and thinking that the quartz-vein might be covered by surface soil, a trench was run at right angles to the strike of the slate; careful panning of every foot as the trench advanced showed nothing of value for the first 10 ft. and then a small amount of gold for a width of a few feet. Cheered by this verification of his theory, though somewhat disappointed by the small quantity of gold found, another trench was started parallel to the first and higher up the ridge; here the ore-belt was found to be wider and richer and finally a whole series of trenches developed an ore-zone half a mile long and with a maximum width of a hundred feet. The application of the transit, slide-rule, and trigonometrical tables proved a valuable orebody; the property was bought for a good price and preparations made for working the mine on a large scale, but on starting actual work it was found that the only gold in the trenches was the 'salt' put there by the amiable owners of the property. The net result was a loss of reputation by the engineer and some $200,000 by his clients.

The Brazilian native is an ingratiating creature; so humble in his self-depreciation; so overpowered by the vast knowledge and technical skill of the modern scientific engineer from Europe or America that it is hard for the visitor to realize that the native is in reality a master-miner and that when he has finished with a placer claim there are no profits left for a stock company.

Coarse-Crushing Plant of 1000 Tons Capacity

By G. O. BRADLEY*

†In recent years the equipment and arrangement of crushing plants are receiving the same careful study and attention on the part of mill-men and engineers that is devoted to the other departments of modern reduction works. This general awakening of interest is evident from the fact that we now have in operation many efficient crushing installations that compare most favorably with the other departments as regards economical performance. We have passed beyond the age of grossly light and inefficient apparatus for this important work, and one can plainly see the results reflected in the cost-sheets of our up-to-date plants.

We now have on the market various types of crushing machinery, which have been developed and perfected after years of experience. For this we are indebted in a marked degree to the manufacturers, as they have willingly supported us with their own engineering skill, as well as liberality, in the replacing of machine-parts that may have proved inefficient or not suited to the service required. Today, the engineer has at his command a most complete line of primary-crushing and coarse-grinding machinery. In my opinion, the following classification may safely be followed in making the proper selection of a primary crusher that will give the best results on a given ore:

Character of ore.	Type of crusher recommended.
1. A hard, tough, sharp-breaking rock	(a) Gyratory crusher
	(b) Jaw-crusher
	(c) Edison rolls crusher
2. Medium-breaking ore	(a) Gyratory crusher
	(b) Jaw-crusher
	(c) Fairmount crusher
	(d) Edison rolls
3. Soft, easy-breaking, clayey ore	(a) Fairmount crusher
	(b) Edison rolls.

The Fairmount crusher is a new development in primary crushing machinery; its design is along the lines of a compromise between the Edison rolls and the jaw-crusher, in that it has a single segmental jaw and a single revolving hub or core, into which are inserted manganese-steel breaking-lugs or knobules. The jaw is held up to the work by means of massive tension-rods.

It resolves itself, therefore, upon the engineer to select the apparatus best adapted to the particular problem that he is to deal with. It is, of course, important that he should have in his possession all the data relative to the plant requirements and the character of ore to be treated, and in this connection I have outlined the principal subjects of information for the general guidance of the designer, as follows:

1. The system of mining employed. This can be divided into two classes: surface and underground work respectively.

2. The capacity of plant per hour in tons, and the uniformity of the finished product.

3. Nature of the material to be crushed, degree of hardness, and moisture characteristics.

4. The proper placing of the plant in its relation to the other departments.

5. Mechanical efficiency, accessibility to all working-parts of the machinery, and the economy of operation.

6. The type of power available.

7. Class and type of construction.

8. Lighting, heating, and ventilation.

Surface mining requires, as a rule, massive equipment for primary crushing, for the reason that it is necessary to rough down the large pieces of rock too cumbersome to be handled economically within the limits of a finishing plant: therefore, in the case of steam-shovels or surface mining, the gyratory crushers shown should be preceded with a primary crushing or roughing plant.

The arrangement of the plant selected to accompany this discussion is illustrated by the accompanying drawings, Plates I, II, III, and IV. The design is offered with a view to answering the general requirements of coarse crushing as applied to any system of underground mining where it is desired to produce a finished product for subsequent milling operations. In the selection of the design, I have been governed by the following general conditions.

Flow-Sheet: The primary ore to be delivered to the crushing plant at the receiving point above the grizzly-screens, or it can conveniently be delivered directly into the coarse-ore bin, as shown on Plate III under the notation, "Alternative delivery point for the coarse ore."

The ore is fed from the bin into the gyratory crushers, which, after crushing, discharge into the receiving-pockets, from which it is elevated by means of the automatic skips and discharged over the grizzly.

The oversize returns to the coarse-bin by gravity for re-crushing, and is retained in this closed circuit until it is fine enough to pass the grizzly. The undersize is fed onto a conveyor by revolving drum-type feeders and is conveyed to the fine-ore bin, more plainly shown on Plates I and II.

From this point, the ore is fed uniformly over the dry impact-screens, and the oversize is collected on the

*Consulting Engineer, San Francisco.

†A paper presented before the International Engineering Congress, San Francisco, September, 1915.

lateral conveyors, which discharge into the 54 by 20-in. rolls.

The undersize from the impact-screens is discharged onto the conveyor for the finished product, as indicated more clearly on Plate II.

The ore, after passing the rolls, falls by gravity into the receiving-pockets, and is charged automatically into the skips and returned to the fine-ore bin, where the above process is repeated until the ore is reduced sufficiently to pass the ¼-in. mesh screens.

Type of Plant: Dry crushing.

Capacity: 1000 tons per day.

Material: Ore of average hardness, and such as produced by the present practice of underground mining.

Equipment: Arranged for graded crushing and rolling, with oversize return.

Product: Finishing to pass through ¼-in. mesh screen.

Power: Electricity.

Construction: Concrete and steel throughout.

A general description of the equipment to be in accordance with the following discussion under their respective sub-headings:

Building: The building to be of concrete and steel construction throughout, having the coarse and fine-ore bins in alignment at the head of the mill, and arranged for electric crane-way over the entire operating-floor. All crushing machinery and auxiliary apparatus to be installed on a single level, so as to minimize attendance and facilitate maintenance and repairs. The fine-ore bin to be constructed with the suspended-type steel bottom, which is more clearly illustrated on Plate II.

Crushers: The crushers contemplated for this installation are two No. 7 gyratory type, standard discharge, set to crush 2½-in. ring gauge.

Feeders: Each crusher is fed by an individual drum-type revolving feeder, placed at the side of the coarse-ore bin. The feeders are provided with proper housing and hand-operated geared cut-off gates between same and the ore-supply. The feeders are driven from the crusher pinion-shaft, thus insuring, automatically, a stoppage of feed when any one of the crushing units is not in operation.

Rolls: The 54-in. diameter by 20-in. face rolls proposed for this installation are of the heavy-pattern self-contained type. In each case the stationary rigid-roll shaft is provided with outboard bearing. The driving-pulleys are both mounted on the same side, in order to give a much greater factor of safety and freer access to the operator when making repairs or inspection of the running machines. The rolls are designed for a combined working load or spring capacity of 15,000-lb. pressure per inch of width on the roll-face. The main driving-pulley for each set of rolls is of the heavy fly-wheel type, 108-in. finished diameter by 17-in. crown face. The hubs and rims are of cast-steel, and the centre is formed by two steel-web plates ½-in. thick dished so as to give lateral stiffness. These plates are riveted to the hub and rim castings by machine-turned through-rivets. The approximate weight of each pulley is eight tons. This heavy fly-wheel has the effect of producing a steady and smooth-running unit, and increases the efficiency materially.

Feeders: The undersize ore is fed from the fine-ore bins by revolving or drum-type feeders, illustrated in section on Plates I and II and in plan on Section BB, Plate I. The ore is fed uniformly over the impact-screens, where the oversize is collected onto the belt-conveyor feeder, which carries same to the roll units. The undersize or finished product is collected by the branch launders and delivered onto the conveyor, where it is transported to the sampling and fine-grinding departments for further treatment.

Drives: The conveyors, feeders, and screen drives are taken from the roll shaft, as it will be noted that each set of rolls is provided with an independent nest of feeders and screens. The main drives consist of two 150-hp. motors of the double-end type, having a flexible coupling connecting the transmission shafts at each end, also a friction coupling or cut-off which enables the operator to run any machine independent or together as may be desired. This system of drives applies to both the crushers and rolls, as is clearly shown in Plates I, II, and III.

Automatic Skips: The crusher and roll units are each provided with balanced automatic skips in place of the belt-elevators commonly used for this class of work. The advantages of the skip over the belt-elevator are numerous. The skips are more wieldy and can operate to any height desired, making it possible to concentrate the equipment and operating labor, at the same time avoiding all the annoying evils so prevalent in connection with belt-elevators.

The operation of the balanced automatic skips will be in accordance with the following general description:

The arrangement of the loading apparatus at the bottom of the shaft is such that when the empty skip comes into place it engages the automatic-skip loading-mechanism, which closes gate *U* completely; then gate *R* starts to open. The measuring-hopper holds, when filled, one skip-load. As the weight of the load increases, the loaded skip compresses the weighted platform at the bottom of the shaft, overcoming the resistance of counter-weight *T*. This movement is sufficient to trip the lever operating a master controller, which automatically starts the hoist. As skip *B* starts to ascend, the engaging mechanism follows with it, due to the over-balancing of counter-weight *S*. The first cycle closes gate *R* completely, and as the skip continues on its upward movement gate *U* opens and remains in this position until the skip returns on its downward travel.

A geared limit-switch of the traveling-nut type is mounted on the hoist and so arranged as to allow the hoist to coast momentarily when either of the skips approaches the dumping position. Just before the skip

reaches its proper limit of travel, the limit-switch will automatically de-energize the solenoid brake, thus bringing the hoist to rest. Hatchway-limit switches are also placed in such a manner as to be operated by the motion of the skip itself. These hatchway-limit switches will serve as an additional precaution in case of failure of operations of the geared-limit switch. The master controller is also inter-connected by means of a double-throw knife switch, so that hand operation may be obtained at the will of the operator. The automatic master controller will have only three points, namely, a neutral position at the centre of throw and a position on each side of the centre for either direction of hoisting.

ESTIMATED COST

Building:		
Grading	$ 2,000	
Concrete	6,000	
Steel, building	31,500	
Steel, corrugated	2,085	
Sheathing and nailing strips	900	
Doors and windows	1,600	
Floors	360	
Grizzlies	385	
Stairs	750	
Lighting and wiring	2,300	
Launders	300	
Crane	4,000	
Painting	800	$ 52,980
Equipment:		
2 No. 8 crushers	8,100	
Freight, at $1.50 per 100 lb.	3,045	
Erection, at $1.50 per 100 lb.	3,045	
2 Gates and special chutes	90	
4 feeders	500	
12 feeders	1,500	
12 impact screens	2,760	
2 54 by 20-in. rolls	10,650	
Freight at $1.50 per 100 lb.	3,803	
Erection	2,500	
2 automatic hoists, complete	13,800	
4 loaders	1,680	
2 150-hp. motors and starters	3,900	
Complete transmission, belting, etc.	2,900	
Complete conveyors and drives	1,050	59,323
		$112,303
Miscellaneous and supervision, 5%		5,615
Total estimated cost		$117,918

The method of the operation and control will be as follows:

Assume that skip *A* is being hoisted and skip *B* being lowered. Just before the skip *A* reaches the dumping point, the hoist will be slowed down by gravity to approximately half-speed. When skip *A* has reached a point perhaps two feet from its final position, skip *B* will engage with the scale platform, depressing the latter for a short distance and increasing the load upon the motor by increasing the unbalanced effect of the upper skip. When skip *A* reaches its final limit of travel, the solenoid brake will be applied by means of the limit-switch. Skip *B*, however, will have to come to a standstill in the meantime, so that there will be a small amount of slack in the *B* cable. The ore now being dumped into skip *B* will cause a further depression of the platform and a movement of one of the operating arms attached to the automatic master. The latter, which has been in the proper position for hoisting skip *A*, will have its handle pushed past the neutral position and into the position for hoisting skip *B*; it will be held in place by a roller falling into a notch on a star wheel. Since the limit switch will offer no opposition to hoisting skip *B*, the latter will now start to rise. Retardation will then take place when skip *B* reaches the upper end of its travel, as previously described in the case of skip *A*.

Ferrous and Ferric Iron in Cyaniding

By WILL H. COGHILL*

What would cause a tailing that seems perfectly amenable to cyanide when taken direct from the pile, to show a prohibitive consumption of cyanide after being dried and crushed on the bucking board? The presence of ferric sulphate.

The tailing contained soluble iron salts. Before recrushing it contained 0.045 and 0.172% soluble ferrous and ferric iron, respectively. In laboratory parlance, it was dry when put through the disc pulverizer. After once through: soluble ferrous iron 0.18%; five times through, 0.203%; fifteen times through, 0.213%.

The above determinations were made after a three-minute water wash. It is possible that metallic iron from the crusher reduced some of the ferric iron during the wash, but a lime-water wash followed by cyaniding showed an increased cyanide consumption of about the same degree.

One would expect dissolved ferric sulphate to be reduced by metallic iron, but it must be remembered that 'dry' is only a relative term, and if the ore contains soluble ferric sulphate one must use the porcelain jar with flint pebbles for grinding unless the acidity be first neutralized.

Had crushing been undertaken at first instead of testing direct from the dump, the ore would have been condemned as refractory, but fortunately the laboratory and not the ore was found to be at fault.

The books do not warn the experimenter against this snare. In short, no matter how dry your ore is, if it contains ferric sulphate the work done upon it in an iron grinder or on the bucking-board is likely to cause a reaction between ore and apparatus, developing a disastrous cyanicide.

DIAMOND-DRILLING at the Le Roi No. 2. Co.'s Josie mine at Rossland, British Columbia, cost $1.64 per foot during its past fiscal year, when 12,249 ft. was driven. Labor accounted for 72c.; carbon, 60c.; and sundries, 32c. Two shifts required one diamond-setter, four miners, and four helpers.

COSTS at the Goldfield Consolidated in August were $4.86 per ton; mining was $2.56; and treatment, $1.71 per ton.

*Ore-testing laboratory, El Paso, Texas.

Non-Metallic Products

Compiled by S. H. DOLBEAR

Dolomite Uses and Production

But little attention has been attracted by the dolomite industry in California, although the amount consumed has increased considerably during the past few years.

Dolomite is a carbonate of lime and magnesia containing, when pure, 60% calcium carbonate and 40% magnesium carbonate. Impurities usually exist in the form of silica and silicates, and not infrequently metallic oxides or sulphides. Much of the California mineral contains perceptible amounts of iron pyrite.

The Columbia Marble Co. mines large quantities of dolomite from its quarries in Tuolumne county. This is shipped to the company's plant at San Francisco, where it is sawed into shapes and used for structural purposes. The spawls or scrap resulting from this operation, amounting to several hundred tons per year, are sold for industrial uses. Aside from this source, large amounts have been mined in the vicinity of Hollister in San Benito county, the latter output having been taken largely by local steel plants.

In addition to that used for structural purposes and in the steel mills, dolomite is crushed and closely sized by screening, and employed in artificial marble-work, terrazzo floors, and to some extent in the manufacture of roofing. The smaller sizes are sacked and sold for chicken grits.

Inyo County Pumice

Large deposits of pumice and pumiceous rock are found eight miles northeast of Little Lake, a station on the Aqueduct branch of the Southern Pacific railroad in Inyo county, California. This region is characteristically volcanic. A narrow bed of lava extends toward Indian Wells valley parallel with the Sierra Nevada a few miles west. At Coso Springs, three miles distant, is a solfatara. Sulphur, alkaline substances, silica, and metallic sulphides are being constantly brought to the surface by hot solutions, the metallic sulphides containing traces of both gold and silver.

The pumice deposits were taken up several years ago by San Francisco people, who mined several hundred tons. The claims lapsed and are now controlled by the C. W. Hill Chemical Co., of Los Angeles. This concern has made some shipments to Los Angeles, where the material is ground and prepared for market in the company's mill.

Much of the pumice found here is friable and may be reduced to a coarse sand by rubbing between the fingers. Fragments of more solid pumice are found, selected pieces of which have been pronounced by experts to be equal in quality to that of the Lipari islands, from which place most of the pumice of commerce is now obtained.

The occurrence of pumice in California is by no means limited to Inyo county. It is found in large quantities in Mono county, Shasta county, and in the vicinity of Salton Sea.

Industrial Applications of Quartz

The development of the non-metalliferous quartz business in the western part of the United States commenced with the advent of smelters, its first demand being for use with heavy sulphide ores having low silicious content. There is still some demand in this direction, although the development of the mining industry has made it possible for most smelters to secure silicious ores with sufficient metal content to pay expenses.

The second step in the development of this business was the attempt of glass manufacturers at San Francisco and Los Angeles to grind quartz as a substitute for Belgian and other sand. Neither attempt was successful, the expense of crushing being so great that the resultant product could not compete with the imported sand.

At Los Angeles, the Southwest Glass Co., which later became known as the Quartz Glass & Mfg. Co., while obliged to discontinue the attempt to manufacture bottles from quartz, found that a market could be developed in various industries for quartz crushed to various degrees of fineness. Crushed to the size of gravel and coarse sand it is used in the manufacture of artificial stone, in filters, in plastering the exterior of buildings, as chicken grits, etc. Carefully graded, it is used in the manufacture of sand-paper, sand-belts, and in the sand-blast. It is referred to as 'banding silica' when painted upon wood surfaces; the resultant coat being supposed to resist wear better than a smooth surface. Finely ground quartz, when water-floated, is used in the preparation of certain paints and as a wood-filler. Ground crystalline quartz is preferred for this purpose rather than ground silica sand, for the crystalline material is angular and adheres to the surface better. It is used to some extent in the preparation of ready roofing, a product rather coarser than ordinary sand being required for this purpose. It would be used for sawing marble if it could be produced cheaply. When finely ground, dry, in either a mill of the Fuller-Lehigh type, or in a pebble-mill, it is used in the manufacture of abrasive or scouring soaps. In steel-casting foundries it is washed on the surface of molds to fill voids in the mold surface. Potteries and manufacturers of sanitary ware are among the most important users of quartz, its function being to reduce shrinkage in the body of the ware. For this purpose, as well as in its use as a pigment, it is essential that the iron content be as low as possible, preferably not to exceed 0.5%. In acidic furnaces the coarsely crushed product is required for bedding. Boulders and large blocks of quartz are used in acid towers.

Quartz for miscellaneous industrial uses in California is derived from two sources, as boulders either from glacial deposits or that resulting from the disintegration of rocks in which quartz is abundant; and second, from veins and deposits of the mineral.

The cheapest source by far is the boulders, which require only to be gathered and hauled to the point of shipment. Quartz has been mined, however, in large quantities from deposits in Amador, Placer, Tulare, Riverside, Kern, and Los Angeles counties, as well as some other places in the state. Boulders occur abundantly, particularly in the northern half of the state, in Calaveras, Placer, Alameda, Sacramento, El Dorado, and other counties.

No separate statistics of quartz production were kept by the State Mining Bureau prior to 1913, when a yield of about 4000 tons was reported. This includes only shipments from Amador, Placer, and Tulare counties, no figures being given for southern California deposits, so that it is difficult to determine the exact extent of this important industry. In California the value of the crude material varies from $1.50 to $6 per short ton at the point of shipment. The variation in value in each case depends upon the distance from rail and the relative ease with which the mineral may be mined or gathered. Statistics of production are customarily combined with those of feldspar, glass sand, quartz sand, crushed rock, rubble, etc. The industry in California is now of sufficient importance to justify the segregation of quartz from other substances.

Magnesite

The Fresno Magnesite Co. is now employing a crew of 10 men in development work at Piedra, Fresno County, California. A shaft has been sunk to a depth of 250 ft., and ore is being exposed in laterals at this depth. The old adit intersects the shaft at 150 ft. below the outcrop. About 500 tons of good ore is now on the dump, all of which was broken during this development period. The mine is conveniently situated for transportation, a spur of the Piedra terminal of the Santa Fe railroad extending within half a mile of the company's plant, which includes a kiln of the stack type, built of reinforced concrete and stone, the calcining capacity of which is 12 tons of burned magnesite in 24 hours. Oil-fuel is used. The hoist and other machinery are operated electrically, power being supplied from a recently-built line of the San Joaquin Light & Power Company. The production from this mine to date has been about 4000 tons, nearly all of which has been used by paper-manufacturers in Oregon or Washington.

The deposits of the Western Magnesite Company at Red Mountain in Santa Clara county, California, have been producing and shipping calcined magnesite for several months. Most of the output, it is understood, is being shipped to Chicago or other Eastern points.

At Cedar Mountain, in Alameda county, a lease has been given to San Francisco people on the magnesite deposits formerly controlled by the Jas. H. Swindell Magnesite Company.

A deposit near Porterville, in Tulare county, has been reported sold to B. J. Bither of the Pure Carbonic Gas Co. The ore is to be calcined, and the carbonic acid gas content recovered. Magnesite from Morgan Hill, Santa Clara county, has been calcined recently at the West Berkeley plant of the company, instead of limestone as heretofore, the CO_2 content saved, and the calcined product shipped to a paper-mill in Oregon.

The Rex Plaster Co. has acquired the deposits at Bissel, Kern county, near Mojave, and has erected calcining furnaces. The deposits are of sedimentary origin, the only ones of this character known in the United States. It is reported that the company has contracted for the sale of its entire output.

Miscellaneous

Among the mineral substances used in the manufacture of artificial stone are quartz, granite (red, black, and gray), dolomite, limestone, lava (red and black) slate, actinolite, jasper (red and white), manganese, magnesite, pumice stone, and mineral paints. These substances have also been used with success in plastering the exterior of buildings. An example of this kind of work may be seen in the residence of James D. Phelan at Los Gatos. The exterior of this building was plastered with a mixture of white portland cement and a coarse sand made by crushing white quartz.

The preparation of so-called ready roofing also requires the use of these substances, in addition to which are used mica, talc, soapstone, and other materials. The crude rock is ground, carefully sized by screening, and packed in bags for the trade.

A new use for borax is being advocated by the Pacific Coast Borax Co. Fused borax 'glass' is being placed on the market for welding metals.

An attempt is being made to extract magnesium chloride from the bitter brines at the works of the Long Beach Salt Co. near San Pedro. Analysis of this brine at 30°B. is as follows:

$MgCl_2$	= 17.8%	equivalent to	356	lb.	per	ton
NaCl	= 10.0	"	" 200	"	"	"
Na_2SO_4	= 8.0	"	" 160	"	"	"
$MgSO_4$	= 10.03	"	" 206	"	"	"
KCl	= 3.7	"	" 74	"	"	"
KBr	= 0.08	"	" 1.6	"	"	"
K_2SO_4	= 1.77	"	" 34	"	"	"
H_2O	= 48.42					

Most of the magnesium chloride of commerce is recovered as a by-product from the Stassfurt deposits in Germany. Except for small stocks on hand in this country, very little of this chemical is now available, and inordinately high prices prevail. A little has been manufactured in California by the direct solution of magnesite in hydrochloric acid, but no attempt was made to reduce this to its fused state. When fused it is extremely deliquescent and is packed in sealed iron drums.

Silica sand for use in steel-casting molds must be nearly pure silicon dioxide and must be made up of smooth rounded grains. Sharp edges have a tendency to adhere to the castings. Most of the sand used for this purpose on the Pacific coast is shipped from Illinois.

Points of View From Lake Superior

By P. B. McDONALD

Flotation is being applied experimentally to Copper Country ore. The idea of concentrating native copper by frothing might seem impracticable to an outsider, and so it is to the general run of Lake Superior ores. But down in the Porcupine mountains at the extreme southwestern end of the region, the copper is flaky and fine, being in sandstone and shale. The White Pine property of the Calumet & Hecla, concerning which several happy predictions have been made, is saving what copper it can in its new mill by the usual dressing methods, and later may attempt flotation or leaching to recover the present rather high loss of copper in the tailing. The White Pine Extension is going ahead with flotation experiments assisted by A. J. Houle, professor of metallurgy in the Michigan College of Mines, and, as in nearly all flotation trials, some surprising facts have developed. It may be remarked incidentally that Prof. A. E. Seaman is giving geological advice to the White Pine Extension in its diamond-drilling campaign.

The application of more complicated metallurgy to Michigan copper ores is further indicated by the work being done at the Winona mill. A modification of the Slater leaching process is being applied by the Western Precipitation Co. of Los Angeles. The Slater process has been tried experimentally on 'porphyry' and non-roasting ores; it involves a cyclic treatment using chlorides and electrolysis. The Winona ore, while of amygdaloidal character, is finer and flakier than the usual Lake Superior copper, perhaps by reason of metamorphic crushing. The Winona mill, built several years ago, has undergone much change and experiment. A theoretical description of the Slater leaching process for copper ores by H. W. Morse appeared in the Mining and Scientific Press of January 24, 1914.

Unusual interest is being taken in two exploratory enterprises in the Copper Country. The Keweenaw Copper Co. in its sinking near the old Phoenix mine is said to be getting satisfactory showings of copper. William Uren, formerly with the Calumet & Hecla, is in charge. Keweenaw Copper is an expression of the faith of Messrs. Cole and Hoatson in the reviving of copper mining on Keweenaw point. A number of Duluth and Lake Superior people hold stock in Keweenaw Copper, as both Messrs. Cole and Hoatson have many friends. The other case is that of the Naumkeag Copper Co.'s shaft, at West Houghton, under the direction of Sidney Lang, with which operation J. Parke Channing and the Lewisohn interests are connected. This shaft is so close to Houghton's main street that the operations are watched daily. Close propinquity to a mining town is stimulating to mining developments. For instance, as James MacNaughton of the Calumet & Hecla once said, the Isle Royale mine, which is convenient to Houghton, was developed before its time, that is, years before modern efficiency made the property profitable.

Hard hats (but not boiled shirts) were furnished to the miners sinking the Woodbury shaft at Ironwood, Michigan, by the Newport Mining Co. These were for preventing head-wounds, much as the French soldiers are wearing light steel hats for protection against shrapnel. A discerning English writer has pointed out that in light of the many instances where letters, a Bible, or a coin, in a soldier's pocket have saved his life (ex-President Roosevelt's was saved at Milwaukee in 1912 by the bullet being retarded by his papers) it is strange that light armor for modern soldiers has not been adopted before. In the case of the Newport mine, the hats were made of felt treated with resin and shellac, making a surprisingly hard surface. They proved satisfactory for diminishing the effect of falling rock fragments, a certain amount of which cannot be prevented in a deep vertical shaft such as the Woodbury.

The question is sometimes asked if Safety Departments and Safety First precautions really have a practical effect in reducing accidents. This is pointedly answered by the record of the Cleveland-Cliffs Iron Co. of Michigan. In the four years since the Safety Department was established, there have been 30 fatal accidents in the company's dozen or fifteen mines. During the previous four years there were 55 fatal accidents. The total number of employees has steadily increased, and no large catastrophes intervened to affect the average irregularly. Following is the detailed classification of the company's fatal accidents in the last eight years:

Year.	Deaths ascribed to trade risk.	Deaths ascribed to negligence of the company.	Deaths ascribed to negligence of the workmen.	Total.
Without Safety Department				
1907	4	0	13	17
1908	3	2	1	6
1909	8	1	4	13
1910	6	5	8	19
	21	8	26	55
With Safety Department				
1911	2	1	2	5
1912	0	3	1	4
1913	3	1	7	11
1914	8	0	2	10
	13	5	12	30

This reduction of fatal accidents was accomplished by the permanent employment of a capable man to visit the mines and make recommendations as to safety, which were referred to the superintendents from the company's office in Ishpeming. Particular efforts were also made to secure the co-operation of the miners by conferences with committees of miners, inspections in other mines, and the ordinary publicity methods of teaching 'Safety First.'

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Alumina constitutes about 15% of the earth's crust.

The terms 'potential' and 'voltage' are synonymous, and mean electrical pressure.

The terms 'kilovolt-ampere' (kva.) and 'kilowatt' (kw.) represent input and output respectively of an electric generator.

Winms at small mines should be provided with some arrangement to prevent running back of the bucket used in hoisting ore, waste, or other material.

Open-pit mining (steam-shovel work) is much safer than underground systems; in the former the crews employed are small, and the quantity produced per man is enormous.

Factor of safety in steel hoisting ropes when newly installed in shafts less than 3000 ft. deep should not be less than six; and when the factor of worn ropes is below 4.5 they should not be used.

Loose timber should not be allowed to accumulate in main drifts of mines, as in case of the workings being flooded this material floats about, resulting in injury to men, or blocking cages in shafts or other equipment.

The slide-rule is suggested as a means of computing rock analyses, where certain phases of petrographic and metamorphic work require conversion of analyses into the corresponding approximate mineralogical compositions.

Air-receivers should be blown out at least once per day, so as to remove any accumulation of grease, oil, or other material likely to cause an explosion. The temperature of such receptacles should not be allowed to rise over 250° Fahrenheit.

White chert in the northern deposits of the Cuyuna iron range of Minnesota is often so thoroughly disintegrated that it resembles white flour, which, when in any quantity, will flow like quicksand. This material must be washed from the iron ores.

Hard hats should be worn by men working in shafts. At the Woodbury shaft of the Newport mine, Ironwood, Michigan, the miners were supplied with a hat made of felt treated with resin and shellac. Such hats are hard enough to resist a severe blow.

Mica occurs in 20 States as probable commercial deposits. The matrix of mica is pegmatite, a rock allied to granite in composition, but of much coarser texture. Such pegmatites are associated with crystalline rocks, either ancient metamorphic or igneous rocks. The absence of such rocks indicates the absence of good mica deposits.

Improvements introduced into cyanidation are generally considered to have been mostly mechanical, but J. E. Clennell considers that by a study of the recent history of the cyanogen compounds from a somewhat broader standpoint, it will be found that considerable additions have been made, not only to our knowledge of their chemical properties, but also to their applications for industrial purposes. The treatment of carbonaceous ores and by-products, electrolytic regeneration of cyanide, effect of mineral ingredients in water on cyanide consumption, fixation of atmospheric nitrogen, conversion of cyanamides into cyanides, production of cyanogen compounds from nitrogenous gases by catalysis and otherwise, and production of these compounds from gaseous mixtures by absorption with a metallic salt are all of recent investigation, and of importance to cyanidation.

Back-geared motors are increasing in favor at many mills and other works. From as far away as the Benguet district of the Philippines to the new mills at Rochester, Nevada, and Grass Valley, we hear of them being installed. Why is this method of power transmission gaining in popularity? Some of the reasons are as follows: In ordinary motor-driven plants countershafts are necessary for speed arrangement. These absorb power and necessitate the construction of wood or concrete foundations of some kind, which often are a nuisance, making everything too cramped. Additional belts are also required, with some form of tightener to ensure their adhesion to the pulleys. The running of many line-shafts and belts adds considerably to the vibration of a plant. The back-geared motor may be placed in any situation, so long as the foundation is good. The motor is of the squirrel-cage design, which ensures good results under severe conditions. At the back of the motor are cast two journals in which revolve the spur-wheel gear and pulley shafting, making a self-contained unit. The pinion-wheel is on the armature shaft, and both gear-wheels run in oil or grease in a tight cover. There is no danger, and little noise. The motor drives any unit, such as a crusher, five or ten stamps, or a tube-mill, by means of a belt. As the motor is on a sliding base the belt may be tightened without any trouble, no straining jockey-pulley being required. The individual back-geared motor is better than a large ordinary motor driving a counter-shaft, from which belts drive the units desired. The back-geared motor is of low speed, and the belts are usually short and heavy. Compared with the old driving methods, that is, one large motor, etc., there is a saving of fully 10% in current. The wear on gear is negligible, that at the MacNamara at Tonopah showing no perceptible wear in two years. These motors are made from 10 hp. upward, and may be used for driving any machine with entire satisfaction.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

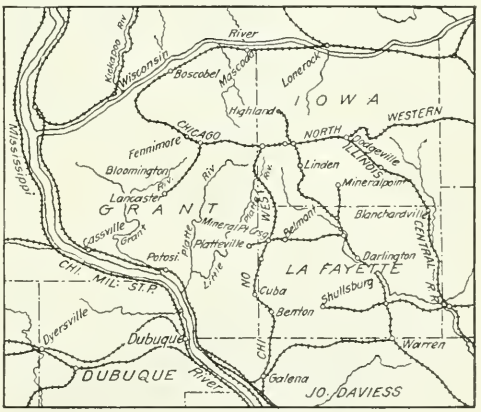
Floods Hamper Operations.—Prices of Zinc Products.—Peculiarities of the Market.—Results of High Prices.—Lead, Pyrite, Zinc Carbonate.—District Outputs.

The Missouri zinc region was not the only one to suffer from heavy rains in September, as the districts around Platteville suffered the same in the last week of the month, especially in the southern parts of the field bordering upon LaFevre river, where most of the large mines are situated. Many producers were seriously hampered by the waters, mine and mill equipment and reservoirs being seriously damaged, while the washing away of bridges and culverts tied up the main lines of railway traffic for several days. Unwatering of the mines was imperative, requiring in several cases weeks of constant pumping operations to put the mines back on a producing basis. At Galena, Illinois, the LaFevre river overflowed its banks, the lower or levee area of the city being submerged to a depth of six feet, compelling the use of skiffs on the main streets of the city.

From the substantial gains in the price of metal from about $10 per cwt. in the first 10 days of the month to $14.50, St. Louis, at the close, it would be inferred that this would have a tendency to increase the price of blende, coupled with a probable curtailed output for several weeks, but the contrary proved true. Further inroads were made into the price of blende, the top range of $70 to $80 per ton received in this field being lowered to $66 to $75. Just why this cut should be made at such a time was not explained properly, since the base range in the Missouri zinc districts held firm all the month at $70 to $80 per ton of 60% zinc content, the standard by which values are based in this field. High-grade product was raked clear of bins at all points, and the buying during the month revealed the fact that lower valued material was finding a ready market. Producers who had piled up a large reserve of lower-grade ore, which they have been compelled to carry for months, are facing the music manfully, because barred from active participation in the selling, and it is hard to believe that they will part with their output, if that were really the move a lower price standard had in view. The reserve at all points in the field at the beginning of the month was slightly in excess of 10,000 tons, and this was reduced during the month to about 7000 tons. Production up to the time that heavy rains interfered was excellent, while deliveries were even better. Bad roads immediately isolated all outlying producers, for which reason some of the districts in the northern half of the field entirely failed to report for two weeks.

One very interesting bit of information came from Luther V. Rice, general manager of the Fields Mining & Milling Co., in the Shullsburg district. This company is made up of officials of R. W. Hunt & Co., engineers, Chicago, who have developed two large mines here, on one of which recently a $75,000 modern plant was erected. In addition, a separating plant was added, and it is in connection with this separating process that the news is concerned: "Handled first 10 days 154 tons 18 to 20% ore, worth about $5 per ton, but absolutely unsaleable. Recovered 52 tons 54% zinc ore sold for over $6000. Roasting and separating cost $300." In other words, Mr. Rice means to convey the impression that he sold this ore under a contract agreement with the New Jersey Zinc Co., receiving under the terms of his contract $111.11 per ton for 54% zinc concentrate, while at that very hour $70 per ton was held out as the price for ore assaying 60% zinc content. This is not true in all instances of ore sold from separating plants in this field. Last June Mr. Rice sold 42% ore for $156.11 per ton under the same contract. Another operator, now the general manager for an Indianapolis mining corporation, interviewed during the month, admitted that he was receiving more for 48% green concentrate than he could obtain for 60% material in open market, so that it would appear that firms with foresight enough to provide themselves with contract arrangements to meet the present abnormal conditions displayed great wisdom. Substantial advances were made at several points in the field in the commencing of new separating plants, giving an outlet to a considerable quantity of crude zinc ore, which must, within the next 30 days, greatly relieve the situation here, as it will practically eliminate the surplus ore now accumulated.

Big profits follow the sale of blende at current quotations,



THE WISCONSIN ZINC REGION.

and the trend in all branches of the industry for several years past has been to secure maximum efficiency at minimum cost, and an average covering all ores produced in this region, both in the dry and under the water-levels, is now a little over $8 per ton, which includes overhead charges and cost of administration. The profits made during the past year gave large dividends, and the greatest period of mine development this field has ever known is under way. In the Benton district alone about 40 drill-rigs are busy. New plants, necessitating large quantities of mining, pumping, and concentrating machinery, are going up at several points; and as many more have been planned for construction before the end of the current year. The transition from a great low to a high-grade zinc-ore producing area by means of better methods of concentration has been accomplished so quickly and well that all are very pleased. Better roads are being constructed to enable haulage during the spring and autumn rains, when the markets may be inviting enough to stimulate prompt delivery of finished product.

Prices for lead concentrate held for a time at about $45 per ton, but a gain was made to $50, offerings which had held for several months. Producers saw no reason to part with

their products, and the reserve at all points was close to 3000 tons.

Pyrite was in poor demand. Crude ore production failed entirely for the month, and such sales as were reported came from the sale of fines recovered as by-product of separating plants; $3.75 to $4 per ton base of 50 units held all the month.

Carbonate of zinc ore producers met with discouraging conditions. The quotations offered by Missouri buyers for calamine ore govern quotations in this field on carbonate of zinc ore, and the highest prices ever recorded were registered, $70 per ton at one time obtaining for 40% ore. Competition developed in one quarter, but such sales as were made went to the Lanyon Zinc Co., a new buying factor as far as this product is concerned. The New Jersey Zinc Co. contends it cannot afford to pay high prices for carbonate ore to convert into 5-cent white oxide. Miners are loath to continue operations against no demand, and production fell off, considerable ore being carried over. The New Jersey Zinc Co., operating with two drills in an entirely new quarter in the Highland district, discovered one of the greatest continuous deposits of this class of ore ever found in the State. The range was proved on a line for more than half a mile, with the rigs still going. The development of this deposit will follow on a very elaborate scale.

The following deliveries of ore were made during September, two working days yet to be added:

Districts.	Zinc, pounds.	Lead, pounds.	Pyrite, pounds.
Benton	14,292,000	.....	.....
Cuba	3,762,000	.....	1,712,400
Mifflin	3,902,000	.....	.....
Galena	2,964,000	.....	.....
Hazel Green	2,446,000	.....	.....
Linden	1,984,000	....	.....
Platteville	1,718,000	.....	.....
Shullsburg	832,000	.....	.....
Highland	384,000	.....	.....
Dodgeville	84,000	80,000	.....
Mineral Point	90,000	.....	.....
Potosi	54,000	.....	.....
Total	32,512,000	80,000	1,712,400

The gross turn-in of raw ore for the month exceeded 28,000,000 lb., net refined ores and green concentrates from mine to smelter, and separating plant to smelter for the month 18,250,000 lb. The Mineral Point Zinc Co. delivered 3,390,000 lb. of high-grade separator ore to smelter at DePue, Illinois, which is not included in the table above.

The Mineral Point Public-Service Co. completed its main transmission-line to the extreme north end of the field. Considerable new equipment is being erected at many points.

TEXAS

Copper, Zinc, and Quicksilver Prospects.—Oil.

There is a revival of prospecting in the region east of El Paso, especially north of Allamore and north and north-west of the Van Horn, where considerable copper ore has been extracted and shipped by the prospectors. Last week the Pecos mine, 18 miles north of Van Horn, in the Diablo mountains, shipped four cars containing 26 to 28 tons each, averaging $20 gross in copper.

About five miles north of Kent, a zinc prospect is being opened. It looks pretty good. A small shipment has been made.

The Terlingua quicksilver district is working full time, with good results. Several new quicksilver prospects have been found in the district, and prospecting is active.

Owing to the advance in the price of oil new life has been given the prospecting companies, especially at San Antonio, Taylor, and Strawn.

CRIPPLE CREEK, COLORADO

Prospects at Straun Mountain.—Lessees' Results at the Isabella and Lower Dead Pine.—Vindicator and Portland.

There has been considerable prospecting during the past few months at the south-east end of the district, in the vicinity of Straub mountain. It is reported that two low-grade veins have been opened for a considerable distance in the Maybelle property. It is expected that a company backed by Eastern capital will start more extensive operations during the early part of next year.

Carnduff and Duncan, lessees of the Lower Dead Pine mine on Battle mountain are extracting good ore from the Dorothy vein. These lessees are now working from the 10th level of the Gold Coin shaft. This level is about 200 ft. lower than the bottom of the Lower Dead Pine shaft.

It is understood that A. Pearce and associates have obtained a three years' lease on a large portion of the Prince Albert estate on Beacon hill. New development work on an extensive scale will soon be started on this old-time producer.

The Vindicator Consolidated company claims to have made a new record for production during September, having sent out nearly 5900 tons of ore. An important discovery has been made on No. 18 level of No. 1 shaft, where a cross-cut exposed No. 1 north vein, and proved the extension of the rich ore-shoot developed on No. 16 level. The company has declared a dividend of 3c. per share, equal to $45,000, payable October 25.

The Portland Gold Mining Co. will pay 3c. per share on October 20, amounting to $90,000.

It is reported that during September lessees at the Isabella produced a little over 2000 tons of ore valued at $45,000 gross. The Isabella company is to install new concentrating machinery in its mill. As soon as the necessary changes have been made, a considerable quantity of low-grade ore from the mine and dumps will be treated.

Within a few days the Red Cross hospital at Victor will be transferred to the Portland-Vindicator commission. These companies will make some changes, and the result will be one of the best hospitals in the State. The acquisition of this institution is in keeping with the policies of these two companies, as was announced about August 1 in a circular to their respective employees.

LORDSBURG, NEW MEXICO

Review of Mining in the State: Burro Mountain, Santa Fe, Chino, Eighty-Five, and Waldo Mines.—Steins, Luna County, White Oaks, Pinos Altos, and Mogollon.

Improvements planned by the American Smelting & Refining Co. for its El Paso smelter reflect the state of mining in the South-west. The new equipment will cost over $300,000.

Before the end of the year another large copper producer will enter the field, namely, the Burro Mountain Copper Co. of Tyrone. Mill construction is progressing rapidly, besides company dwelling houses, stores, hospital, etc. The mines are being equipped with electric haulage and hoisting facilities. Over 500 men are on the company's payroll at present.

In northern New Mexico the Santa Fe Gold & Copper Co. is doing well, and is producing over 300,000 lb. of copper matte per month. Reports from San Pedro, where the company operates, state that the profits for the past quarter were $74,130.

Chino continues to yield its usual amount of copper, and it is thought that an extra dividend of $3 per share may be paid. This, as well as all other New Mexico metal mining companies, has not been troubled by the Western Federation of Miners, and it is hoped that such will not happen.

In the local (Lordsburg) mining region there has been little change in the last two months. The Arizona & New Mexico railway spur is completed, and hauling ore from the Eighty-

Five mine. During September 232 cars of copper ore were sent to the El Paso and Douglas smelters, but during October the output will probably be doubled, as the mines were closed at various times owing to break-downs and installation of new machinery, as well as poor railway service, during September. The Eighty-Five Mining Co. has purchased the Atwood mine from the Atwood Copper Co., and has two diamond-drills prospecting on the main vein. The deal is said to have involved the sum of $100,000. The Atwood mine adjoins the Eighty-Five property on the east, and is developed by a two-compartment shaft to a depth of about 400 ft. The mine has been operated spasmodically for the past 20 years and at times has been the largest producer here. The ores are lean as far as development work has gone, and only during a period of high copper prices has the operation of the mine been economical. The Atwood vein is the most prominent, and well defined in the Lordsburg district. With the acquisition of this mine the Eighty-Five now controls practically the best properties in the Virginia district.

The Waldo lead concentrating-plant has been closed down pending mine development work. During the operation of the mill high recovery was made, but, owing to the hardness of the surface ores, crushing was troublesome, and the company will now make an effort to block out a large tonnage in its mines.

Crocker and Randall are shipping regularly from the Nellie Bly mine at Leidendorf, and D. W. Briel is successfully operating the Robert E. Lee mine in the same camp.

Development work still continues at Lee's peak, where the Monte Rico and Octo mining companies hold valuable claims.

At Steins, Creswell and Moffitt are shipping from the Johnnie Bull mine. Their ore is high grade.——W. Charles is shipping lead ore from the Oldem mine to the El Paso smelter.——Mining men from Globe and Miami have been through the Steins field, and have proposed a consolidation of some of the most promising copper properties, and operating them on a large scale.

A new company has been organized at Steeplerock to operate the claims held by George A. Kalar; it is known as the Eclipse Mining & Milling Co.——In the same district George H. Utter is purchasing larger equipment for the operation of the Jim Crow mine.—David Gough has taken a lease and option on the Gold Crown mine near Steeplerock.

Luna county is gradually coming into prominence, and several important transactions have been completed in the last two weeks. The Saddler zinc mine at Cook's Peak has been sold to Holzmeyer and Gunther of El Paso, and will be operated on a substantial scale. Shipments will be made from the new Spaulding station to Oklahoma zinc smelters.——The Azure Mining Co., of Tyrone, has entered the Tres Hermanas district and has taken over the Contention mine. M. L. and J. Doby are doing shaft sinking for the Azure company on contract.——Two new mining companies have been organized at Deming, namely, the American Spelter Co., incorporated by D. S. Robins and J. S. Vaught, and the Royal John Mining Co., with J. C. Watson as agent.

An important transaction is reported from White Oaks, in Lincoln county. It is stated that the North and South Homestake and other producing mines have been taken under option by Richard Wrightman of Chicago. At Jacrilla a gold discovery of importance has been made by William Mehrman.

Activity in the Pinos Altos district of Grant county is increasing. Stauber and Wright are operating a new mill, and employing from 40 to 60 men. They are making high recovery on the base ores, and are treating a large amount of custom ore.——The Tip-Top mine has been leased to Baker and Newman of Central, who have begun development work.——Egbert, Case, and Whidden are operating the Gray and Copper Jack properties under lease, and are driving an adit a distance of 275 ft. They have cross-cut some good veins.——The Hardscrabble mine is under operation now by Janes, Wilcox, and Docker. Good ore has been opened at a depth of 50 ft., averaging 26% copper and 20 oz. silver. The company has shipped 800 tons of ore to date. F. V. Bush, of Lordsburg, has the sale of this property.——A new hoist is being installed by Watkins and Welch east of the Hardscrabble mine.——W. Stevens is operating the Garfield mine with a new hoist, and is getting into good ore.——Doyle & Co. are developing a 14-in. vein in the Manhattan adit, and propose to soon put on a large number of men.——W. H. Mills has leased the property held by him to a Magdalena mining man who is to install a gasoline hoist.——Peterson and Esplane are shipping concentrate from their mill.

The 250-hp. plant of the Empire Zinc Co. at Hanover has been completed. Work is progressing well in the new ore-treatment plant. The power-house is equipped with a Snow-Deisel type oil-engine.——The Monte Cristo mines at Gold Gulch have been sold by Frank Phelps to Frank G. Wilson, of Oregon. His son will have charge of the work.——J. W. Bible is operating the Modoc and other mines at Fierro under lease from the Phelps-Dodge Co. The Katy Mining Co. is doing extensive mining in the same region.——The United States Copper Co. at Hanover is preparing for a resumption of operations.

Conditions remain unchanged in the Mogollon district. Regular shipments of gold and silver bullion are being made from Silver City. It is proposed to have the new bridge over the Gila river completed by March 1916. The El Paso Bridge & Iron Co. received the contract for the erection of the bridge, and has begun work. A passage over the Gila river has been one of the hindrances to progress in the Mogollons, but this will be overcome with the completion of the bridge.

The Memphis & Red River Mining Co. has purchased the mine and mill machinery of the Trinidad Mining Co. at Red River, and is getting same in condition for operation.

GOLDFIELD, NEVADA

New Exploration by the Merger.—Jumbo Extension. Kewanas, Spearhead, Sandstorm-Kendall.

After an examination of its property and adjoining ground by G. H. Garrey, geologist of New York, the Goldfield Merger Mines Co., in charge of Willis Lawrence, has started a new cross-cut at a depth of about 1175 ft. for the purpose of intersecting the ore-channel exposed in the Jumbo Extension mine. The formation is expected to be cut near the west side-line of the Sunflower claim of the Merger. This work will be continued through the Grizzly Bear shaft of the Goldfield Consolidated, but later all operations of the Merger company will be conducted through its own shaft, which is nearly 1800 ft. deep, and equipped with one of the best surface plants in Nevada.

On the deepest level, 1017-ft., of the Jumbo Extension mine, a cross-cut is being driven from the most south-easterly workings to connect with the Velvet or No. 2 shaft, when the latter has reached this depth at the end of the year. The cross-cut is in the shale, but shows ore assaying from $8 to $12 per ton, and is being diverted slightly from its most direct course to follow this ore.

In the Kewanas the drift at 840 ft. in the northern part of the Kewanas claim, has followed the ore-shoot for over 160 ft.: it shows from 18 in. of $80 to 5 ft. of $25 ore.

The Spearhead Gold Mining Co. has decided to proceed at once with development on company account. The first work will be to sink the main shaft 250 ft. deep to reach the shale-contact, at an estimated depth of 1000 ft. Mr. Bruce is superintendent.

A large pump is being installed in the Sandstorm-Kendall to permit driving of the cross-cut from the bottom of the winze at 700 ft. depth.——Development continues at the Silver Pick, Great Bend, and Black Butte.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

At the United States Assay Offices at Boise, Carson City, Helena, and Salt Lake City, the Government has reduced the charge of $3 for each metal determined in an ore to $1. This will benefit prospectors. Tin and tungsten are to be assayed, but the charge for these will be higher.

ALASKA

Bulletins 622 E, F, G, and I of the U. S. Geological Survey, by B. L. Johnson, Stephen R. Capps, Henry M. Eakin, (2) respectively, deal with certain parts of Alaska. The first covers mining on Prince William Sound and the gold and copper deposits of the Port Valdez district. The lode-mining districts of the Sound may be grouped into two concentric belts, concave southward, the outer one including the gold, and the inner one the copper areas. In 1914 there were eight gold and two copper

CALIFORNIA

Bulletin No. 70 of the California State Mining Bureau has just been published. With index and 21 maps it covers 184 pages. The mineral production for 1914 and mining law appendix are the principal sections. New features of the appendix are the inclusion of details of the new department of petroleum and gas, for regulating the drilling of wells; (this has also been published in pocket form with 34 pages), the new corporation license tax law, and sub-heads on assessment work. In the mineral section brief descriptions of the occurrences, characteristics, and uses of many minerals are given. An interesting chapter discusses magnesite. The main chapters are fuels, metals, structural materials, industrial materials, salines, and mineral production by counties. The maps are good. The total value of all products in 1914 was $5,208,086 less than in 1913, due to the general depression. The value was $93,436,553, of which petroleum accounted for slightly over 50%, and gold 22%. County production varied from $300 in Tehama to $28,047,957 in Kern. Details are as follows, in tons except where given otherwise:

Substance.	Quality, tons.	Value.
Asbestos	51	$1,530
Barytes	2,000	3,000
Bituminous rock	66,119	166,618
Borax	62,500	1,483,500
Brick, number	270,791,000	2,288,227
Cement, barrels	5,109,218	6,558,148
Chromite	1,517	9,434
Clay	179,948	167,552
Coal	11,859	28,806
Copper, pounds	30,491,535	4,055,375
Feldspar	3,530	16,565
Fuller's earth	760	5,928
Gems	.....	3,970
Gold	.....	*20,775,000
Gypsum	29,734	78,375
Infusorial earth	12,840	80,350

Zinc, pounds	399,641	20,381
Total	.....	$93,436,553

*Estimated.

†Including granite, macadam, rubble, paving blocks, sand, and gravel.

All California miners should get a copy of this publication.

Amador County

San Francisco and Sacramento people have formed the Sutter Creek Mining Co. with a capital of $300,000 to develop the East Eureka mine at Sutter Creek.

Butte County

In the long suit of H. T. James and others *v.* the P. B. Steifer Mining Co. to restrain the company from assessing stock and from selling unpaid assessed stock to pay assessments, the defendant won.

Calaveras County

Development in the Calaveras copper mine at Copperopolis continues most encouraging. On No. 4 level south the hanging wall shows 15 ft. of 34% ore, with streaks assaying 9%. A shipment of concentrate on September 23 averaged 11.12%, and returned $1098 net. There are 106 men employed.

Eldorado County

A great area of buried river gravel deposits exists in this county, but capital is required for its exploitation. Early in November L. A. Bender and C. Wright are to start driving an adit to cut the channel that runs through Newtown ridge at the head of Missouri canyon, three miles west of Pleasant Valley on the road to Diamond Springs.

Nevada County

The new 20-stamp mill at the Brunswick is nearly complete. ——Ten stamps are to be added to the Golden Center mill; a cyanide-plant is being considered.—— Owing to an accident to the motor-driven pump the Central Consolidated mine at Greenhorn was partly flooded last week.——The Ben Franklin and Alaska mines have been bonded to New York people.

The old Yuba mine at Maybert, seven miles above Washington idle for five years, has been purchased by the Dinero Mining & Power Co. of San Francisco. The shaft, 960 ft. below the adit, is to be unwatered, and deepened. W. J. Connors is in charge. The property, formerly controlled by Haggin and Hearst, has produced over $2,000,000.

Placer County

The city of Auburn is defendant in a suit for $20,000 damages, brought by J. Malmberg, who alleges that sewage dumped into the Auburn ravine prevented his mill being worked.

Shasta County

(Special Correspondence.)—The Arps copper mine near Copper City has been taken under bond by C. L. Wilson, who has started work with a small force. The property is near the Bully Hill claims, and has been slightly developed by several short adits and drifts. It is owned by William Arps of Copper City and R. M. Saeltzer and others of Redding.

The Mammoth Copper Co. has completed surveys for the new tramway from the Stowell mine, and construction is about to begin. The line will connect with the Balaklala tramway, near Coram, from which point the ore will be sent direct to the Kennett smelter.

Ore averaging 6% copper is being shipped from the Greenhorn mine, near Tower House. The orebody recently intersected in a lower adit is developing well. Better shipping facilities have been installed at the mine and a larger output will be commenced shortly.

J. P. Erhart, of Ono, has acquired full ownership of the North Bank quartz mine, and is preparing to work the claim more vigorously.

Considerable work is under way at the Telluride Con. group, near Middle Creek. Winter supplies are being shipped in. Anton Herzlieb is managing director.

Equipment for the Gardella dredge on the Saeltzer ranch, about four miles from Redding, is arriving, and excavation of the pond is nearly finished. It is proposed to start operations before the year ends. The old boat of the U. S. Dredging Co. has been moved to the farm of Perry Marks, below Redding. A large deposit of gold-bearing gravel has been prospected, parts of the channel containing 10 to 40c. per cubic yard.

Operations have been curtailed at the Gladstone mine, near French Gulch, and the working force reduced. Prospecting is proceeding from the lower levels, and the shaft is being deepened.

Prospecting of copper claims is active, particularly in the East Side field, where several properties in the vicinity of Copper City and Herault are commanding attention.

Gold mining is rather quiet, with the exception of increasing activities on the part of dredging concerns.

Redding, September 27.

SISKIYOU COUNTY

One of the largest mining deals that has been completed in this county for years was that when M. E. Olsen and others of Seattle bought the six claims of H. B. Wintering and F. H. Osgood on south Russian creek, Salmon river district, for $85,000. The Big Cliff Mining Co. has been organized to develop the property. A large quantity of medium-grade ore has been opened, and a 200-ton mill is to be planned.

The Klamath River Dredging Co.'s new boat will soon be finished. It has been designed to handle the large boulders met with in the Klamath river.

COLORADO

CLEAR CREEK COUNTY

During September the Chamberlain-Dillingham sampler at Georgetown shipped 400 tons of ore and concentrate worth $35 per ton. This works does not handle all of the products of the district. Zinc ore was not shipped, and is being stored at the various mines and mills.——Developments in the Mineral Chief are encouraging.——Lessees at the Waldorf are shipping good ore.——The Edison process is working at the Silver Plume Reduction Co.'s mill, and a good recovery is being made.

GILPIN COUNTY

Pennsylvania steel people have purchased for $16,000 the Rogers upper tract of 160 acres of tungsten-bearing claims in the Nederland district. The property has been a large producer.

LAKE COUNTY (LEADVILLE)

Most of the large stopes at the Penrose shaft of the Down Town property are drained.——The St. Louis adit in Big Evans gulch is the largest producer of high-grade gold ore in the district. Zinc sulphide is being developed also. This ore is being treated at the Leadville District mill.——At the Fortune mine the old shaft has been re-timbered to 1000 ft. depth. A new hoist has been installed. Zinc carbonate is to be extracted from the 600-ft. level. James McNeece is in charge.——The Mt. Champion in Lackawanna gulch is producing up to 150 tons of ore per day, the mill treating 100 tons. A new electrically-driven compressor is at work.——Prospects at the Jennie June mine are good, and good gold ore is to be shipped.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

Although water has hindered work at the Marsh mine at Burke, development and mining proceeds satisfactorily. A new pump is to be installed. At 900-ft. a station 50 ft. long, 25 ft. wide, and 20 ft. high is being cut out. It will serve for pumping and storage of ore, etc. The new Nordberg hoist, of 2700-ft. capacity, is working well. The mill, near Wallace, has been overhauled, and treats 150 tons daily. A Callow flotation plant is operating. Since the improvements were made the recovery is $1.25 per ton better. The company employs 90 men in charge of W. E. Greenough.

On October 25 the Success company, Nine-Mile district, will distribute 6c. per share, equal to $90,000. The current year's total is $495,000. Lead-silver, then zinc, and again lead ores have been the products of this mine.

At the Independence Lead Mines Co.'s mine near Mullan, the No. 4 adit, now in 1000 ft., is to be extended 230 ft. to cut have been the products of this mine.

Development of and shipments of antimony ore from Coeur d'Alene mines continues, and is likely to become very important in this region.

MICHIGAN

THE COPPER COUNTRY

According to *The Daily Mining Gazette* the estimated output for September was as follows:

Mine.	Pounds.	Mine.	Pounds.
Tamarack	561,000	Hancock	159,000
Osceola	1,725,000	LaSalle	177,000
Ahmeek	2,225,000	South Lake	21,600
Wolverine	711,000	Isle Royale	900,000
Mohawk	1,359,000	Copper Range	4,600,000
Franklin	381,600	Quincy	2,000,000
Centennial	53,000	Calumet & Hecla	6,500,000
Allouez	848,000	White Pine	491,000
Mass	486,000	Lake	280,000
Superior	326,000	Winona	230,000

Shipments of mineral from the White Pine mill to the Calumet & Hecla smelter at Hubbell are made by water; but early in November transport will be by rail, as the C. & H. has let a contract for construction of two miles of track to connect the White Pine with the Chicago, Milwaukee & St. Paul road.

The Quincy is producing over 4000 tons of ore per day from three shafts. This will be increased when No. 7 shaft is complete. The eight stamps have a daily capacity of 5500 tons. The Hancock contributes 650 tons per day.

MONTANA

SILVERBOW COUNTY

Pumping has been started at the Emma zinc mine of the Anaconda company.

The North Butte mine is at normal production again, the daily output being 1350 tons of ore. An important development is reported on the lower level of the Jessie vein.

Wages at Butte in September amounted to $1,500,000, the Anaconda distributing $1,090,000, Butte and Superior, $170,000, and North Butte, $100,000.

NEVADA

CLARK COUNTY

The high price of zinc is having its effect on the Good Springs district.——The Yellow Pine company is shipping 1500 tons of zinc ore, and 200 tons of lead concentrate per month. A dividend of 10c. per share was paid on September 25. This is equal to $100,000, making $230,000 for the current year. The main shaft is 900 ft. deep.——The Empire Zinc Co.'s Potosi mine is producing 900 tons of zinc ore per month.——Ore-bins and a sorting-plant have been erected at the Green Monster mine. The monthly output of carbonate ore is 500 tons. Several adjoining properties are doing interesting work.——At the Bullion mine a 50-ton dry concentrating-plant is treating low-grade lead ore. A similar plant is being erected on the Anchor, and one has been ordered for the Sultan. There are six plants in operation or under construction in the district. ——Boston people have acquired the Doran and Zenzen mine on Pig Devil mountain.——A number of other mines are being worked by owners and lessees.

ELKO COUNTY

Jarbidge is busy and optimistic. The Bluster property is producing $10,000 gold per week.

LINCOLN COUNTY

The Prince Consolidated mine is now shipping ore at the rate of 12,000 tons per month. The cost of mining and loading on cars is $1.20 per ton. The three-compartment winze below 550 ft. is down 125 ft. Eventually it will act as a main shaft, as it is to be raised to the surface.

Nye County

Five companies and numerous lessees at Tonopah last week produced 9583 tons of ore worth $198,454. The Belmont, Extension, and Tonopah dispatched a total of $223,000 of silver. The earthquake, on October 2, which was felt in the mines of the district, caused considerable alarm, but did no damage.——Results at 1350 ft. in the Extension are excellent, there being 20 ft. of good ore at the end of west drift 502.——In the Rescue-Eula, the winze sunk on the vein below the 950-ft. level, is down over 40 ft., showing 12 in. of good ore.——In the Umatilla-Tonopah the diamond-drill is down 450 ft. below the 1200-ft. level. The country is mineralized, and is less broken than previously.

White Pine County

(Special Correspondence.)—The additional power-plant at the Nevada Consolidated is now working well. An increased output should result at the mill.

There is much activity in the eastern part of the county in tungsten mining. Probably 100 men are working while others are prospecting for new veins. A 65% product is said to realize $2000 per ton, whether scheelite, wolframite, or hübnerite.

The old Victoria copper mine, 15 miles north-east of Currie, in the south-west corner of Elko county, is being worked under a bond and lease by Seattle people.. It is said they are ready to commence shipments of 8 to 9% ore.

The Willow Creek Con. property, about 100 miles south-west of Ely, which has been taken over by Salt Lake people, is said to be developing satisfactorily. Some of the ore shows free gold.

Ely, October 7.

OREGON

Baker County

Shipments of ore and concentrates from Sumpter during the current month are expected to be large.——No. 2 boat of the Powder River Dredging Co. is nearly ready for work. It has 7.5 cu. ft. buckets, and was built by the Yuba Construction Company.

SOUTH DAKOTA

Pennington County

A tungsten property four miles east of Hill City has been sold by A. Wabel to the Chicago Steel & Iron Co. for $125,000. Prospecting and developing tungsten claims is fairly brisk in this district.

TEXAS

Culberson County

(Special Correspondence.)—A large deposit of sulphur has been discovered by W. A. Doyle of Dallas, 45 miles north-west of Riverton, near the New Mexico state boundary, and 18 miles from the Pecos Valley line of the Santa Fe railroad. A spur line will probably be laid down to the deposit. Mining will be simple, as the mineral occurs at a depth of 12 feet.

Riverton, October 1.

UTAH

Beaver County

The South Utah Mines & Smelters, successor to the Newhouse Mines & Smelter Co., resumed work on October 1. The property was closed in June 1914, after producing a good deal of copper. The mine is opened to 600 ft. by two shafts, connected by a 6300-ft. electric haulage-way. Ore assaying 1.8% copper has been opened at 600 ft. A 1000-ton mill is part of the plant.

In the Croff mine, Lincoln district, 3 ft. of carbonate of zinc ore has been cut, also 3 ft. of lead ore, but quite separate.

Juab County

Shipments from Tintic mines last week totaled 134 cars. At a depth of 300 ft. below the 600-ft. level in the Iron Blossom 10% copper ore has been cut. This is under a shoot which has produced ore for some years.——Extraction of $12 to $15 ore in the Dragon Con. near the Iron Blossom has been stopped until the Tintic Milling Co.'s plant is completed.——Lessees at the Yankee Con. are shipping rich zinc ore.

Salt Lake County

The output of the Alta-Cottonwoods district this year is expected to be over 120,000 tons of ore, a large increase over that of 1914. The Cardiff, Emma, Michigan-Utah, and South Hecla are the largest shippers. In the last named the ore-body at 225 ft. depth is 155 ft. long and up to 20 ft. in width. Eight raises are in ore.

The Michigan-Utah is to extend its adit, which is in 200 ft., to cut the City Rocks vein at a depth of 550 ft. The mine is producing a good tonnage of ore.

Summit County

A total of 9176 tons of ore was shipped from the Park City district in September, of which 2829 tons was from the Daly-Judge mine, 651 from the Daly West, 353 from the Silver King Coalition, and 1364 from the Silver King Consolidated.

The Snake Creek tunnel was advanced 345 ft. during September, and is now in 12,710 ft. in diorite. The vertical depth is 3730 ft. So far the opening has been straight, but it is now headed north-west for the Daly-Judge property, 2000 ft. away. The flow of water is 7947 gal. per minute. Additions are being made to the Daly-Judge mill. Good ore has been cut at 1200 feet.

Tooele County

Alleging that their live-stock and crops have been damaged by fume, and that agreements as to land purchases were not kept up, 26 farmers and their wives are suing the International Smelting & Refining Co. for $265,337 damages, and $39,781 for attorneys' fees, a total of $305,118.

The Ophir district is producing more ore than ever before. In August 131 cars of ore and concentrate were sent out. The Ophir Hill Consolidated has 11,000 tons of concentrate stored at the mill, shipping only enough to abide by its contract. Rich silver-gold-zinc ore is being extracted from the St. Clair lease on Lion hill, the yield since May being over $30,000. Leasing is employing 150 men.

WASHINGTON

Ferry County

At the Knob Hill mine at Republic there are 17 men employed and the monthly output of gold ore is about 350 tons. This goes to the Trail smelter. A shoot 300 ft. long, with 18 in. of profitable ore, has been opened on the intermediate level. In the lower adit this shoot is 150 ft. long. When electric power is available a shaft will be sunk to develop the property at depth.

CANADA

British Columbia

At the end of last week representative mining and business men of Spokane visited the Kootenai mining district.

At the south-eastern end of Moresby island, one of the Queen Charlotte group, 400 miles from Vancouver, the Ikeda Mines Limited is developing and extracting copper ore. The property was located nine years ago by A. Ikeda, one of the directors. In 22 months a net return of $58,823 was received from 5915 tons of ore. Development is done by adits. Suitable surface plant has been erected. The mine has been favorably reported on by engineers. At present 30 men are employed, and 50 tons of ore is shipped each month to the Granby smelter at Anyox. Two settlements in September showed the ore to assay up to 17% copper, 3.5 oz. silver, and 0.33 oz. gold. More men are to be employed and larger shipments made. This island is said to be well mineralized and worth prospecting. Heavy timber is growing, there is water-power, and plenty of game. Steamers call twice a month.

ONTARIO

When the 13 by 30-in. Buchanan crusher, 6 ft. by 16-in. ball-mill, 5 by 16-ft. tube-mill, five 32 by 10-ft. thickeners, and three 32 by 18-ft. agitators are installed at the McIntyre mill, the whole plant will have a daily capacity of 450 tons.

Diamond-drill prospecting is under way at the Old Huronia mine at Gauthier township.

In *The Canadian Mining Journal* for October 1 are two illustrated articles dealing with the Kowkash goldfield. An abstract of one has already appeared in the PRESS; in the other, by C. Spearman, he considers the area as promising for exploration. In many places the geological conditions strongly resemble the Porcupine district.

MEXICO

EL ORO

The Esperanza Mining Co. reports as follows for the period from April 1 to June 30: Development amounted to 1652 ft. on the first, second, and third levels of the Descubridora vein,

VENUSTIANO CARRANZA, DE FACTO PRESIDENT OF MEXICO.

raises above No. 3, 5, and 9 levels, and work on No. 14 and 15 levels of the San Rafael vein. Raise No. 3 above No. 2 level on the Descubridora was up 86 ft. in 60 in. of 2-oz. gold and 5.5-oz. silver ore.

'Coal Mining in Mexico' is the title of a paper by T. O. Forster Brown read before the North of England Institute of Mining and Mechanical Engineers. It consists of 42 pages, with illustrations and plans. Nearly all coal mining in the republic is done in the state of Coahuila, 100 miles from the international boundary. In 1912 there were three American, three British, and three Mexican colliery companies. In 1911, when affairs were normal, the output was 1,858,996 metric tons. The approximate consumption of coal in the country was 1,955,128 tons. Imports amounted to 846,981 tons. The revolution resulted in immense damage to the surface plants, as is testified by photographs.

To further help the work of Carranza in restoring order in Mexico, the U. S. government has placed an embargo on the shipment of anything that might be used by the Villa party in fighting; one lot has been held up.

PERSONAL

D'ARCY WEATHERBE is at Cobalt.

J. PARKE CHANNING is at Miami.

E. M. HAMILTON is at Virginia City.

FRANK H. PROBERT is at Salt Lake City.

ALGERNON DEL MAR is at Nelson, Nevada.

H. S. LEE has moved from Oregon to Haileybury, Ontario.

J. D. ROBERSTON, of Robert W. Hunt & Co., is here from St. Louis.

CLARENCE WOODS has returned from Alaska to Tuolumne, California.

ROBERT N. BELL, Inspector of Mines for Idaho, is at the Palace Hotel.

P. B. MOSSMAN of the American Refractory Co. has been here from Chicago.

CLAUDE FERGUSON has gone to Cherry, Arizona, to take charge of the Logan mine.

DIBRELL P. HYNES, who is with H. L. Hollis, of Chicago, is visiting the Exposition here.

PERCY MARMION has been appointed manager of the Swansea Vale smelter in South Wales.

SAMUEL S. ARENTZ passed through San Francisco on his way from Salt Lake City to Imperial, Arizona.

F. E. MARCY has resigned from the Mine & Smelter Supply Co. to engage in business on his own account.

BEN B. LAWRENCE, after a visit to Cornucopia, in Oregon, and Bingham, in Utah, has returned to New York.

BENJAMIN MAGNUS, lately manager of the Mount Morgan mine Queensland, has arrived here from Australia.

WASATU KONDO and M. YAMASHITA have arrived from Japan on a metallurgical reconnaissance in the United States.

G. R. LEWIS of Cripple Creek has been appointed general manager of the Copeland Sampling Co., succeeding W. F. VAN SANT.

J. H. MACKENZIE was on the *Mariposa* when she was wrecked off the British Columbian coast on October 1, without the loss of any passenger.

J. H. CURLE, who volunteered for military service early in the War, has been detached for special work with the Parliamentary Savings Committee in London.

THEO. P. HAUGHEY, accompanied by EDGAR N. FRIEND, both of the American-Oriental Engineering & Construction Co., sailed from Seattle early in October for Yokohama.

W. D. BURCHAM has left Shafter, where he was mill-superintendent for the Presidio Mining Co., in order to take charge of the re-opening of the Big Bend cinnabar mine in Terlingua district, Texas.

HUNTINGTON MILLER, manager of Lo Increible Mining Co., Venezuela, has recently returned from a visit to New York and is again in charge of operations at the company's mines, near El Callao, Yuruary district, Venezuela.

Schools and Societies

Members of the Utah chapter of the A. I. M. E. held their first annual meeting and banquet at the Hotel Utah, Salt Lake City, on October 4. During the evening C. W. Whitley, general manager of the American Smelting & Refining Co., was elected chairman of the local branch, Walter Fitch was elected vice-chairman, and Ernest Gayford, secretary and treasurer. Following the banquet, papers were read by J. M. Callow on the present state of the flotation process, and T. S. Carnahan on underground methods at the Utah Copper. Moving pictures were then shown of mining at Bingham, and milling plants at Garfield, and other works in the West.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, October 14.

Antimony	32
Electrolytic copper	19
Pig lead	4.75—5.70
Quicksilver (per flask)	$92
Spelter	16
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	26

ORE PRICES

Antimony: market weaker, 50% product, free from deleterious impurities, per unit.....$1.50

Tungsten: depending on quality, subject to negotiation, minimum 65% WO_3, per unit for spot.....30.00

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, October 14.—Copper is quiet, with no change; lead is steady at the same price; spelter is weak.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Oct. 7	49.62	Sept. 1	46.77
" 8	49.62	" 8	48.20
" 9	49.50	" 15	48.56
" 10 Sunday		" 22	48.85
" 11	49.50	" 29	49.29
" 12 Holiday		Oct. 6	49.64
" 13	49.50	" 13	49.55

Monthly averages.

	1914.	1915.		1914.	1915.

May	58.21	48.87	Nov.	49.12	....
June	56.43	49.03	Dec.	49.27	....

The above quotations indicate a steady market. Silver coinage executed in the United States in September was worth $717,000, using, say, 1,500,000 oz. Last week the Nipissing company sent 250,790 oz. to England via New York. Exports of silver from London to the Orient to September 22 were worth £3,376,250, against £4,520,500 in that period of 1914, a decrease of, say, 12,000,000 oz. Rains in India have been favorable.

COPPER

Prices of electrolytic in New York, in cents per pound.

Date.		Average week ending	
Oct. 7	18.00	Sept. 1	17.83

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	14.21	13.60	July	13.26	19.09
Feb.	14.46	14.38	Aug.	12.34	17.27
Mch.	14.11	14.80	Sept.	12.02	17.69
Apr.	14.19	16.64	Oct.	11.10	....
May	13.97	18.71	Nov.	11.75	....
June	13.60	19.75	Dec.	12.75	....

Exports of copper during the week ended September 25 amounted to 8,273,626 lb., valued at $1,568,448. France took 5,257,786 of this; England, 1,368,899; and Italy, 1,273,266 lb. Imports totaled 6,795,778 lb., worth $845,454. Peru contributed 2,538,827 and Chile 1,378,919 pounds.

Some September outputs were as follows: Anaconda, 22,800,000; Kennecott, 9,000,000; Greene-Cananea, 3,514,000, an increase of 600,000; Old Dominion, 2,538,000; and East Butte, 2,089,820 pounds.

Miami will pay $1 per share on November 15. An extra dividend is expected from the Ray. Greene-Cananea is expected to declare a dividend soon. Chino's earnings are at the rate of over $9 per share.

Michigan producers think that the Anglo-French loan will stimulate the copper business. Accumulations at Michigan smelters and docks amount to about 30,000,000 lb. This is not considered unusual at this time. Fully one-third is said to be sold.

ALUMINUM

The quotations continue to soar and 50c., New York, has been paid, while up to 52c. has been asked. In fact, fancy premiums have been offered and in some cases without inducing a sale.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Date.		Average week ending	
Oct. 7	14.00	Sept. 1	15.75
" 8	13.75	" 8	14.77

May	4.91	17.03	Nov.	5.01	....
June	4.84	22.20	Dec.	5.40	....

The demand for zinc ores in the Missouri-Kansas-Oklahoma region was very strong last week, prices for 60% product being up to $87.50 per ton. The output was 6169 tons blende, 188 tons calamine, and 993 tons lead, averaging $77.03, $55, and $51 per ton respectively. The total value was $546,148, and 41 weeks, $18,372,936.

In September the Butte & Superior produced 13,000,000 lb. zinc, a decrease due to 4 days' shut-down.

The Consolidated Interstate-Callahan's report for the year ended June 30, 1915, shows a profit of $1,591,773. The monthly output of concentrate is 6000 tons.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Date.		Sept. 29	90.00
Sept. 15	90.00	Oct. 6	90.00
" 22	90.00	" 13	92.00

June	30.72	40.26	Dec.	33.60	....

Tin was quoted on October 13 at 32.50 to 32.75 cents.

ANTIMONY

There is plenty of antimony to be had but the demand is quiet, and Chinese and Japanese metal is to be had easily at 28 to 28.25c., duty paid. Domestic antimony is offered at ¼c. less. To treat antimony ore from Alaska, Idaho, and Canada, a smelter is being erected at Seattle.

Eastern Metal Market

New York, October 8.

Some further large sales of copper have been made to manufacturers of munitions, but the trade in general has been quiet. An interesting development is the growing use of electrolytic where Lake had been regarded as indispensable. Prices have been maintained, despite a tendency to soften. The London market for electrolytic holds firm. Spot and near-by zinc continues scarce, and business has been restricted to flurries of small-lot buying. Lead has been dull, though quotations are steady at the level fixed by the leading interest. London has been more active than New York on account of selling to Russia. Tin declined in a dull market to 32c., but jumped to 33c. on October 6. Antimony is quiet and in plentiful supply. Aluminum is scarcer than ever and 50c. per pound and upward is quoted. Buying of all the metals has been in flurries, and more or less irregularity is shown in all directions.

Iron and steel have continued their amazing pace. In September the pig-iron production was 2,852,561 tons, or 95,085 tons per day. The previous high record was 92,369 tons per day, in February 1913. At the present rate of production the figures for this month will be even higher. It is probable that the production of both pig-iron and steel ingots will exceed 3,000,000 tons this month. Not only are the railroads more of a factor in the steel market, but improvement is seen in many directions not associated with war business.

COPPER

Since the heavy buying referred to a week ago there has been a lull in the market, though a few good deals have been reported this week, and some large inquiries are known to be existent. An ammunition maker took 1,000,000 lb. of Lake on October 5, at 18c., cash. All business of notable size continues to be with those having war orders. The fact that the activity has been shared only by the larger sellers has fostered an impression that the magnitude of the sales has been exaggerated, but nevertheless they have been made. The smaller producers and second-hands have not been doing much, and as a result they have become more and more inclined to give concessions in price, although 18c. cash, New York, is still the general quotation for both Lake and electrolytic. An old-timer in the metal market does not think, when circumstances are considered, it peculiar that Lake and electrolytic are quoted at the same level. First, he points out that Lake is usually sold for cash, and electrolytic, cash, 30 days, the latter terms being more to the advantage of the buyer; second, there is no difficulty at any time of obtaining electrolytic in any quantity, while the recent past saw a scarcity of prime brands, and with the scarcity large premiums were demanded. In the judgment of many, these premiums were exorbitant. A third point in the argument is that since the outbreak of the War, and even prior thereto, consumers have found that they can use electrolytic where they previously had supposed that Lake was indispensable. Because of its greater penetrability, Lake always has been used in the manufacture of high-grade cartridges, and will continue to be used where maximum quality is required. At the same time according to the student referred to, where millions of cartridges are to be used, largely in rapid-fire guns, some slight departure from the highest standards is reasonable to expect. It is notable in this connection that discussion at a meeting of the American Institute of Metals at Atlantic City, last week, brought out that 90% of the members present who formerly had used Lake copper had turned their attention to electrolytic, and that few of them would return to Lake if they had to pay a high premium for it. The London market for electrolytic continues steady at around £88, but standard is variable, and on October 5 was £17 under electrolytic. The exports in the first seven days of October totaled 4624 tons. The European stocks of copper were estimated September 30 at 23,628 tons, against 11,600 tons on the 15th, and 29,519 tons August 31.

ZINC

Spot and near-by metal is scarce, though the absence of any sustained business has caused prices to become a little easier in the past week. On October 4, 5, and 6, sellers would accept 14c., St. Louis, and 14.25c., New York; November can be done at 13.50c., St. Louis, and December at 13c., St. Louis. But little interest is taken in futures by consumers, and what business there has been in prompt has been in flurries involving no large tonnages. London quoted £69 on October 6. In the course of a few days London advanced £5, but even at £69 the foreign market is not on a parity with New York, when costs of import are considered. The rise abroad, of course, is a stimulating feature. The exports in the first seven days of October aggregated 1755 tons.

Sheet zinc is unchanged at 16c. base, f.o.b. smelter, subject to a discount of 8%, for cash and carload lots, and correspondingly smaller discounts for smaller quantities.

Following is a comparative statement of exports of spelter and zinc ores for seven months of this year as per official returns, in long tons:

	Spelter.		Zinc ores.	
	1915.	1914.	1915.	1914.
July	5,340	140	none	1,319
Previously reported ...	57,471	690	605	7,180
Total for 7 months....	62,811	830	605	8,499

LEAD

The market has been dull, but prices have been well sustained, the A. S. & R. Co. continuing to quote 4.50c., New York. London has been more active than New York, largely because of buying for shipment to Russia by way of Archangel before the close of navigation. Following this demand, when a high point of £25 2s.6d. was reached (October 1), London eased off again, and was quoted on October 6 at £23 7s.6d. The New York quotations followed the trend at London both ways. The lead market in general is regarded as in a sound condition, and despite the recent quiet, the wonder is that the leading interest has not advanced its prices. The exports in the first seven days of October totaled 340 tons.

TIN

Except for occasional spurts of buying, the tin maket has been extremely dull, and the tendency of prices has been downward. On October 4 and 5 business was done at 32c., or a shade lower. On October 6 London advanced £3 and the New York quotation went up 1c. Early this week the trade was greatly concerned, and prices were stiffened by a rumor that Great Britain was contemplating the imposition of a 10% export duty, similar to the 2½% duty it recently placed without warning on rubber. London was immediately cabled for information, but the replies received disclaimed all knowledge of the rumored duty. Such a tax, of course, would be paid by the consumer. The statistics for September showed that the total visible supply on September 30 was 15,191 tons, against 15,127 tons, August 30, and 14,613 tons, September 30, 1914. The deliveries and stocks were mentioned last week. Arrivals at Pacific ports destined for the East in September amounted to 500 tons. The total deliveries this year aggregated 35,675 tons, which is 2175 tons over those of the same period last year. There was afloat October 7, 5235 tons.

BOOK REVIEWS

Practical Geology and Mineralogy. Revised edition. By W. D. Hammon. P. 253. Ill., index. The Way Press, South Pasadena, California 1915. For sale by the Mining and Scientific Press. Price, $2.50.

This work, which is in its second edition, is suitable for students in geology and mineralogy, being somewhat elementary in form. The fundamentals of geology, petrology, mineralogy, and mineral deposits are described in simple language, accompanied by illustrations.

The Mining World Index of Current Literature. First half of 1915. By Geo. E. Sisley. P. 208, with authors' and subject indexes. Mining World Co., Chicago, 1915. For sale by the Mining and Scientific Press. Price, $2.

This publication is so regular and arranged on similar lines to previous editions, that there is nothing new to be said about it. As a reference book on technical articles published throughout the world it will be found valuable to editors, libraries, mining and metallurgical firms, and to those who find it necessary to consult the varied subjects discussed.

Surveying Manual. By William D. Pence and Milo S. Ketchum. P. 384. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by *Mining and Scientific Press*, San Francisco. Price, $2.

This is the fourth edition of this useful manual. The book has been thoroughly revised and considerable new matter included. The general object of surveying, the use of instruments, methods, etc., occupies most of the volume. Public-land surveying and the retracement of old lines is then discussed. The next chapter treats very briefly of railroad surveying, circular railroad curves being merely mentioned and spirals not even that. It is evident, however, that the authors expected some other text-book to be used for this branch of the work. Other chapters treat of probable error, methods of computing, and topographic drawing. The usual mathematical tables are included. This edition, as well as those that have preceded it, will be of great value as a student's text-book, and to some engineers as a reference pocket-book as well.

Conservation of Water by Storage. By George F. Swain. P. 369. Ill., index. Yale University Press, New Haven, Connecticut. For sale by *Mining and Scientific Press*, San Francisco. Price, $3.

This volume is based on lectures delivered before the Sheffield Scientific School. The first chapter deals with the well-known but generally disregarded facts concerning waste and conservation of natural resources. After pointing out that while there is little or no absolute loss in allowing most natural resources to remain unused for a time, undeveloped water-power, on the other hand, is a total loss for the time being, the author discusses the laws relating to the use of water, particularly water for power-purposes. The doctrine of riparian rights and its modified application in many States is considered. The regulations of the Federal Government regarding water-power development at Government dams, at private dams, and on the public domain are discussed. The author holds that while the imposition of a tax on the private power-companies on the basis of power developed may be inadvisable, still such provisions have been but a slight hindrance to development as compared with the uncertainty of tenure for all projects dependent on the Federal Government for approval. The chapter on Technical Aspects of Conservation by Storage deals mainly with run-off data and with the construction of dams. Two chapters are devoted to Forests and Stream-Flow and to Floods and general means for their prevention or mitigation. The appendix contains several legal documents pertaining to the question of water-power development and a bibliography.

RECENT PUBLICATIONS

U. S. Geological Survey, Washington, D. C., 1915:

Tin Mining in Alaska. By Henry M. Eakin. Bulletin 622-B. P. 14. Maps.

Production of Bauxite and Aluminum in 1914. By W. C. Phalen. P. 27.

Production of Borax in 1914. By Charles G. Yale and Hoyt S. Gale. P. 16.

Production of Salt, Bromine, and Calcium Chloride in 1914. By W. C. Phalen. P. 16.

Mining in the Juneau Region, Alaska. By Henry M. Eakin. Bulletin 622-C. P. 8.

Some Cinnabar Deposits in Western Nevada. By Adolph Knopf. Bulletin 620-D. P. 10.

Gold Deposits near Quartzite, Arizona. By Edward L. Jones, Jr. Bulletin 620-C. P. 13. Map.

A Reconnaissance in Palo Pinto County, Texas. By Carroll H. Wegemann. Bulletin 621-E. P. 9. Illustrated.

Mining in the Fairbanks and Hot Springs Districts, Alaska. Papers by Henry M. Eakin. Bulletin 622-G. P. 17.

Mineral Resources of the Chisana-White River District, Alaska. By Stephen R. Capps. Bulletin 622-F. P. 39. Map.

Gold, Silver Copper, and Lead in South Dakota and Wyoming in 1914. Mines report. By Charles W. Henderson. P. 16.

Possibilities of Oil in the Porcupine Dome, Rosebud County, Montana. By C. F. Bowen. Bulletin 621-F. P. 10. Maps.

The Healdton Oil Field, Carter County, Oklahoma. By C. H. Wegemann and K. C. Heald. Bulletin 621-B. P. 30. Ill., maps, charts.

Iron-Ore Deposits Near Nome, and Placer Mining in Seward Peninsula, Alaska. Papers by Henry M. Eakin. Bulletin 622-I. P. 13.

The Fractional Precipitation of Some Ore-Forming Compounds at Moderate Temperatures. By Roger C. Wells. Bulletin 609. P. 46. Illustrated.

Mining on Prince William Sound, and the Gold and Copper Deposits of the Port Valdez District, Alaska. By B. L. Johnson. Bulletin 622-E. P. 58. Maps.

Equipment for Current-Meter Gaging Stations. By G. J. Lyon. *Water-Supply Paper* 371. P. 64. Ill., plans, index. This is a valuable work for hydraulic engineers.

Relation of the Cretaceous Formations to the Rocky Mountains in Colorado and New Mexico. By Willis T. Lee. *Professional Paper* 95-C. P. 32. Illustrated.

Guidebook of the Western United States. Part A. The Northern Pacific Route, with a side trip to Yellowstone Park. By Marius R. Campbell and others. Bulletin 611. P. 212. Ill., maps, index. Part C. The Santa Fe Route. With a side trip to the Grand Canyon of the Colorado. By N. H. Darton and others. Bulletin 613. P. 194. Ill., maps, index.

The Mexican Oil Fields. By L. G. Huntley. P. 41. Illustrated. Reprint from *Transactions* of the American Institute of Mining Engineers. An abstract will appear in another issue of the Press.

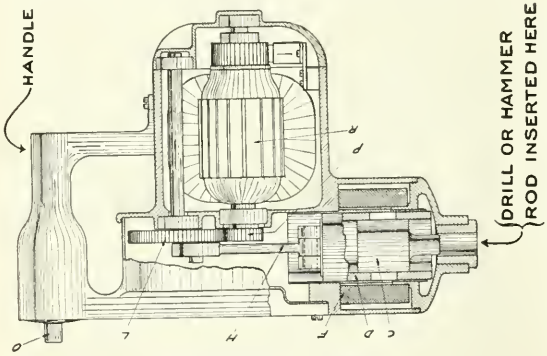
Radium in the Light of Recent Discovery. By Paul Börnsen. P. 36. Published by the author, 301 Tennessee avenue N.E., Washington, D. C., 1915. A presentation of new facts and problems.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Operation of the Western Electric Hammer

The principle on which this hammer works is as simple as it is clever and effective. The principal parts are a motor, a drill or hammer, and a magnetic clutch-plunger interposed between the two. Connected to the motor *R*, through hardened gears *P-L* and connecting rod *H*, there is a cylindrical sleeve *D*, having two relatively thick end sections joined together by a thin centre section. This latter is as thin as is consistent with mechanical strength. The plunger *C*, which delivers the blow to the drill, lies loosely within this cylinder,



THE NEW ELECTRIC HAMMER.

and is not mechanically connected to any part of the mechanism. Outside of the sleeve is the magnet-coil *F*. This is stationary, the sleeve moving back and forth within it. The coil is in series with the motor and the current in it is always in the same direction and steady. As soon as the circuit is switched on, which is done by a button *O*, conveniently arranged on the handle, the solenoid creates a magnetic circuit, with the thick sections of the sleeve as the poles and the plunger as the armature. As the sleeve is moved back and forth by the motor the effect is that of moving the pole-faces of the magnet back and forth, and the plunger clutched across the poles moves with it, transferring its energy to the drill when it meets it, which it does near the end of the stroke. The plunger is slightly longer than the thin section of the sleeve, which gives it a certain amount of over-travel and an elasticity of connection, which entirely removes the strain and jar of the blow from the machine. The motor is series wound, and the gears are of oil-hardened special gear-steel. Ball-bearings are used throughout.

Commercial Paragraphs

The Krogh Manufacturing Co., of San Francisco, recently sold 40 centrifugal pumps to the Anaconda Copper Mining Co., Montana.

The Fall number of the *Yuba Bulletin*, published by the Yuba Construction Co., Marysville, California, contains notes on the Yuba ball-tread tractor and Yuba dredges.

The Burd High Compression Ring Co. of Rockford, Illinois, announces the appointment of Robert Allan, as district branch manager for Northern California. Mr. Allan was formerly attached to the Dallas, Texas, office. His headquarters will be at San Francisco, where he has taken offices and will carry a complete stock, at 847 Phelan building.

W. E. Hardy, for the past eleven years connected with the Diamond Rubber Co., and the B. F. Goodrich Co., and lately in charge of the sales of its mechanical rubber goods division, has recently been apointed sales manager of the Boston Belting Co., Boston, Massachusetts, manufacturers of mechanical rubber goods.

On October 1 the property and business of E. I. du Pont de Nemours Powder Co., of New Jersey, was sold and transferred to E. J. du Pont de Nemours & Co., of Delaware, a corporation organized for the purpose of taking over and carrying on the business. Capital stock amounting to $120,000,000 will be issued. The new name is the same as the original, established in 1802. Chemicals are made as well as explosives.

The Lunkenheimer Co.'s exhibits at the Expositions at San Francisco and San Diego have been described in the Press. The firm reports that the jury of awards was impressed with the quality of the engineering appliances displayed and granted the medal of honor at the Panama-Pacific Exposition, and the grand prize at the Panama-California Exposition. The company has its executive offices and factories in Cincinnati, Ohio, and maintains numerous branch offices and selling agencies throughout the United States and foreign countries.

On February 15, 1906, the California Hawaiian Sugar Refining Co. installed a 36-in. 7-ply Goodrich conveyor-belt. Since then it has caught and carried 2,000,000,000 lb. of sugar that had dropped four feet in 125-lb. lumps, before any radical wear was noticeable. In August 1915 the B. F. Goodrich Co. received an order for another belt. It is 1443 ft. long, 36 in. wide, and weighs 11,983 lb. This belt will receive similar severe working strains as the first one.

The Bucyrus Company announces the appointment of the Union Construction Co., San Francisco, as its agents for the sale of placer dredges for use in Western United States, Western Canada, and Alaska. The Bucyrus Co. states that it has supplied more placer dredges than any other manufacturer, and the Union Construction Co. has had wide experience in the building of hulls and in the erection of such machines in the United States, Alaska, and foreign countries. Estimates will be given for machines of either the standard revolving-screen or the small light-flume type.

An eight-page pamphlet entitled 'Oil Flotation—Oliver Filtration' has been issued by the Oliver Continuous Filter Co., San Francisco. The principle of flotation is briefly described, and as the concentrate is difficult to handle an Oliver filter is recommended to be used for de-watering. A number of these machines are used at the Anaconda and Inspiration flotation plants. Three cents per ton will cover the full cost of de-watering flotation concentrate, including interest, depreciation, and amortization. Plans and short descriptions are given of the filters. The filter was awarded a medal of honor at the Panama-Pacific Exposition.

A leaflet issued by the Nordburg Manufacturing Co., Milwaukee, Wisconsin, illustrates recent installations of its electric hoists, one page showing seven important details of construction. Large copper companies have recently purchased electric hoists from this firm.

EDITORIAL

T. A. RICKARD - Editor

DURING the first year of this War the people of the United States bought 660,000 motor-cars worth $500,000,000, or as much as the Anglo-French loan.

AT the present time the United States is like an unarmed man whose house is full of gold and food, while across the road a number of heavily armed gentlemen, in need of both gold and food, are engaged in a fight, from which one or other, needing much gold and more food, must eventually emerge victorious.

PROTESTS are being made in London against a possible tax on gold-mining profits. It does seem unwise to discourage the production of the necessary metal. We note also that a point is made of the fact that such profit is mainly a return of capital. Of course, it is; but before the tax-gatherer will accept the idea, those engaged in mining must believe it, and give proof of that belief.

AMONG the factors helping the copper market is the entire elimination of Australian metal, of which 11,000,000 pounds was imported into this country, for refining, last year and 14,000,000 pounds two years ago. Similarly the Mexican imports, which amounted to 40,000,000 pounds last year and 60,000,000 the year before have dwindled to 2,000,000 pounds during the first seven months of the current year.

GEOLOGY finds an honored place in our pages, when it does not disdain to be of practical service to the miner. In this issue we publish a valuable contribution on the geology of the Shasta copper region by Mr. Oscar H. Hershey, together with a map made by him to show the distribution of the ore-bearing rocks. We feel assured that this information can be applied to useful purpose by those engaged in mining.

RECENTLY we referred to the earth tremors or 'air-blasts' in deep mine-workings under a heavy overhang. On September 28 the Village Main Reef mine in the Transvaal was the scene of an unusually violent collapse of heavy ground, 3 natives being killed and 27 injured. If the accident had happened half an hour earlier hundreds of workers would have been killed. The dispatch says that the continued recurrence of tremors is causing anxiety in the vicinity.

LODE MINING in the interior of Alaska, as distinguished from the south-eastern coastal region, has been a big disappointment, but we hear news of promising finds in the Port Wells district, between Valdez and Seward, near the coast and north-westward from Juneau. The gold is found free in small quartz veins. Good results were obtained during the past season. We hear also of gold-quartz discoveries in the Willow Creek district, on the eastern side of Cook Inlet. Three promising mines are at work and other prospects are in course of development.

WORKERS in flotation will be grateful to Mr. Oliver C. Ralston for his suggestive article, and particularly for the avowed intention with which it is contributed, namely, the desire to help others in the work of research. That is just what is most needed at the present time, when the wide-spread desire to apply the process has outrun the technical information required to understand the physics of the operation. The laboratory of the Bureau of Mines at Salt Lake City is doing much useful work, setting an example that others will do well to follow.

NATURE laughs at us sardonically from time to time. Just when San Francisco is at the height of its celebration of the completion of the Panama Canal a slide of 10,000,000 cubic feet of rock blockades the new waterway that had been open long enough to prove its great service to mankind. The engineers appear to have made up their minds to accept the inevitable and allow the ground to slide into the Canal until the angle of repose has been restored. Unfortunately, the stoppage comes just before the annual movement of grain, but fortunately it comes at a time when the military use of the Canal is in abeyance.

ON October 19 the Government of the United States, supported by six of the South American governments, notified the representative of General Venustiano Carranza that the administration of which he is the chief executive is recognized henceforth as the *de facto* Government of Mexico. At the same time it was intimated that a diplomatic representative will be accredited shortly by the United States to Mexico. This event was marked by an entire absence of ceremony, but it lost none of its importance thereby. After nearly three years the two neighboring countries resume polite relations, and the Government of Mexico is accepted again in the comity of nations. We presume that this formal act will be followed by the placing of an embargo on the export of munitions to any Mexican faction remaining insurgent and that concurrently the sale of cattle and corn stolen by such insurgents will be stopped by the joint action of the two Governments. When this is done,

the ability of Villa and Zapata to continue in effective revolt will be taken from them. We expect a rapid disintegration of such remaining insurgent forces and a general acceptance of the Carranza régime. Señor Elisio Arredondo, Carranza's personal representative at Washington, has stated that "foreign capital will be welcomed" and a decree of amnesty will be promulgated at an early date. That presages a revival of mining activity and a resumption of smelting operations. For a while the lingering brigandage will hinder work in the outlying districts, but at the chief mining centres there should be but little delay in the re-opening of idle mines. The principal hindrance will be the condition of the railways, most of which have been 'shot to pieces' as the tide of civil warfare has advanced and receded. The railway from Vera Cruz to Mexico City appears to be intact, and the main line from El Paso to the capital should be placed in working order with as little delay as possible. That is the first step to the complete pacification of the country. On the whole, we consider the outlook more promising than at any time since February 1913.

FLOTATION is making good progress at Butte, not to mention its neighbor Anaconda. In addition to the Butte & Superior and Elm Orlu plants, treating zinc ore, there is to be a third flotation mill, at the East Butte mine, to concentrate copper ore. At the Butte & Superior the quality of the work continues to improve, the zinc content of the concentrate increasing from 50.27% in September 1913 to 53.61% in September 1914 and 55.92% in September of this year. Concurrently the recovery has improved, being 90.09, 89.69, and 92.79% successively in the corresponding month of each of the three years. The Butte & Superior is now obtaining 13,000,000 pounds of spelter from 41,000 tons of ore per month. We shall be enabled shortly to publish additional information concerning metallurgical improvements at the Anaconda, where something new and something worth-while is continually being developed to practical success.

Prospect and Retrospect

War, on a big scale, between great organized industrial communities, is catastrophic not only in its sacrifice of life and property among the belligerents, but in its sudden choking of avenues of commerce in one direction while opening new opportunities in another. A 'drive' in Flanders that wastes three million shells costing $18 apiece means a consumption of material and labor that provokes scanty remark only because the loss of life transcends it so greatly in significance. The floating of a $500,000,000 loan as an underlying lien on two great peoples is impressive, but the corollary to such a borrowing is apt to be pushed into the background, namely, the taxation that it imposes upon the productive energies of millions of Europeans in the years to come. In these days we take short views of life, our mental perspective has been shattered, we have learned from a single year's experience that the unexpected readily merges into the probable. A year ago New York, as a representative of the financial and industrial energies of the whole country, was in a state of acute depression; nobody foresaw that within so short a time the logic of events would make that city the chief financial centre of the world, for a time, at least. Suddenly the United States found itself grasping a commercial supremacy beyond the dreams of the most sanguine. By a great stroke of luck the opportunity came just after the Federal Reserve Act had organized the banking credit of the nation on a sound basis. Thus the issuance of international credits passed from London to New York. Coincidently the clearing of the Atlantic trade-routes by one of the belligerents guaranteed the big ferry-service required for the continued transfer of manufactured products and food-stuffs from our continental territory to the markets still accessible in Europe. A realization of the immensity of the consumption of munitions caused an enormous trade in such material to develop almost overnight, galvanizing the beneficiaries of it into herculean efforts to furnish an adequate supply. Early this spring a guess was made that $1,000,000,000 would be spent by the belligerents, chiefly the Allies, on purchases of munitions, food-stuffs, and supplies generally, to be exported from this country during the current year. This is known now to have been a low estimate. Meanwhile the mining industry, which supplies the metals required in the wasteful game of war, has revived in a manner wholly unexpected in the first months of the fighting. Mines that had been shut-down in response to idle markets, productive activity that was paralyzed by the uncertainties of the moment, and exploratory work that seemed futile during the early period of the Great Calamity alike were re-vitalized as soon as it became apparent that mining was destined to be signally stimulated by the requirements of world-wide warfare. The exploitation of copper ores, of course, profited by the demand for brass in a thousand forms, but the concurrent consumption of zinc had the more striking effect, causing the price of spelter to be trebled and even quadrupled, thereby turning relatively poor mines into veritable bonanzas. But this effect is now becoming widely distributed, from the chief metals it has spread to secondary mineral products like manganese, magnesite, tungsten, and molybdenite; indeed, there is scarcely any product of the mine in this country, at least, that has not risen rapidly in value by reason either of a greater consumption or a closing of foreign sources of supply. The consequence, naturally, is to expand the operation of existing mines, to promote the re-opening of old or abandoned properties, and to stimulate search for new ore deposits. As yet, the full effect is restricted by feelings of restraint and prudence, due to doubt regarding the persistence of present conditions. Assuredly we hope that they will not last, as far as concerns the diversion of the metals from peaceful consumption to the assistance of organized murder, but beyond the abnormalities of the immediate present we see the times of reconstruction and rehabilitation in which the metals will be required, not only as before, but more than ever before,

in the making of the wires of communication, the machinery of manufacture, the vehicles of transport, the roofing over new homes, and the domestic utensils required by the devastated regions of Europe.

Labor Troubles

Strikes are called 'labor troubles,' meaning that they are troubles caused by labor, yet they are quite as much capital troubles, whether we think them caused by, or only directed against, capital. It depends upon the point of view. That explains why most people escape the dilemma and impute the evil of unrest to agitators or anarchists, to autocrats or to tyrants, and thus discharge their responsibility by an epithet. The strike at the copper mines in Arizona and the visit of the younger John D. Rockefeller to the coal mines in Colorado have brought the subject to the front again, only a few weeks since the last Labor Commission closed its activities in the eruptive efforts of Mr. Frank P. Walsh, like a volcano that emits clouds of smoke and streams of mud ere it is extinguished. These labor disturbances have much in common. The strike that began at the copper mines of Michigan in July 1913 affected 14,300 men. It was made on the initiative of the Western Federation of Miners, previously responsible for the murders and assassinations that brought infamy upon the Coeur d'Alene, Cripple Creek, and Telluride districts twelve to twenty years ago. The mining companies were requested peremptorily to appoint representatives to meet this gang for the purpose of adjusting sundry grievances, of which it may be said that some were real, others unreal, and all subordinate to the necessity for refusing to deal with an organization so anti-social as that led by Charles F. Moyer. The usual lawlessness and aimless bloodshed were followed by a farcical governmental investigation, during which the strike petered out. But not before two good results had ensued: the concession of an 8-hour day was confirmed and it was proved that the Lake Superior copper region could not be terrorized by a band of conspirators from the outside.

Then came the strike at the coal mines of the Colorado Fuel & Iron Company in September 1913. That affected 11,700 men. The question at issue was the recognition of the United Mine Workers of America, an organization previously of good repute, but a national organization, and for that reason anathema to the mine management, which declined to deal with any but its own employees and refused to recognize those who, it claimed, had intimidated peaceful workers into antagonism against the company. A concentrated form of civil war ensued, with brutalities unspeakable; many were killed, the State militia proved incapable, the Governor had to call upon the President to send Federal troops, and order was restored finally in the wake of exhaustion. Later came the Government investigation under the chairmanship of Mr. Walsh, who used the opportunity to win notoriety by advocating a gospel of confiscation and stultifying the system of inquiry by commission. In the sequel, like a vaudeville after a melodrama, we have the visit of Mr. Rockefeller to the mines, with its belated effort to learn something about the big business for which he is responsible and the proposal of a scheme for joint conferences between representatives of the men and the company.

While Mr. Rockefeller is going through the motions of devising a scheme that will kill the union, another strike is in progress in the Clifton-Morenci district of Arizona, where 5000 men are now idle. This also involves the old issue of the Western Federation with Moyer as president, plus the further complication that the majority of the laborers are Mexicans. Owing to the narrow margin of profit derived from the exploitation of these particular mines, it has been found expedient to employ a cheap class of alien labor—Mexican, Italian, and Spanish. The relatively low wage-scale has given the Western Federation a lever whereby to cause an industrial upheaval. As in Michigan, two years ago, the managers have refused any dealings with the agents of the Western Federation, the mines have been shut down, and the usual methods of terrorism are being applied. The State militia is unable to overawe the disorderly elements, the Governor makes speeches calculated not to injure his political aspirations, and the Federal power is besought to come to the rescue. Meanwhile the protection given to the community is so uncertain that the managers of the three mines have gone to El Paso, in another State, explaining that their presence on the scene of conflict might serve as an incitement to riot, from which the Governor's words and actions furnish no hope of proper protection.

Here it is proper to remark that troubles of this kind are not restricted to any one region or any particular country. At the time when the Michigan strike was in progress, a similar disturbance—but of a more violent description—broke out on the Rand, among the 23,000 white workmen employed at the big gold mines of the Transvaal. This strike hinged on the refusal of the companies to recognize any union outside that of their own employees, but, after a riot, in which many were killed and all sorts of savagery ensued, the Government sent regular troops to restore order and insisted on fair play in the adjustment of grievances. The result was that the mining companies had to recognize the Miners Association of the Transvaal, but not the wider Federation of Trades, which had threatened to involve all South Africa in a comprehensive strike. That Federation was dominated by a lot of irresponsible hot-heads like its examplar in this country. It was a question not so much of collective bargaining, of the rights of capital and labor, of adjusting hours and wages; it was, and is today in Arizona, the question whether a Mafia or a Black Hand is to terrorize legitimate industry. In Michigan, in Arizona, in South Africa the bitterness of the struggle arose chiefly from the fact that the mine managements refused to recognize an organization that was less of a trade-union than a combination of professional agitators. And because that is the issue we can-

not expect a reasonable discussion of the relations of employer to employee. The anti-social anarchist must be eliminated before social arrangements can be made matters of friendly disputation. That or some other extraneous factor is always tending to prevent a dispassionate weighing of the merits of the case in these industrial misfits and misunderstandings. Yet no real cure of a chronic ill is possible until an unprejudiced diagnosis has been made. We shall return to the subject in our next issue.

Psychology of Advertising

On another page we publish a short article on this phase of journalism. It will call for no apology if it should interest our readers. We believe it will. In the first place, the reader should be aware that it is to the advertising that he owes indirectly his reading matter; the subscription to this paper, for example, barely pays one-third of the mechanical expense involved in the work of publication. Nevertheless it is the reader, not the advertiser, that the editor endeavors to please by the matter he offers in the form of critical and descriptive writings. The advertiser need not read the paper, it is not necessary that he should be interested in that way, but it is vital that the paper should interest the man who buys the machinery or supplies offered for sale by the manufacturer through the medium of advertisement; for until the reader has found something worth reading he is unlikely to look at the advertising annex. That is a fact of which most of us are well aware. If we read one article only in a magazine, we lay it aside without looking at the advertising pages, but if we hold it in our hands long enough to read more than one article we are pretty sure to continue holding it while we turn over the advertising pages. Then the manufacturer is given a chance to deliver his message, which is an offer to sell something that he makes. The chance being given, by the attractiveness of the reading pages, it remains for the manufacturer to present his advertisement so that it will command attention. He does not always succeed. Sometimes it is his fault; sometimes that of the reader. On the whole the latter must be absolved, if of average intelligence, for he is the one that ought to be suited. Fortunately the men that buy machinery are not slow-witted; they are men of trained intelligence and keen insight. Therefore the advertiser can afford to address them as if they were his equals mentally. Most blunders in advertising arise from a failure to appreciate this simple fact. To be convincing, one must be sincere. To impress another man it is necessary to employ the language he can comprehend. That is the rule of all effective writing: remember the reader. Unfortunately for the advertiser, the proprieties prevent an editor from preparing the advertisements, otherwise it might seem well for him to supervise both parts, the reading and the advertising, of the paper, since both are prepared for the edification of the same persons. What a time the poor editor would have in preparing advertisements for rival firms, to be equally serviceable and yet differently worded, to be competitive yet not mutually contradictory, as competitive claims sometimes are! We have heard that this has been tried, with humorous results. But we prefer to dismiss the nightmare thought, passing to consider other aspects of this delicate—and therefore interesting—problem. In order that the subscriber, the man engaged in the business of mining, may look at the advertisements, he must first be persuaded to look at the reading pages; therefore the reading matter must be interesting; and to be that, it must be honest; in short, the reader must be able to trust the editor not to abuse his confidence. Hence the reading matter must not emanate from the advertiser, it must not be modified or influenced in any way by him, it must be entirely independent of him, both in fact and appearance. The body of the paper must be prepared with the sole idea of interesting, that is, assisting and informing, the men in charge of mining and metallurgical operations. On the other hand, the advertising pages should be prepared with a view to holding and continuing that interest so that their message may lead to business, now or in the near future. Hence the advertiser ought to study the reading pages and learn from them what kind of language to talk: how to approach his putative customer. To send the same advertisement with the same wording in its appeal to papers commanding diverse clienteles is not wise. An announcement in the *Ladies' Home Journal* should be couched in phraseology different from that used in the Mining and Scientific Press. Heart-to-heart talks on pillow-shams will not move a hard-headed engineer, nor will the terse technical terms of a manufacturer strike home in the heart of a gentle schoolteacher. The editor, and his co-workers, the contributors of articles, may make mistakes—being human, that is inevitable—but they must play square, they must not attempt to deceive the reader with 'write-ups,' 'reading-notices,' or any other simulacra of technical information prepared by the advertiser as a means of obtaining gratuitous publicity in an underhand way. The advertiser who persuades the editor to publish such stuff should ask the business manager for a 25% discount on his bill, for the publication of it has the effect at once of spoiling the effectiveness of the advertising by causing possible customers to cease reading the paper. In short, the safety of a professional paper, such as this, must depend upon a water-tight compartment between the editorial and the business offices: not a line of reading matter should be purchasable, not the fraction of an advertising page should be gratuitous. After all, it is a clean-cut business; it affords an example, none too common, of honesty being the best policy, of square dealing being the most profitable. If we can hold the attention and confidence of the mining and metallurgical profession, the business men, the superintendents, and the foremen engaged in the daily work of mining, we shall not need to fear the result. The paper that commands the trust of the profession will win the support of the trade.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Engineer as a Mine Operator

The Editor:

Sir—The question is frequently asked: Why do not more of the competent mining engineers, now apparently content to hold subordinate positions with large mining corporations, in which there is little opportunity to show their full ability, and where individuality is sometimes destroyed, identify themselves with new development enterprises? The risk is, of course, greater, but the chances for success on a large scale are more promising.

I notice that some prospectors go so far as to intimate that the engineer is in a class with the fortune-teller, who takes the public money for giving information, but does not think enough of his own judgment to put it to the test. Every field-geologist knows that on this terrestrial foot-stool there still remain many virgin fields of promise.

We all know that the paramount weakness of the many newly organized so-called development companies is mining brains. Why then, asks the uninitiated, does not the engineer avail himself of the opportunities presented by this form of enterprise and become immediately a big frog in a small but expanding puddle?

Most of us, I think, before losing hope, have tried the above plan in one or more of its many forms. As one who has tried strenuously this shorter road to gain and glory, I shall tell what to me is the most discouraging aspect: the insupportable incubus, the Nemesis who pursues, the Old Man of the Sea who rides, the Albatross which hangs round the neck of the pioneering engineer. To my mind, it is the irreconcilable difference in the business ideas and ideals of the mining engineer, and the type of promoter usually found with, and supposedly necessary to new mining enterprises. I do not refer to the great promoters who father mighty enterprises, because they are men of great ability, knowledge of the business to be undertaken, personality, foresight, and faith. Without such men there could be little advance made in any line of endeavor. Nor is reference made to the fly-by-night scoundrel who is a plain thief. The man who has put gray hairs before their time among the red ones on the writer's dome is the promoter, usually honest within certain limits, but whose training as a salesman has taught him that the proper procedure with the prospective investor, is, by hot-air applications etc., to so enthuse, blind, bewilder, and befuddle him with visions of immediate wealth, that Mr. Investor's involuntary grip on his judgment slips a cog, and before he regains himself is in for a few hundred or a thousand dollars.

After No. 1 has been properly hooked and the loose change shaken out of his pockets, the plan is to rush joyously on to the next victim. A promoter once said to me: "If I don't get a man the first time, I never go to see him again."

Of course, the engineer, by inclination, training, and tradition of the Elders is a man who thinks along straight lines. Everything is either a fact or a fallacy to him. Fuss and fiction disturb and disgust him. Because he has the imagination of a builder, a good clean promising prospect is the most alluring object in the world to him. He studies this prospect from every angle within his experience, and finally decides that with proper development his little acorn may become an oak some day. He prepares a careful, conservative, truthful report of the property under examination, turns it over to the financing genius who frequently is also president, general manager, major domo in chief of the company, and he scans this report with but one thought, and that is to learn the 'talking points' of the proposition. And should these 'talking points' be not sufficiently emphasized, the report is returned to its author with some helpful suggestions for its betterment. To the promoter the only good report is one which shows the chances for loss to be minus zero, with chances for success infinity plus, a report which, like the moon, presents but one side, and that the shining one.

Sometimes the promoter tries, if the engineer is at a sufficient distance, to improve the report himself. Here are a few instances in the writer's personal experience. In the sentence "The Bull Whale property has considerable young timber suitable for lagging purposes," the word 'lagging' was changed to 'logging.' In the sentence "The Pipe-Dream vein is not extensively faulted as previously supposed," the word 'extensively' was omitted in the printed circular.

A promoter once asked me if true fissure veins did not always increase in volume and value with depth. I told him that was not my experience, and asked who had given him such an idea. He named R——, a notorious charlatan, whom he said had told him that these metaliferous masses were intruded in a molten state from abyssmal depths, and that during the cooling process, by reason of their specific gravity, the heavier metals gravitated downward. For that reason a uniform increase in values was to be expected, especially in the very heavy metals, such as gold. This seeker for information then wanted to know my 'theory.' I gave him an elementary lecture on ore deposition, at the conclusion of which he

exclaimed: "Then the ore don't always go down?" Unfortunately, no. His reply was "Your theory ain't worth a damn to sell stock on. I'll stick to R——'s."

The promoter usually trys to start off his proposition with a blare of trumpets, and after the initial frenzy to keep up the fever with inflammatory telegrams, and flamboyant letters. And if the engineer at the mine is an honest man and tells the promoter of a nice warm place where he may spend his winters, the promoter is not subdued, but simply comes from some other angle. In fact, invective may be used upon him, until it becomes trite, to no avail. And the usual result is that the engineer quits in disgust, or a fight is developed which usually ruins the enterprise.

The fault is not all the promoter's, for a sufficient number of engineers have lent themselves to the abominable buffoonery and chicanery of the professional stock juggler to warrant the hope that others may develop a yellow streak. And by their chimerical statements they have cast discredit upon the profession. The deserter always makes it harder for the man who stands by his guns.

Another fault of engineers, and one to which the writer confesses is that we spend too much time away from the centres of capital. We give too little thought to financing problems. Most of us could and do inspire confidence and trust in those who know us. But we do not know how to reach the man who could, with one stroke of his magic wand, transform our little acorn into the great oak of our dreams.

CLYDE M. BECKER.

Flotation in Australia

The Editor:

Sir—We have just read the article on 'Flotation in Australia,' by Charles S. Galbraith, published in your journal issued on the 17th of July last.

The statements made by Mr. Galbraith in relation to Mr. A. de Bavay, the inventor of the process used by this company, are quite inaccurate. Mr. Galbraith was appointed manager of the company's experimental works on December 18, 1906, and was in the employment of the company until March 7, 1907, about three months. This fact speaks for itself.

Mr. Galbraith states that Mr. de Bavay is a Frenchman. That is not so; Mr. de Bavay is a Belgian. The exposition of Mr. de Bavay's views in regard to the agency of flotation and the way his discovery was made are absolutely incorrect. Mr. de Bavay perfected his invention from the initial to the present stage without any assistance—certainly Mr. Galbraith was not of any assistance to him.

Mr. Galbraith states "that it was only when the inventor was put aside and the management allowed to get to work that success was achieved." This is absolutely untrue. Mr. de Bavay has not only the honor of being the inventor of the process which bears his name, but he developed it to a successful commercial issue.

Since this company started operations, 2,562,000 tons of zinc tailing has been treated for the production of 730,000 tons of concentrate, averaging 49% zinc, 6% lead, and 9 oz. silver per ton, and £475,000 has been distributed in dividends to the shareholders.

We trust that, in justice to Mr. de Bavay, you will give this refutation of Galbraith's statements a prominent space in your paper.

EDWARD H. SHACKELL,

Secretary, Amalgamated Zinc (De Bavay's), Ltd.

Melbourne, September 22.

Efficiency Engineering in Mines

The Editor:

Sir—I have read with considerable interest Mr. P. B. McDonald's letter in your issue of September 4. Kindly allow me to make a few remarks on this subject myself.

Efficiency engineering as applied to mining is, at present, in what might be called its embryo stage, and any examples which may be cited against scientific management should not be taken as final in order to condemn its introduction into the mining industry. A careful study of such failures will usually bring out the fact that the system which was being introduced was not the true Taylor system, but an unscientific modification made by the man in charge. The Taylor system does not advocate "spying" on the men, therefore we cannot consider as an example of the failure of scientific management in mining that mine in Michigan where attempts at 'Taylorism' were made, as was stated by Mr. McDonald.

As is the case with mining now, so it was in the manufacturing industries ten or twelve years ago—a great deal of opposition existed on the part of the workers. That this opposition has greatly decreased where the workers have a clear understanding of what scientific management really means is shown by their preference to work in factories which have adopted the system. That this system creates a greater loyalty between the workers and the management is plainly seen from the opinions of the men in a shop under scientific management. In an article on 'Scientific Management as Viewed from the Workman's Standpoint,' published in *Industrial Engineering*, November 1910, the writer quotes the opinions of some of the workers, and then adds: "Conversation with other men brought out practically the same facts. They are all contented. They took pride in their work, and seemed to be especially proud of the fact that they were employed in the Link-Belt shops."

Any system of management, in order to be successful must have an harmonious co-operation between employer and employee. This co-operation is essential to their highest common interests, and no management can consider itself adequate if it does not try to enter into the mental attitude of its workers. According to Taylor himself, there must exist an "intimate friendly co-operation between the management and the men."

Under scientific management this co-operation on the

part of the workers is the result of, first, the assurance of an increase in wages for an increase in effort; second, the assurance that their health will not be harmed if they follow instructions; third, the personality of the manager or superintendent. In plants operated under the old type of management this co-operation is only dependent on the personality of the manager. A good example of this co-operation or willingness to work, because of the worker's admiration for the general manager, is the case cited by Mr. McDonald of that mining company in New York state.

Scientific management deals directly with the labor problem to a greater extent than any other type of management, consequently an innovation of this kind is, naturally, looked upon with suspicion by the workers. Also, the name has been occasionally, and unfortunately, applied indiscriminately to any sort of system of operation which has not the interests of both the management and the workers at heart, with the result that this suspicion has been greatly increased. It is, therefore, but natural that a good worker under the old type of management should be sensitive to what he is inclined to believe are 'criticisms' by scientific management with regard to him. Only through tactful dealing with the workers can this suspicion and resentfulness be removed and their co-operation assured.

To conclude, scientific management must be introduced by an expert who is able to get along with the men, and can get them to co-operate with him.

Until further studies are made on the application of the Taylor system to mining, we have to content ourselves with the results achieved in the manufacturing industries as to the practicability of the system.

Office Etiquette for Busy Men

The Editor:

Sir—A frequent pose among men who have but little business is to keep a caller sitting in the outside office while the incumbent amuses himself by cutting foreign stamps from envelopes or talking about the last golf-game. The visitor is impressed by the vast amount of business transacted—unless indeed he suspects the truth, that the waiting is done for effect. Much the same end was achieved by a young doctor of our acquaintance who had a friend call him out of church every other Sunday to impress the congregation with the great demand for his services. A little elementary instruction on the treatment of office-callers seems desirable. We suggest that a caller should not be kept waiting more than five minutes. If Jones, who is in his office, is too busy to see Smith within five or ten minutes, he should come out for a moment, greet Smith with extended glad hand and pleasant word, explain that he is busy and send Smith on his way rejoicing, and, if required, make a definite appointment for the next visit. All this should take from twenty seconds to a minute, at longest, and will leave a pleasant impression on Smith's mind; while the cooling of the heels in the anteroom generates hot wrath in the heart. We remember with extreme dissatisfaction, our formal call, some years ago, on the secretary of an important technical society, whose offices are on the Atlantic seaboard. On the other hand, pleasant memories come to mind of a busy financier's kind and friendly explanation of the reasons he was unable to see us. The memory of his few seconds courtesy will never be effaced, while subsequent pleasant visits with the secretary have not yet obliterated the disagreeable impression of the first visit.

San Francisco, September 24.

Accidents in Mines

The Editor:

Sir—In your issue of October 9, I note your article in reference to the discussion of accidents in mines, at the meeting of the American Mining Congress during its session of September 22, wherein you invite discussion of this subject. My experience of thirty years in the management of mines has left no doubt in my mind that most accidents to men underground are due to carelessness of the men. I fully agree with Mr. Day and with you.

Most of the accidents that have happened in the Utica mine were caused by boulders rolling down broken piles of rock where the 'muckers' were shoveling, undermining the piles in search of the smaller broken particles and dodging the boulders that needed breaking with a hammer, leaving them for the next shift.

The men will take all manner of chances at this, including the penalty of being discharged, since we have a strict rule that rock-piles must be kept safe, by picking down from the top and keeping the slope such as will preclude the possibility of boulders rolling down of their own weight. We have discharged men time and again for this, but they persist in taking the risk.

Another breach of care, to be noted almost every day, is their neglect of carefully picking and barring down loose rock after blasting. One would think that any miner would consider personal safety to that extent, but no, there is hardly a day when I am underground that I do not discover one or more examples of such carelessness. I always carry a heavy and long-pointed candlestick, and I often pry down boulders, which had they fallen on anyone, would have caused serious injury, to say the least. And often they require little or no prying. It is no use to fire the guilty parties, because I have found that they are pretty much all alike, and we would have a constant shortage of men. But in flagrant cases, we give them a good 'jacking up.'

Most accidents are due to a spirit of taking chances, miners being a dare-devil lot. Everyone who has had practical experience will agree with me in this. Those who hold otherwise are theorists and of the class of bachelors, male and female, who write such apparently convincing articles on the care and training of children.

Angels Camp, Cal., October 12. F. J. MARTIN.

Psychology of Advertisements

By P. B. McDONALD

A mine-manager is reading a mining weekly; he reads first a well-written and suggestive editorial; then he turns to a special article on a subject in which he is interested, signed by a name that he knows insures lucidity of thought; he next scans a news-letter from a mining centre, and then—then he reads the advertisements! If the subscribers to the mining periodicals did not read the advertisements, the latter would soon cease to be published.

The mine-manager reads two or three advertisements carefully and thoughtfully; they describe products of which he has heard and which he thinks of introducing at his mine. Perhaps they are electric locomotives for underground haulage, or ball-mills, or drill-column hoists, or mine-telephones, or dump-cars, or filters, or rope-drives, or ore-crushers, or conveyors. What the manager is thinking is this: "Will they do our work satisfactorily; I wish I knew more about them; what's the idea of this particular type? for what purpose is that handle? how is regulation effected?" It is true that a note in the corner of the page states that pamphlets or catalogues describing the product will be sent on request. But a mine-manager is a busy man and has but little time to give to each machine with which his mine is equipped. Moreover, his experience with advertising pamphlets has been that they are less understandable than a railroad time-table and such a mixture of haphazard facts mixed with blatant boastings that only a Philadelphia lawyer can distinguish where one begins and the other ends. It is passing strange that a manufacturer who pays for a page of advertising does not use it to tell the readers what they want to know about his product, much as he would do if he were talking to them. Instead, the page is used for printing, in big letters, exaggerated statements of the 'live-wire' variety, full of 'punch,' which mean nothing in particular, and which nobody believes.

After studying two or three advertisements carefully, the mine-manager examines several others hastily. They are advertisements of standard products that need no explanation. Their appearance in the advertising pages is the equivalent of a pleasant meeting with an old friend. Seeing the advertisement every week assures him that the manufacturer is alive, and encourages the feeling that the product is well made; at least that it is not deteriorating.

A certain part of the manager's thinking as he slowly turns the advertising pages is unconscious. He reads the names of the various articles advertised and the addresses of the firms selling them, while sub-concious impressions are being recorded in his brain. The repeated seeing of the advertisements of any particular article will inculcate a belief that the article has merit; and when the time comes to buy, the advertised product will loom up as the sort that is wanted, the superior variety of assured excellence and quality. This is the great silent argument of advertisements, the conception and growth of confidence in the product, the quiet instilling of belief in its usefulness, the feeling that here is worth and satisfaction.

When an article has been advertised steadily and then the advertising is stopped, the thought quietly spreads that the product is declining and that the firm is perhaps losing its position. The former feeling of confidence and optimism in the product becomes replaced by the suggestion that all is not well with the manufacturer, and doubt is manifested as to the ability of the firm. Something appears wrong somewhere, and the goodwill diminishes.

The advertiser in a technical journal should distinguish between the sort of man he is trying to impress and the people for whom articles are advertised in popular magazines. Advertisements in the latter are intended to appeal to a gum-chewing public that knows little and cares less about realities. Mine-officials and engineers, on the other hand, are picked men of unusual keenness and ability, men distinguished from the public that giggles in picture-theatres by years of training, experience, and the consideration of serious problems. An advertisement that might be believed by the readers of a weepy magazine would only awaken amused contempt from a mine-superintendent who has been trained to see things as they are, and who is not at all impressed by 'live-wire' nothings or glorified 'punch.' Yet the ordinary mine-official is constantly on the watch for new machinery and equipment that will save labor or expense, and he is always open to suggestions and arguments that are backed by the logic of facts. He likes to be addressed by the advertiser as if each knew their own business: the serious unpretentious talk of one sensible man to another, not that of a corn-doctor to a passing mob. Mutual confidence is the first requisite to the transaction of business.

MINERAL exports of Peru during the first five months of the current year are as follows, compared with that period of 1914:

Mineral.	1915.	1914.
Antimony	1,315.24	120.14
Bismuth (barilla or concentrate)	210.59	141.27
Copper (barilla or concentrate)	2,036.88	367.72
Silver ore	32.79	35.47
Tin (barilla or concentrate)	17,055.09	18,286.95
Wolfram (barilla or concentrate)	243.34	107.91

The above are in metric tons of 2204 lb. The value of the exports is affected by the lower rate of exchange for the *boliviano*, which is now worth 30c., against 36c. in the early part of 1914.

MINING LITIGATION is an expensive luxury. It is stated that the lawyers' fees in a recent California apex-suit amounted to $60,000. This is a large sum, but the fees of a half a century ago were equally high; for example, Senator William M. Stewart states in his 'Reminiscences' that in four years he received $500,000 fees in the Comstock litigation.

Why Do Minerals Float?

By OLIVER C. RALSTON

*I was very much interested in reading an article by Charles T. Durell, appearing in the PRESS of September 18, under the caption 'Why Is Flotation?' However, I find myself unable to agree with Mr. Durell's line of argument, and for the following reasons:

In the first place I believe that Mr. Durell has used loosely some rather obscure scientific terms which may cause unnecessary confusion to anyone not thoroughly familiar with the physical chemistry involved. The term 'nascent gas' is especially open to criticism. Doubtless Mr. Durell means the dissolved gas that can be liberated from the water, but this is hardly the ordinary sense of the term, and many modern physical chemists will object to the use of the word 'nascent' under any conditions whatever, or even refuse to recognize it, in spite of the old ideas that grew up around it. However, it may be that 'nascent' is a good term to use here in a figurative sense. Another term used by Mr. Durell and to which an objection might be raised is the word 'occlusion' as applied to the gases held by minerals. Mineralogists have long used this term rather loosely, but Mr. Durell does not seem to have taken it up in the same sense. As I understand it, there are three ways other than in visible openings by which gases can be held in solids;[1] these are:

1. In solid solution, in the same way that gases can be held in liquid solutions.

2. In surface adsorption, where the layer of gas immediately in contact with the solid is found to be more or less tightly held by some force of attraction, unnamed, and is hence considerably compressed.

3. In occluded form. This is a term the meaning of which has been much disputed; it is often used in the sense of one or the other of the terms above mentioned. Of late there has been a tendency to call occluded gas any gas that seemingly is held in some manner different from that designated by either of the other two terms, and in a manner not exactly understood. An example is found in certain substances that are known to be finely porous and that seem to hold gases in neither solid solution nor surface adsorption. Charcoal is such a substance. Possibly these have pores of such small diameter that they are of the same order of magnitude as the thickness of the adsorbed layer of gas, so that most of the gas held in them is present in a highly compressed condition. Charcoal absorbs so much CO_2, for instance, that at ordinary temperatures the volume of CO_2 held is enough to fill the known pore-space at a pressure sufficient to liquify it.[2]

There doubtless are very fine openings in our crystalline sulphides, and they admittedly do hold some occluded gas, but good cases of occlusion have been found thus far only in amorphous substances like charcoal, hair, wool, glue, meerschaum, starch, etc. This fact tends to cast a doubt upon Mr. Durell's hypothesis that the occluded gas in the flotative minerals plays an active part in the attachment of gas bubbles to the surface of the mineral.

Another physical fact that casts further doubt on this hypothesis is that occluded gases (and dissolved gases as well) are liberated from the substances occluding them only with difficulty; the last traces of them are still held even when the substance is placed in a high vacuum and heated to a considerable degree. It is as though the molecules of the gas were diffusing out through very small clogged pores. How this tightly-held gas could be liberated fast enough to compare with the exceedingly short time which it takes to accomplish flotation of a sulphide particle, is difficult to explain physically. Mr. Durell has further supposed that there is an osmotic travel of ions from the water solution, in which the ore pulp is made up, directly into the fine openings of the mineral particles. The surface of the particle acts as a septum and at the same time the molecules of the gas diffuse out and join the air from the solution, forming a bubble that floats the mineral. At the present time I cannot see my way to accept Mr. Durell's supposition. Briefly stated, then, Mr. Durell's hypothesis is that "nascent" gas from the water and "dissolved" gas from the solid meet and collect at the surface of the solid until a bubble large enough to lift the particle is formed, while the purpose of an oil is to form a persistent froth so that the particle will not be dropped back into the pulp. I am of the opinion that all the phenomena cited by Mr. Durell constitute no proof of any part of his hypothesis, but only furnish the basis for an inference that such could be the case. Whether it is possible to get flotation from water containing no dissolved gases and with minerals that have been treated for the removal of their occluded gases, no one knows. Possibly Mr. Durell is right when he says that "this phenomenon is worthy of investigation," but, on the other hand, I believe that flotation can be explained more satisfactorily than by the conjecture that well crystallized minerals, such as the metallic sulphides, contain important amounts of either occluded or dissolved gases, and that they contain these gases in any greater amount than do the equally well crystallized gangue-minerals, such as quartz and feldspar. That sur-

*Communicated by D. A. Lyon, metallurgist in charge of Utah Experiment Station, U. S. Bureau of Mines and Department of Metallurgical Research of University of Utah, Salt Lake City, Utah. O. C. Ralston, assistant metallurgist.

[1] *Philosophical Magazine*, Vol. XVIII, page 916, 1909.

[2] See the researches of Sir James Dewar on charcoal, published in various volumes of *Chemical News*.

face films of adsorbed gas or air exist and may be of great importance, I firmly believe, but there is little evidence of any great difference in the amounts of this gas on gangue and on flotative minerals.

As I understand Mr. Durell, the sole use of the oil in froth-flotation is the formation of a tougher liquid film around the bubbles of air, so that the resulting froth is more persistent. Mr. Rickard[3] has pointed out that various writers have continually made the statement that the surface tension of water is *increased* by the addition of the oil, while as a matter of fact it is *decreased*. This fact Mr. Durell acknowledges, and yet he states that because the surface tension of the water is decreased the tendency to float is likewise decreased. He implies that the reason is because the bubbles burst more easily. This seems strange, but in the absence of further data we can let it pass. My main comment is that while Mr. Durell believes that the only function of oil is the toughening of the surface film, we are not sure that such is the case. His hypothesis about "nascent" gas and "occluded" gas does not require the presence of oil; hence he has had to explain the use of oil or abandon the hypothesis.

Although I consider that Mr. Durell should be applauded for his courage in putting forward a hypothesis concerning a subject that has been of so empirical a nature up to date, nevertheless I have felt the necessity for challenging Mr. Durell's hypothesis and of taking the liberty of advancing what seems to me to be a better one.

There are two such hypotheses which seem to be equally possible and it is not certain but that the two simply cover parts of a greater fact. One hypothesis can be stated in terms of the inter-facial tensions involved, and the other in terms of the electric charges residing on suspended particles.

The first hypothesis is based on some academic work done by Reinders.[4] He based his work on some equations that Clerk Maxwell[5] had derived from fundamental thermo-dynamic laws, leading up to a certain set of inequalities between inter-facial tensions of the phases involved. By 'inter-facial tension' I mean the state of strain existing at the zone of meeting of any two dissimilar phases. The surface of water in contact with air is under a strain which we call 'surface tension,' so that this surface acts like a tightly-stretched rubber membrane. Likewise the inter-face between a solid and water and between a solid and air or between oil and water is under a similar strain. Allusion has been made already to the surface adsorption of air on solids. The inter-facial tensions of many pairs of liquids are known, as well as the surface tensions of all manner of liquids in contact with all manner of gases. However, the inter-facial tensions of solids in contact with liquids have never been studied thoroughly on account of the difficulty of getting measurements that mean anything. Reinders deduced the following inequalities as applying to the case where a powder, or the particles of a colloid, is suspended in a liquid to which is added a second liquid that is immiscible with the first. Let us assume that the first liquid is water and the second oil, then expressing the inter-facial tension between the solid and water as $T_{(s,w)}$, the tension between water and oil as $T_{(w,o)}$, and the tension between the solid and oil as $T_{(s,o)}$, Reinders stated that:

If $T_{(s,o)} > T_{(w,o)} + T_{(s,w)}$ the solid powder will remain suspended in the water.

If $T_{(w,s)} > T_{(w,o)} + T_{(o,s)}$ the solid will leave the water and go into the layer of oil.

If $T_{(w,o)} > T_{(s,w)} + T_{(s,o)}$, or if none of the three tensions is greater than the sum of the other two, the solid particles will collect at the boundary between the oil and water.

It hardly needs to be said that here we find something very close to the conditions obtaining in the flotation process. In fact, the old Elmore bulk-oil flotation method fulfills exactly the conditions that Reinders had in mind. Below are given some tables of results obtained by both Reinders and Hoffmann[6] in an experimental way, by suspending a definite powdered solid in water, adding a second immiscible liquid, and shaking. The letter *w* means that the powder remained in the water; the letter *o* means that the powder went into the oil layer; the letter *s* means that the powder went to the surface separating the oil from the water; and symbols like *s*(*w*) or *s*(*o*) mean that there was a good deal more of the powder in the inter-face than in the bracketed phase. Similar results were obtained with colloidal solutions.

Hoffmann worked a great deal with chemical precipitates and other artificially prepared products. However, the laboratory method involved ought to be good in the study of flotation processes for a possible method of floating oxidized minerals. Then it might be possible to convert a successful bulk-oil process into a frothing process in the same way as the old Elmore bulk-oil method went through the stage of granulation and classification to a final frothing process such as we see today. I have done some work along these lines and have planned considerable research work in the same direc-

tion. Meantime these notes might as well be available to others in suggesting lines of useful research. The comments to be made on the above tables are without end, but the tables are given here mainly to suggest the possibilities of further work.

The question arises as to whether it might not be possible to apply a set of inequalities such as those of Reinders, or even to apply Reinders' inequalities direct, in the prediction of results for froth flotation. In froth flotation we have at least four phases—solid, water, oil, and gas—unless the oil happens to be soluble in water,

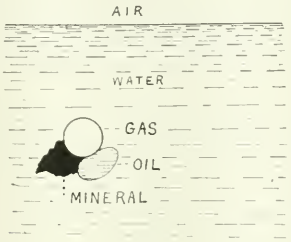

Fig. 1.

in which case we are reduced to a solid, a solution, and a gas. We have inter-facial tensions between each two of the phases, making six tensions altogether, and mathematical expressions covering such a case must necessarily be much more complex and exhibit a greater number of possibilities. The problem is more difficult, but it should be capable of solution. Fig. 1 shows a fanciful magnification of one possible arrangement of the particles of solid, droplets of oil, and spherules of air, in the liquid of the ore-pulp, being subjected to flotation, at the moment when a bubble begins to raise a particle of mineral to the surface.

Fig. 2 shows a possible way of applying Reinders' inequalities direct without any modification. It is assumed

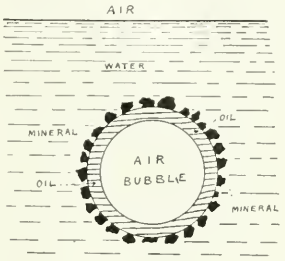

Fig. 2.

that the oil forms an envelope on the inner surface of the air bubble so that the air is nowhere in contact with water. Mr. Rickard[7] has called our attention to the

work of Devaux, published in the annual report of the Smithsonian Institute, in which it was found that a droplet of an oil when placed upon a plane surface of water will spread, of its own weight, until it forms a film only one or two molecules thick. This fact allows an explanation of how the small amount of oil used in the froth-flotation processes could be so efficient. If it so happens that the oil could coat the inner surface of an air bubble, the powdered mineral would be able to take up a position on the inter-face between the water and the oil without any reference to the air in the bubble.

By reason of the known low adhesiveness of oil and water it is doubtful if the air bubbles could be completely mantled by oil, as the oil would be too liable of its own weight to slide down to the bottom of the bubble to the position indicated in Fig. 3. Even here, the oil could carry mineral on its water inter-face (in case the oil and water do actually get into contact) and Reinders' criteria would still apply. In a Callow flotation machine having glass sides it is sometimes possible to see particles in just such a position. However, this case does not prove that the top side of the bubble is coated with oil or mineral, while the bubbles of a mineral froth on top of the pulp are seen to be covered completely with particles of mineral.

If the mineral tends to enter the oil phase completely and leave the water, the mineral grains present only an oil surface and in case oil droplets tend to collect at the inter-face between water and air (by Reinders' criteria) we could have the case illustrated in Fig. 4. This case, as well as the one illustrated in Fig. 2, would allow of the air bubbles becoming completely covered with oiled mineral.

Other phases are possible, but these are given to show how very feasible it is to get an explanation of flotation in terms of inter-facial tensions.

In an investigation conducted by the Minerals Separation, the 'contact angle' of various minerals with water was examined to find at what angle the mineral had to come in contact with a water surface before it was wetted and could sink.[8] A glance at Clerk Maxwell's famous paper on 'Capillarity,' upon which Reinders' work is based, will suggest immediately the explanation of a contact angle, and that it is the result of a certain equilibrium of inter-facial tensions of air, water, and solid. Valentiner[9] has likewise investigated the contact angle and its hysteresis under certain conditions and has connected it very definitely with capillary phenomena. There can be no doubt that there is a close parallelism between the angle of hysteresis of the contact angle and the ability of a mineral to float. But if we go no further than to observe the parallelism we cannot designate the statement of the parallelism as a theory, although we might be able to predict by its means whether a mineral would float.

To go into this a little farther, and indeed along the line suggested by Mr. Durell, we ought to consider the properties of the surface layers of the substances involved. For example, the plane surface of water in contact with air is known to have considerably different properties from the inner bulk of the water. In Fig. 5 the film is shown magnified in thickness. It acts like a tightly stretched elastic skin, due to what we have long called a 'surface tension' of 81 dynes per centimetre, as is usually given in text-books. (This means that for a strip of the surface film one centimetre wide, a longitudinal tension of 81 dynes has been measured at ordinary temperatures, and there is a definite tension for each temperature.) This tension of the surface film is one of its most commonly known properties, but some other interesting points about it are given in the following:

Its thickness, varying with temperature and other conditions, has been estimated[10] to be all the way from 4×10^{-5} to 10^{-8} cm. Its density averages 2.14 as compared with 1 for bulk water, although it is doubtless more dense at the immediate surface next to the air and gradually shades off into that of bulk water. This consideration probably explains the wide variation in the results of the measurement of the thickness, as one method might be less delicate than another and hence not take account of some of the layers of the film that are nearly bulk water in their properties. This average density, however, is illustrative of the magnitude of the force involved because water is a substance that resists compression, and it has been calculated from the known compressibility of water that the force necessary to compress it to twice its ordinary density is some thousands of atmospheres. Such a compression should liberate heat, and, in fact, the heat liberated when a definite area of new surface film is formed has been measured and found[11] to be 0.00315 cal. per sq. cm. Being so highly compressed, its specific heat might be expected to be different from that of bulk water and has been measured as being nearly 0.45 instead of 1. This low specific heat approximates that of ice.

One important property of this film is that it will often take up dissolved substances in different proportion from the amounts in which they are taken up in the bulk solution, and there is always a definite equilibrium between the two. This is known as surface concentration or 'surface adsorption,' and has been dealt with mostly in colloid chemistry, where the large amount of surface of the finely divided solids is large in comparison with their weight. In case a greater proportion of the substance is concentrated into the film than there is into the bulk water we have positive adsorption; and in the reverse case, negative adsorption. The properties of these inter-facial films have been found to be greatly modified by small amounts of dissolved substances and the properties of colloids are hence likewise greatly changed. The importance of the study of inter-facial films becomes obvious.

[11] *Ibid.*, 20:502, 1910.

Finally, there is a most important fact about the film of water in contact with air. It has been found that there is a difference of potential of 0.055 volts between the two surfaces of the film.[12] The density of the static electric charge at this potential is 4×10^{-5} coulombs per sq. cm. This electric charge is markedly influenced by electrolytes in solution and can be increased or decreased, even passing through zero and then increasing in the opposite sign. All inter-facial films have likewise been found to be charged in one way or other. Industrial applications of this fact are legion. All the technical handling of clays is now conditioned by the use of electrolytes in this manner, and the question of emulsions of all kinds of oils in water is closely bound up with it. Cottrell's precipitation process of suspended particles of solids or liquids in gases does not escape these considerations. Small particles of solids, liquids, or gases suspended in either liquid or gaseous media are found commonly to carry electric charges, due to various combina-

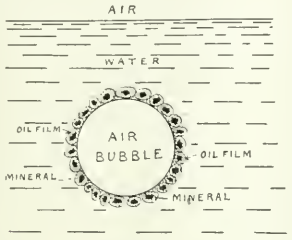

Fig. 4.

tions of factors which affect the double electric layer of the inter-facial films.

Since the size of many of the particles of minerals treated by flotation is of the same magnitude as that of many colloids we cannot escape from calling ore-slime "coarse suspension colloids," and must apply all the laws of colloid chemistry to our problem.

The electric charges on suspended particles allow another possible explanation of flotation phenomena. We find in some of the colloid chemical literature[13] that quartz particles when suspended in water are negatively charged, pyrite particles positively charged,[14] oil droplets are negatively charged, and air bubbles negatively charged.[15] The charges are somewhat small compared with the weight of the particles, so that they are hardly strong enough to cause negatively-charged quartz to stick to positively-charged pyrite, as they can have only a few points of contact, and currents in the water could easily tear them apart. However, the negatively-charged droplet of oil, which is repelled from a negatively-charged particle of quartz, can wrap itself around the positively-charged pyrite particle so that they will stick together, and the same applies to air bubbles. The other sulphides known to be flotative have positive charges when suspended in water or can be made to assume positive charges by the use of the proper amount of the proper electrolyte. So it can be seen that the application of these principles gives no difficulty in explaining flotation from an entirely new standpoint.* The large effect of a small amount of sulphuric acid on the conditions of flotation does not seem strange at all in this light, and we do not have to retreat to the purely imaginary supposition that osmotic pressure is acting through the surface of the mineral, as does Mr. Durell.

The inter-facial tension and the charge on the inter-facial film are two different physical properties of one and the same thing. I have shown that an appeal to either property is enough to build up a working picture of flotation phenomena that is simpler and more probable than that of Mr. Durell. I do not know how much there is in his contention that air bubbles will not attach themselves directly to the particles, or that only the dissolved air can thus attach itself; it may be that this is all correct, without interfering with the explanation that I have put forward. However, I hesitate to accept such a con-

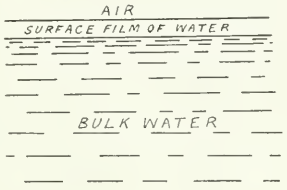

Fig. 5.

ception. The underlying cause of the tensions and of the electric charges is the same thing—some strange molecular, atomic, or other force manifested in 'adhesion,' 'cohesion,' or even 'gravitation,' if you please. No one can claim that electric charges carry the whole explanation of flotation, nor can it be stated that it is merely a question of a balancing of inter-facial tensions. Both will doubtless have to be considered.

Although much more could be said on the subject, I have only attempted to point out that there are certain scientific principles that can be applied to our problem, with great chances of success, in bringing us nearer to a definite understanding of flotation. Physical chemistry has been a recognized tool of metallurgists for some time, although little used by most of them, and now a particular branch of physical chemistry—colloid chemistry—is beckoning to us alluringly. All questions of the treatment of ore-slime should be studied in this new light. The results of an application of this idea in our own laboratory have been astonishing, and we hope that we may soon be able to publish them.

* It would appear that at the instigation of J. M. Callow, the Mellon Institute of Pittsburg, under the direction of R. C. Bacon, also formulated this same theory, and for a long time has done research work in this direction, this work and continuation of it at the Bureau of Mines at Salt Lake City seem to support the logic of this theory. A paper on the same subject was read by Mr. Callow at the October meeting of the American Institute of Mining Engineers in Salt Lake City.

Assayers and Their Ways

By G. L. SHELDON

While, as in all lines of business, the great majority of men engaged in assaying are honest, there are some black sheep even among them. Once, in Mexico, I spent nearly a month's time and $100 for assays while sampling a large mass of silicified porphyry. The samples were sent to a competent American assayer, who reported $1 to $5 in gold and silver. Later, when 10 general samples were sent to good assayers in the United States and checked, I obtained an average of 30c. It proved that the first man had left too much to his Mexican helper.

Again, in a lot of 30 to 40 samples, one from a 12-ft. vein returned 76 oz. silver. The remainder were all reported low. In writing to a friend in the United States I mentioned the matter. He immediately wired back a cash offer for an interest in the property. This was accepted, the claim located, and some work was done upon it. In the course of this work it was found that in the horn-spoon what appeared to be silver always appeared in fair amount. Several Mexicans, one an old man of large experience and a particularly good judge of ores, all agreed as to the silver. It, however, eventually proved to be a sulphide of zinc in a much decomposed and oxidized condition disseminated through the ore. Of many samples checked in the United States, none showed over 8 or 10 oz. silver and $5 to $6 gold. I even sent the assayer's affidavit of certificate of the 76 oz. to my friend, but I lost his confidence just the same. The prospect is open to location today.

I once received a $600 gold assay, from a 2-ft. porphyry vein, the sample being taken from the surface. I had the utmost confidence in the assayer, but I went and re-sampled the vein, cautioning him to use the utmost care in his work, and as a result received only a return of a few dollars. The sample must have been salted by the carelessness of the helper in not properly cleaning the bucking-board.

I have known assayers, not familiar with the kind of ore represented by a sample, to throw it out and give the prospector a certificate of a few dollars' gold. The discovery-hole dug during location work yielded ore that averaged 8 to 10 oz. gold per ton for the shipment. That was 20 years ago. The mine is still shipping and paying dividends, but the poor prospector lost his opportunity because of the dishonesty of the assayer.

The discoverer of the original vein in what is now a prominent producing district in the West gave an assayer a sample, promising him an interest in the claim if the sample was any good. When the assayer came to run it, he saw only white, apparently barren, quartz. It looked no good to him and he threw it out. The prospector, not being satisfied, took another sample and gave it to a different assayer. This one found the ore to be of high value. The first assayer, hearing of this, dug up his sample from the pile of discarded rubbish and ran it. Then he tried to locate the ground, but could not find the right place.

A prospector, returning to Seattle late in the fall from Alaska, gave an assayer there a sample that showed much gold. During the winter the assayer obtained the confidence of the prospector to such an extent that he learned where the sample came from, the two agreeing to locate the ground in the spring. But the assayer could not play fair. He took a friend with him and sailed on an early boat, determined to locate the ground and defraud the prospector. Fortunately for the latter, owing to the snow, the assayer was unable to find the place. Later the prospector located the ground, and the assayer, who was still in the neighborhood, lost his time and money.

Assaying is largely a matter of care, not allowing a sample to become salted, or changed. Honesty, of course, is absolutely necessary. From rather wide experience I have adopted the plan, so far as possible, of testing for gold and silver in the field in the horn-spoon. In the case of sulphide ore it is first necessary to roast. Of any sample showing enough to warrant assaying, one-half is sent to some assayer bearing a good reputation among mining men. If a good return is made, the remaining half of the original sample is again divided into two parts. One of these is sent to an assayer that I know by experience plays the game square. I retain one sample for any necessary check. In this manner I avoid the chance of losing any more good friends through poor assays.

Coal Mining Employs Many Men

The number of men employed in the coal mines of the United States in 1914 was 763,185, of whom 179,679 were engaged in mining anthracite and 583,506 in mining bituminous coal and lignite. The average number of days of employment of each man was 207, 195 for bituminous and lignite, and 245 for anthracite, according to the U. S. Geological Survey. In the bituminous mines the yearly average decreased from 837 tons in 1913 to 724 tons in 1914. The daily average increased from 3.61 to 3.71 tons. The average time made at the anthracite mines in 1914 was exceeded only by the records of 1911 (246 days) and 1913 (257 days). The average yearly production of anthracite by each employee decreased from 520 short tons in 1913 to 505 tons in 1914, owing to the fewer days worked. The daily output per man was 2.06 tons, a slight gain compared with 2.02 tons in 1913.

An oil-mill and machinery firm at Hull, in England, has a 'private picture palace' for showing its machinery in operation under various circumstances. An interesting variation is to send the films abroad, with or without a salesman, for the benefit of customers who might never have an opportunity to see the actual operation of the machinery in other countries.

Panama Canal now employs 21,677 men.

Hoisting-Works in the Park City District, Utah—II

By L. O. HOWARD

When in the course of mining the deeper orebodies, it became necessary for the Silver King Coalition Mines Co. to have one of its main working-points 1600 ft. below the surface of Silver Hill, it was decided to install a complete plant underground. The collar of the Silver Hill winze is so far below the surface that the necessary raising to reach the surface, and the unsuitable nature of the site for a surface-plant, were important factors in the decision. An outlet was already available through connections horizontally with the 500-ft. station of the King shaft, the main working-shaft of the company. Near this shaft are the main portions of the plant, as well as the mill, and the terminus of the aerial tramway connecting the mine with the railroad at Park City. There was another outlet through the Allianee adit, the portal of which is 8500 ft. from the Silver Hill winze in a different canyon from the King shaft. At this point are some minor units of plant, such as compressor, shops, store-houses, and timber-yard.

It was estimated that the Weber quartzite, just above the contact of which with the Park City formation the best ore has been found, was 1000 to 1200 ft. below the collar of the winze, and that a short drift to the north would cut the famous Crescent fissure at a greater depth than had yet been attained. A careful study of the mine had indicated that this portion of the property was destined to be very productive, so there was no hesitation in making the winze a centre of operations, and installing equipment of a magnitude equaled by but few of the mines in Utah.

The hoist was designed for lifting a working-load of 14,100 pounds in balance, from a depth of 1300 ft. This load is made up of 4800 lb. for two double-deck cages, 1800 lb. for rope, 1500 lb. for cars, and 6000 lb. for ore. The winze has two hoisting compartments, 4½ by 5 ft., and a pump- and man-way, 4 by 5 ft., and is timbered with 10 by 10s. The head-frame is of steel, and is set on high concrete piers. The principal dimensions are: height from foundation to centre of sheaves, 32½ ft.; width of tower, 28 ft.; spread of tower, 25 ft.; diameter of sheave, 6 ft.; diameter of auxiliary man-cage sheave, 31 in.; distance from centre of shaft to centre of hoist-reels, 43 ft. 9 inches.

The hoist is a Wellman-Seaver-Morgan, electrically driven, first motion, double-reel type. The motor is direct-connected by a solid coupling, and delivers 200 hp. at 65 r.p.m. Direct-current is supplied at 600 volts by a motor-generator set. Part of the specifications follow:

Outside diameter of reel, 10 ft. 6 in.

Inside diameter of reel, 3 ft. 6 in.

Capacity of reel, 1900 ft. of 4½ by ⅝ in. flat rope.

Diameter of shaft through bearings, 10 in.

Diameter of shaft through reels and clutches, 12 in.

Size of bearings, 10 by 12 in.

Clutches are Webster, Camp & Lane, friction type, 6 ft. diameter.

Brakes, parallel acting post type.

Diameter of brake-rings, 8 ft.

Brake and clutches actuated by weights released by air.

Indicator, ordinary gear-driven dial type.

The motor-generator set takes current at 2200 volts, 60 cycles, with a rated continuous input of 250 kva. The

PART OF HEAD-FRAME IN UNDERGROUND STATION.

generator is a commutating-pole, 600-volt, direct-current type, of 165 kw. capacity.

An automatic starting-panel is so arranged that the motor can be started by a push-button. Exciting current for the synchronous motor, generator, and hoist motor is furnished by a 15-kw. motor-generator set. The motor of this set takes current at 220 volts, 3-phase, 60-cycle, and the generator delivers direct current at 125 volts. Current for the exciter set and lighting the station is furnished by two 2200 to 110/220-volt transformers of 10 kva. capacity.

The hoist-motor has a pulley for driving a Sullivan WJ-3, 11 by 11 by 14, angle-compound compressor,

compressing to 27 lb. per sq. in. within the horizontal cylinder and to 100 lb. per sq. in. within the vertical high-pressure cylinder. Air-displacement at 215 r.p.m. is 887 cu. ft. per minute. The compressor and the hoist are so interlocked that when the hoist is started the compressor is unloaded and runs at no load during the hoisting period.

At the portal of the Alliance adit is a transformer-station taking power at 11,000 volts from the lines of the Utah Power & Light Co., and delivering current to the feed-cables at 2300 volts. The transformer-station is 20 by 25 ft. with concrete walls and corrugated-iron roof. In it are housed transformers of 600 kva. capacity. To take the current underground 10,000 ft. of cable is required. It is made up of three copper conductors, 2/0 Brown & Sharpe standard. Each conductor is insulated with 5/64 in. of varnished cambric. The conductors are insulated from the lead sheath by 1/16 in. of the same material. The lead sheath is 3/32 in. thick, and covered with 0.15 in. of jute, two layers of steel-band armor, and another 0.15-in. layer of jute. The diameter is 2.55 in., and the weight, 6⅔ lb. per foot. All joints are made by means of pot-heads.

This careful insulation was made necessary by the high voltage at which the current was carried underground, and the severe service conditions. The cable was laid along the bottom of the adit near one side and covered with light boards.

The hoisting equipment is placed in one room and the compressor, switchboards, and exciter set in an adjoining room, separated from the hoist-room by a 4-ft. reinforced-concrete wall. Both rooms have arched roofs. The span of the hoist-room roof is 35 ft. At the back it is 12½ ft. high, gradually rising toward the shaft 1½ ft. in 5. The compressor-room is 42 by 30 ft. and 20 ft. high, with an elliptical roof-arch having its major axis horizontal. Old 56-lb. rails, bent to the same arc as the arch, are imbedded in concrete at intervals of 2½ ft. Old 4-in. boiler-flues were placed above the rails. Where the back was strong enough, the rails were slung in loops of old cable hung in eye-bolts. Two 20-in. I-beams, laid side by side, and cut 50 ft. long to give good bearings in solid rock, support the crown of the arch. As a centre-support for the I-beams there was erected an extra-heavy 12-in. iron column filled with cement. All the walls of the rooms are 4 to 5 ft. thick, of heavily reinforced-concrete. In cutting the station great care was necessary. The lime proved heavier than anticipated. A fault passed between the two rooms, making very heavy ground.

In excavating for the rooms a slice was first taken for the width of the room and one set high, and timbered with square sets. Ten by ten timbers, cut and framed so as to be available in the shaft later, were used. Excavation proceeded by raising and taking a second slice, then a third. Posts resting on the square sets supported the back. Tailing from the mill was brought in mine-cars to the King shaft, lowered to the 500-ft. level and trammed to the station. Rock was prepared from the excavated material by crushing in a Dodge breaker and screening. In the hoist-room, which was completed last, the concrete mixer was placed at the top of the room and the concrete chuted to the forms. A 1:2½:5 mixture was used.

A short distance from the station the haulage-way is three tracks wide, providing room for storage of empties and loaded cars, and switching. The station may be approached from either side, by means of a loop. Blacksmith-shop and drill-sharpener have also been placed at the station.

Ore and waste are hoisted through the Silver Hill winze in skips and dumped into pockets in the head-frame. From this cars are loaded with waste to be hauled out through the Alliance adit to the waste-dump. Ore is hauled to the 500-ft. level of the King shaft, hoisted on cages to the surface, and trammed, if first-class, to the upper terminus of the aerial tramway through the sampler. Second-class ore is hauled directly to the mill.

The Silver Hill station is well lighted and ventilated. The photographs accompanying this article were taken with the ordinary lighting of the station. The work of cutting the station and installing the equipment was done under the direction of James Hume, superintendent, and James Toole, master-mechanic. The station was dedicated by a party of directors and stockholders in April 1914.

There are two main openings to the Daly-Judge mine, the Anchor tunnel, and the Anchor shaft. The portal of the adit is at the bottom of Empire canyon, about a quarter of a mile above the company's mill, and one mile from Park City, or midway between Park City and the Daly West mine. It is the main entry; men and supplies are hauled in through it, and the ore and waste taken out through it. It is driven 6625 ft. in a straight line to the 1200-ft. level of the Anchor shaft, the collar of which is well up the canyon. Electric haulage is used.

The Anchor shaft has a depth of 1600 ft. It has two 4½ by 5-ft. compartments, with a small pump and manway. Ten-by-ten timbers are used throughout. Hoisting and lowering to the 1200-ft. level is done by a flat-rope and reel-hoist, placed on the surface. The hoisting engine is a 20 by 60-in. Bullock first-motion duplex. The rope is ½ by 5 in. The reels have a maximum diameter of 12 ft. The head-frame is of wood, 60 ft. high.

A Nordberg 16½ by 28 in. by 36 in. two-stage compressor with a displacement of 2100 cu. ft., compressing to 100 lb. per sq. in., is rope-driven by a 350-hp. General Electric induction motor, taking current at 440 volts, through a transformer-station that receives current at 6600 volts.

The probably long life of the mine warrants new equipment, as the old has seen many years of service. Plans for a new head-frame and hoist are practically complete. The new head-frame will be of steel, 70 ft. high. The width of the tower will be 36 ft. and the spread 50 ft. The distance from the centre line of the drums to the centre of shaft will be 110 ft. The diameter of the sheave will be 7 feet.

PORTAL OF ANCHOR TUNNEL, PARK CITY.

The hoist is to be an Allis-Chalmers double-reel type, electrically driven. The principal data are:

Rope-pull, 20,100 lb., made up of 2600 lb. for double-deck cage, 2300 lb. for two cars, 9200 lb. for rope, and 6000 lb. for ore.

Minimum diameter of reel, 3 feet.

Maximum diameter of reel, 13 feet.

Clutch, segmental disc type, 8 ft. diameter.

Diameter of shaft through brakes and clutches, 13 inches.

Diameter of shaft through end bearings, 10 inches.

Size of bearings, main, 13 by 20 in., end, 10 by 24 inches.

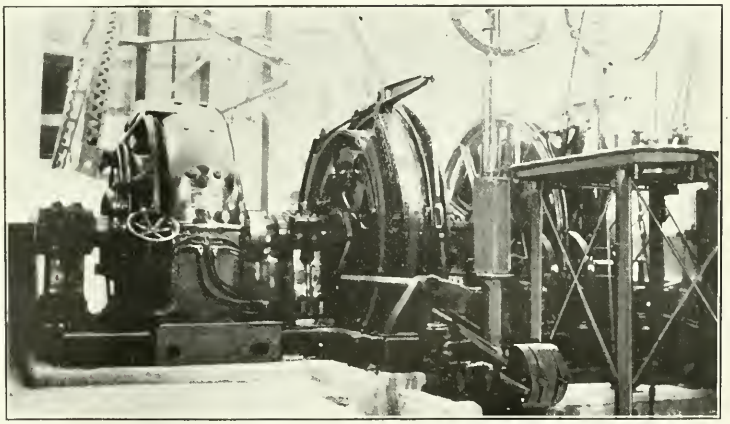
Brake, parallel acting post type.

Diameter of brake-ring, 9 feet.

Capacity of reels, 2500 ft. of $5\frac{1}{2}$ by $\frac{3}{8}$-in. rope.

Rope speed, 1500 ft. per minute.

The hoist is a second-motion type, driven through Wuest gears by an Allis-Chalmers 400-hp. slip-ring motor, taking current at 440 volts, 3-phase, 60 cycles. The motor-shaft will have a flexible coupling. Control is to be maintained by a moveable-electrode liquid-rheostat. The design involves heavy electrode plates moved in and out of the electrode by means of an oil-cylinder. All other

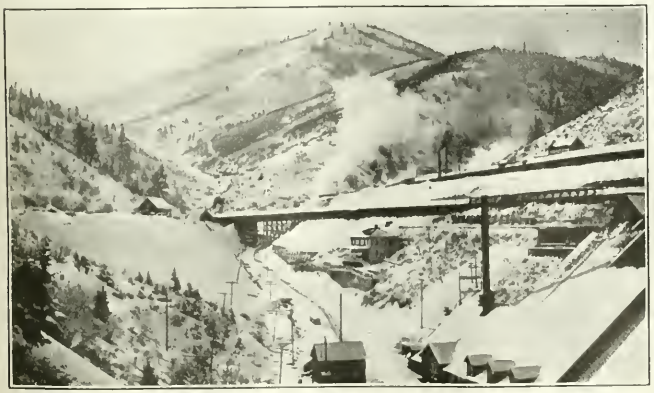


HOIST UNDERGROUND IN SILVER KING COALITION MINE.

auxiliaries are to be oil-operated. For control of the brakes there will be a duplicate oil-pump, and a dead-weight accumulator with a total reserve capable of operating one brake 20 times. The indicator will be of the compensated dial type, with $5\frac{1}{2}$-in. movement for every 100 ft. of depth. To promote safety there will be below the indicator red and green lighted arrows, which will indicate the direction of hoisting.

Considering the three hoists that I have described, it will be noted that they have many points of difference. For convenience of reference, I have grouped the principal data in the following table:

Many points of comparison are emphasized by this table; and to a few



EMPIRE CANYON, PARK CITY.

Showing Daly-Judge mill, and snow-sheds from Anchor Tunnel to waste-dump; also upper snow-shed from Alliance Tunnel of Silver King Coalition.

of these I would call attention. The most interesting is the difference in control. At the Silver King Coalition, the control is electrical, and this hoist has been operated out of balance, hoisting ore in one skip, without use of the brakes for days at a time, which speaks volumes for the efficacy of the control. The fixed electrode liquid rheostat is standard for large hoists, and it will be interesting to note the result of the application of the movable electrode rheostat. The Silver King hoist also illustrates a type of plant wherein an attempt is made to avoid high peaks. The advantages are obvious. For hoisting large loads from greater depths, second-motion hoists are favored. Reel and flat rope hoists continue the favorites in this district as well as in the rest of the State; the advantages of shorter shaft, better balancing of loads, etc., have justified its use here. However, we find one company abandoning the use of it in favor of the cheaper first cost, and generally longer wear of rope, of the drum type.

The three installations add further emphasis to the steady supersession of steam by electricity, since the problems of control have been solved.

The Standard of Value. The transactions of the civilized world are based on gold. It is, however, far from an ideal standard of value. In the first place, the supply is too variable. From 1800 to 1850 the annual output was around $10,000,000; by 1895 the production had increased 20-fold to $200,000,000 yearly, and in 1913 the maximum output of over $463,000,000 was attained. The consensus of opinion among well informed engineers is that the production of gold will decrease materially within the next twenty years, but it seems likely that the business of the world will continue to augment for centuries. Hence, the supply of gold, the standard of value, bears no relation to the amount of work it will have to do. This lack of relation between the volume of the world's trade and the production of gold must have a potent influence on prices, although economists differ as to the exact effect. The reason for this difference of opinion is that the influence of the varying gold production has been obscured by changes in the methods of financing trade operations, for example, by the greater use of checks, drafts, telegraphic transfers, and other forms of paper money. Another obscuring cause is the reduction in costs due to improved methods of manufacture, an excellent example of such reduction being afforded in electric lighting. On the other hand, the failure of producers to increase the supply of their commodities with the increased demand tends to raise prices; this effect is plainly seen in the cattle-raising industry of the United States, where the increase of population of 10,000,000 (1910-1914) has been accompanied by a decreas of 10,000,000 in the number of cattle; this shortage has naturally increased the price of meat. Therefore, although prices have advanced as a whole it is impossible to prove that the increased production of gold has raised the general price-level. Until within a few months, the universally accepted theory was that the more gold a nation has the better its financial position. Today we find a new doctrine in vogue and see the leading financiers of the United States trying to stop the influx of gold from Europe. They fear that a superabundance of gold in the vaults of our banks will lead to wild speculation. Possibly in the dim future men will be sensible enough to evolve some better standard of values than that of a metal produced so unevenly and so dangerous both to him who has too little and to him who has too much—nations as well as persons.

Mulga, a hardwood of the Western Australian goldfields, has a calorific value of 7000 B.T.U., against 14,000 B.T.U. in good bituminous coal.

The Geology of Iron Mountain

By OSCAR H. HERSHEY

Introduction. The present writer is the geological member of the engineering firm that holds the position of consulting engineers to the Mountain Copper Company, Ltd. This company operates a group of mines at and near Iron Mountain in the 'copper belt' of Shasta county, California. On my periodic visits to the mines, I have made a surface geological map of about 1.2 square miles on a scale of 100 ft. to the inch. It is based on a good topographical map that was made by E. L. Stenger, a former mine-surveyor. This map has 25-ft. contours, and indicates the position of houses, roads, tunnels, triangulation stations, and diamond-drill holes, to which the geologic boundaries have been tied. Beyond the contours I made a rough compass and pacing survey. In preparing the reduced-scale map to accompany this paper I have had to sacrifice most of the cultural features and have used the 100-ft. contours only.

The large scale of the map permitted working out the geology in a detailed manner that has, so far as I am aware, never before been attempted in any portion of the Shasta copper belt west of the Sacramento river. J. S. Diller, in preparing the Redding folio of the Geologic Atlas of the United States, working on a scale of 2 miles per inch, found it necessary to greatly generalize the mapping of the acid rocks of the copper belt. At a later date a special study of the belt was made for the U. S. Geological Survey by L. C. Graton, assisted by B. S. Butler[1]. They used a larger-scale map, but not one that would admit of the detail of my Iron Mountain map. Without intending criticism of the work of the Federal geologists, I may be permitted to suggest that their treatment, by force of unavoidable circumstances, of the alaskitic rocks of the copper belt as largely a single intrusive mass instead of a complex of relatively small intrusive bodies has led to some erroneous conclusions, or rather to an avoidance of some obvious conclusions, regarding the relation between the structure of the rocks and the form and distribution of the mineral deposits.

As Mr. Diller had made an elaborate microscopical study of the Shasta rocks, I submitted to him a small set of thin sections from diamond-drill cores at Iron Mountain. These were studied by his assistant, H. G. Ferguson, who kindly furnished me notes on the petrography, the substance of which I shall use in this paper. I may say that this paper is published at the request of Mr. Diller and with the permission of the board of directors of the Mountain Copper Company. A comprehensive discussion of the mineral deposits would be premature as I have not come to a definite conclusion in regard to the source of the mineralizing solutions, but I can go into the subject sufficiently to make this paper proper for a mining journal and of general interest to those living in the copper belt.

Copley Formation. The oldest formation exposed within the limits of my Iron Mountain map is the Copley meta-andesite. The age is not definitely known except that it is younger than certain Archean schists and older than the Kennett formation of Devonian age. The formation originally consisted of a thick series of lava-sheets and tuffs, chiefly of pyroxene-andesite. My early studies of the formation were confined to an extensive area west of the copper belt, from which I described it in 1901 under the term Clear Creek greenstone[2]. I referred to it as diabase, deriving the term from its early application by the U. S. Geological Survey to similar rocks in the Sierra Nevada region. Mr. Diller studied it near the Sacramento river, and for its petrography the reader is referred to his discussion in the Redding folio, published in 1906. In the Iron Mountain region I recognize three members. They remain in fragments only, but if the alaskitic intrusions had not occurred, the area would be crossed by three meta-andesite belts trending in a north-east direction. The south-east portion would be underlain by a broad belt of compact fine-grained meta-andesite lava. This would be followed, going north-west, by a relatively narrow belt of amygdaloidal lava. The remainder of the area would be included in a broad belt of coarse volcanic agglomerate. The latter is made up of rounded fragments of meta-andesite, in large part amygdaloidal, that have been cemented into a hard rock. The three members have been tilted to a nearly vertical position. This fact has had an important influence on subsequent structural features of the district, even to the distribution of the sulphide orebodies. The alaskitic intrusions tended to follow the strike and dip of the beds of the andesite series and thus acquired the north-east elongation which a glance at the map shows to be characteristic of the district. The Copley fragments retain, in a general way, their original attitude.

Bragdon Formation. On the north-west border of the map there is a small area of gray hard shale that weathers light-brown and pink. This is an outlier of a large area of the Bragdon formation that lies north-west of Iron Mountain and consists of conglomerates, sandstones, carbonaceous slates, and shales. In my early work on this formation I placed it in the Jurassic group, but in recent years the Geological Survey, on the basis of some obscure fossil localities, has classed it as early Carboniferous. In places it rests unconformably on the Kennett shales and limestones and its conglomerates con-

[1] 'The Occurrence of Copper in Shasta County, California,' by L. C. Graton, Bull. 430-B, U. S. Geol. Surv., 1910.

[2] 'Metamorphic Formations of Northwestern California,' *American Geologist*, April, 1901.

tain limestone pebbles with Devonian fossils. In other places, as in the extensive area discussed in my 1901 paper, it rests unconformably on the Copley series. That was probably the case in our Iron Mountain area, over all of which it extended in a thick series probably laid down after the meta-andesite had been tilted to a nearly vertical position and eroded to a plain. Here we have another fact that influenced subsequent structures. The main alaskite porphyry intrusion arose nearly vertically along the structure-planes of the meta-andesite and tended to spread out in laccolithic form under the Bragdon shale. The shale fragment remaining in the area is surrounded and intruded by dikes of this porphyry.

It dips south-east 25° and as the porphyry rises much higher in the direction of dip, without faulting, this is evidently a mass of shale that sank into the magma or projected down from the shale roof. That a portion of the porphyry intrusion of the copper belt in general approaches toward laccolithic conditions was noted by Mr. Graton.

Alaskite. In the Redding folio Mr. Diller mapped the acidic intrusives in the copper belt west of the Sacramento river mainly under one formation, the Balaklala rhyolite. At a later date Mr. Graton pronounced the Balaklala formation an alaskite-porphyry. Early in my work at Iron Mountain I became convinced that the products of several distinct stages of intrusion have been included under the name Balaklala. It is true that Mr. Diller excluded some dikes west of the Sacramento river as probably of later age, but even so recently as May of this year, the copper belt is mapped as comprised in one unbroken area of alaskite-porphyry.[3] However, Mr. Ferguson's work on the thin sections has demonstrated that there is at Iron Mountain a fine-grained, non-porphyritic alaskite that occurs in fairly large masses rather than in dike form. The rock is composed of a mass of interlocking grains of quartz and feldspar, small irregular patches of secondary chlorite, and, in places, a little sericite. The feldspar is usually albite. There are no phenocrysts in the thin sections. The grains vary from 0.06 to about 0.15 mm. in diameter. To the unaided eye, much of the rock has the appearance of a fine-grained white or pale greenish quartzite. When fresh it is very hard and it appears in the old diamond-drill records largely as 'felsite.'

In certain areas the alaskite formation is a breccia made up of acid fragments of varying texture, although most of them seem to be alaskite of the same variety as the large compact masses. Some areas consist exclusively of this breccia; some are made up of large masses of compact alaskite surrounded by the breccia; in others the breccia grades, along a fairly sharp line, into the main bodies of the alaskite; and, finally, there are places where the latter has a vaguely brecciated appearance on weathered surfaces, which disappears underground. The alaskite-breccia presents the same intrusive relation to the meta-andesite as does the compact alaskite; hence it cannot be looked upon as a surface phase. The explanation that suggests itself is that after the alaskite had solidified, certain portions were broken into fragments, partly fused and became embedded in an alaskite paste. The more prominent areas of breccia I have mapped separate from the remainder of the alaskite. Their rather rounded outlines suggest volcanic necks.

In the Iron Mountain area, the alaskite was intruded into the meta-andesite series in a broad belt with a northeast course. In this belt, the basic rocks in part remained in isolated, rather large inclusions, in a large measure retaining their original orientation. On both sides of the main belt, arms and small irregular areas of alaskite penetrate the meta-andesite. The intrusive relation between these formations is beyond question. The relation between the Bragdon shale and the alaskite is not known. Presumably the alaskite, like the alaskite-porphyry of the third series, is younger than the Bragdon formation, but of this there is no definite evidence. It is quite clear from the map that the alaskite represents an intrusion distinctly earlier than the alaskite-porphyry intrusions, but how much earlier we do not know. Mr. Ferguson takes the position[4] that the alaskite may be merely a fine-grained phase of the alaskite-porphyry intrusion, perhaps a slightly earlier and more quickly chilled portion of the intrusion. A somewhat similar idea must have been entertained by the other geologists who have studied the Shasta copper belt and made no attempt to separate the alaskitic phases. But upon my mapping a small portion of the belt on a much larger scale than anyone else has used, it becomes clear that the non-porphyritic alaskite represents a distinct and separate intrusion. This is proved by sharp contacts, by dikes of alaskite-porphyry cutting alaskite, by the presence of large angular inclusions of alaskite in the main porphyry mass and by the fact that a certain block of alaskite-porphyry, indicated on the map by dots added to the convention for the third series, abounds in angular and subangular small inclusions of alaskite. I regard the alaskite as representing an early stage of the same magma as the alaskite-porphyries.

Alaskite-Porphyry, First Series. Under this heading I include certain obscurely porphyritic dikes, with small, not very plentiful, quartz phenocrysts. These dikes are white, both when fresh and on weathered surfaces. In a few places the alaskite formation becomes faintly porphyritic and then some question arises as to whether it may not grade into this first series of porphyry dikes. Usually they are quite distinct. For instance, above the rock-quarry beside Slick Rock creek, a branched dike of obscurely porphyritic material has been intruded into the alaskite-breccia. Most of the dikes of this series occur chiefly in the meta-andesite lava in the south-eastern portion of the area mapped. The largest one, bordering on the quartz-diorite series, is about one-half mile long and over 300 ft. in maximum width. These dikes rarely meet the more coarsely porphyritic dikes, but as both types of rock occur in dikes of similar sizes in the same area, their

[3]'Pocket Deposits of the Klamath Mountains, California,' by H. G. Ferguson, *Economic Geology*, Vol. X, No. 3, April-May, 1915.

[4]Communicated.

differences cannot be attributed to the more rapid chilling of certain members of the same system.

Alaskite Porphyry. Second Series. These dikes vary from white to yellow where they outcrop and usually are strongly porphyritic, abounding in quartz phenocrysts varying from medium to large size. Petrographically they do not differ materially from the alaskite-porphyry dikes of the third series and I would be unable to separate them if it were not that they are cut by the so-called inter-porphyry breccia, whereas the third series dikes are younger than that breccia. Hence, I am able to map them in the vicinity of the breccia belts only.

Inter-Porphyry Breccia. Crossing the area mapped there is a peculiar zone of breccia consisting of angular and subangular fragments of meta-andesite, alaskite, and the obscurely porphyritic alaskite-porphyry; also of some coarse porphyry in the vicinity of certain dikes of the second series. It varies in width from a few feet to over 500 ft. and toward the north-east branches into two roughly parallel belts. As might be expected from its composition, it cuts through the obscurely porphyritic dikes it encounters and many of the coarsely porphyritic dikes. I have found two masses of coarsely porphyritic alaskite-porphyry that seem to have been intruded into it and one dike that seems to go through it. It is a little difficult to understand the conditions under which this breccia was formed. It occupies a fissure of greatly varying width along whose walls there has been no differential displacement; hence it is not a fault-breccia. Probably it is of the nature of certain breccia-filled fissures that may be found around the base of many volcanoes.

Alaskite-Porphyry. Third Series. The main mass of alaskite-porphyry, as determined by Mr. Ferguson, has prominent rounded quartz crystals, up to 2 mm. diameter. Feldspar was formerly present in a number of rather smaller crystals, but they have been completely altered to quartz-sericite aggregates. The ground-mass is largely quartz in very minute grains, with a small amount of sericite. This porphyry has been intruded largely in the form of a huge irregular dike on the site of the main alaskite mass. It also tended, as already stated, to spread out in a laccolithic form under the Bragdon formation. In the central portion of the map the alaskite-porphyry area is broad because the exposed surface is at relatively high altitudes. In the valley of Slick Rock creek it becomes much constricted and at the even lower levels on the north-east side of Boulder creek it is largely replaced by alaskite. However, high on the mountain beyond the north-east border of the area mapped it again spreads to considerable width.

In habit of occurrence, petrographic character, and appearance on outcrop, the main alaskite-porphyry mass cannot be distinguished from the smaller bodies that have been intruded into the inter-porphyry breccia. This is my chief reason for including the large mass in the third series; at the same time I must concede that there is little to discriminate it from the second series. In the meta-andesite and alaskite on the north of the large dike there are many smaller areas of similar porphyry, all of which I have mapped in the third series because I have no means of separating them if they also include second-series dikes.

I have carried my reconnaissance surveys over enough of the copper belt beyond the Iron Mountain area to know that the same complexity of alaskitic rocks obtains practically throughout the area of what has been mapped as the Balaklala alaskite-porphyry. Instead of being one great *massif* that should, from its size, have given rise to a granitic texture in the central portions, it is made up of the products of several periods of intrusion and no one intrusion is represented by a single very large body. Probably all the intruded material came from the same deep-lying magma. At first the magma was without quartz phenocrysts and the alaskite resulted. Gradually quartz crystals formed in the magma. When they were small and not abundant, there was an intrusion that formed the porphyry dikes of the first series. Later, after the quartz crystals had grown relatively large and numerous, an important intrusion began. While it was in progress, the inter-porphyry breccia was formed, enabling me, in its vicinity, to discriminate the earlier from the later dikes of the last great intrusion.

The name Balaklala was derived from the fact that the formation to which it was desired to apply the name forms the hills about the Balaklala mine. Most of these hills are chiefly normal or third-series alaskite-porphyry. Furthermore, it has been frequently stated that the sulphide orebodies occur in the Balaklala formation. For these reasons, the name clearly should be applied to the main alaskite-porphyry intrusion. The alaskite intrusion deserves a separate name, but no suitable geographic designation has yet appeared.

In the main alaskite-porphyry mass at Iron Mountain, there are a number of large inclusions of older rocks. Some of those that I now map as alaskite I once thought were silicified portions of presumably less basic members of the Copley volcanic series, as on outcrop they more nearly resemble the meta-andesite than the normal alaskite-porphyry. However, in the progress of my detailed field-work, I learned to discriminate them with comparative ease. The important fact is that these inclusions exist and their composition is of lesser significance from an economic standpoint. Those near the Iron Mountain mine are comparatively shallow, roughly lenticular masses, dipping at low angles.

Quartz-Diorite. The quartz-diorite that appears near the north-east corner of my map is a portion of a large mass that extends nearly to Keswick and south into the valley of Clear creek. It consists mainly of feldspars that are predominantly plagioclase, a little free quartz, and some ferro-magnesian mineral, either biotite or hornblende, or both. Where it enters the north-east portion of my mapped area it can be discriminated into two phases, which I have designated respectively as the fine-grained quartz-diorite and the coarse-grained quartz-diorite. There seems little doubt that the coarse-grained has been intruded into the fine-grained. My idea is that after the fine-grained quartz-diorite had crystallized, but not entirely cooled, there was another irruption of magma from below which resulted in the coarse-grained

phase. Dikes of the latter cut through to the border and one small area occurs entirely beyond the fine-grained quartz-diorite, hence it is not a case of a fine-grained border produced by chilling. Small irregular dikes of the coarse-grained are common in the fine-grained, and isolated inclusions of the latter are common in the former.

There are but few dikes of quartz-diorite beyond the main mass. A short distance east of the Bragdon area and a short distance south-east of the centre of the area mapped there are three small areas of crystalline rock that weathers light-brown and resembles the fine-grained quartz-diorite, under which designation I have mapped it, although not with entire confidence.

I am inclined to consider the quartz-diorite intrusions as younger than the alaskitic intrusions. That is the opinion held by most students of the region, but I infer from a statement made in Mr. Ferguson's latest paper, cited before[5], that he places the quartz-diorite intrusions first. The fact is that the evidence is not conclusive. I have searched along the border of the quartz-diorite area without a definite result. Recently some small dikes have been found in one of the mines that not only cut the main alaskite-porphyry, presumably of the third series, but also are post-mineral. They appear to be quartz-porphyries, but when studied microscopically may prove to be related to the quartz-diorite.

Lamprophyre. In the alaskite-porphyry in the south central portion of the area mapped, there are two chimney-like masses, almost too small to map, of a dark-gray fine-grained crystalline that I am terming 'lamprophyre' in the absence of a thorough investigation.

Brickyard Flat Sediments and Debris. Behind the crest of the high mountain that lies north and north-east of the old Iron Mountain mine, there is a relatively broad shallow depression floored by debris and an occasional stream cobble, overlying sandy clay that is probably a remnant of the creek deposit of an early system of drainage that has been completely destroyed in the surrounding country, leaving this short section of old valley high on the mountain.

Silicified and Pyritized Areas. The larger portion of the main mass of alaskite-porphyry at Iron Mountain and a few of the smaller masses have acquired a schistose structure as the result of compression. A small quantity of fine-grained pyrite is widely disseminated in these sheared areas. This was deposited by water. In certain large sections, the water has largely replaced the schistose rock by quartz and pyrite. Below the zone of oxidation the rock is a fine-grained white quartz (with remnants of the original minerals) through which pyrite is distributed. The pyrite may vary from a few widely-spaced grains to a rock that is chiefly pyrite with a cement of quartz. In the zone of oxidation, the pyrite has decayed, leaving a skeleton of quartz more or less stained by limonite. This is the material that I have mapped as silicified and pyritized areas. They are chiefly confined to a broad band crossing the district in a north-east direction. They are most strongly developed in the laccolithic portion of the alaskite-porphyry and hence at high levels. The large mass that extends down to Boulder creek is not an exception, for it is in a great landslide that has carried it down from a high level. A less favorable site is at the north border of the main alaskite-porphyry mass. Rarely has the material been formed from the alaskite.

Gossan. In certain portions of the altered alaskite-porphyry the replacement by pyrite and other sulphides has proceeded to the almost entire exclusion of secondary quartz and original rock-minerals, forming the 'sulphide orebodies.' Near the surface, oxidation and leaching have converted the material into a reddish-brown porous mass of limonite, mapped as gossan. A glance at the map will give one a fair idea of the original distribution of the sulphide bodies. They were practically confined to a broad belt trending in a north-east direction. The locus of this belt was fixed by the main alaskite-porphyry intrusion, the position and shape of which were governed by the alaskite intrusion. The latter received its north-east elongation from the initial tilting of the meta-andesite series. Thus we have a clear explanation of the major control of the distribution of the sulphide orebodies in the Iron Mountain region. I believe I can safely carry the matter to a further conclusion. In his preliminary report on the copper belt, Mr. Graton stated that the principal orebodies west of the Sacramento river are mostly rather flat-lying, but he offered no satisfactory explanation, though he suggested that in the arching up of the shales of the Kennett and Bragdon formations, the cooling porphyry may have been subjected to stresses resulting in flat zones of crushing and shearing. The sulphide orebodies are roughly lenticular masses. In the Iron Mountain region some of them dip at low angles and others stand on edge. It is an odd and doubtless significant fact that the low-dipping sulphide lenses are in that portion of the main alaskite-porphyry mass characterized by shallow low-dipping inclusions of alaskite and meta-andesite, and the sulphide lenses that stand on edge are near equally steep contacts between the alaskite-porphyry and the older rocks. In other words, the stresses that resulted in lenticular bodies of fractured porphyry were governed by the local contacts, a large rigid inclusion having the same effect as the walls of the main porphyry body.

Iron Ore. Under this heading I have mapped four areas of black heavy iron ore that occurs in connection with a large inclusion of meta-andesite agglomerate. The ore has a red streak, but is magnetic, from which I infer that it is a mixture of hematite and magnetite. Smaller masses of iron ore are scattered through the agglomerate. I am inclined to regard this ore as a contact-metamorphic deposit formed in the meta-andesite by the action of the surrounding alaskite-porphyry magma. The iron may have been derived from ferro-magnesian silicates in the meta-andesite. This raises a question of sufficiency of the source as the present mass is rather limited. Perhaps the metamorphism was the result of the early or alaskite stage, the mass being subsequently engulfed in the alaskite-porphyry.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Powdered coal burns best with 200 cu. ft. of air for each pound.

Overheating drill-steel in the blacksmith-shop destroys the carbon in the steel, rendering it useless. When this occurs the burned portion should be cut off.

Iron money, consisting of 100,000,000 5-pfennig pieces (100 pfennig = 1 mark = 25 cents U. S.) are now being circulated in Germany. They are to replace the copper and nickel coins heretofore in use.

The square-set method of mine timbering was first introduced in the Ophir mine on the Comstock Lode in 1860 by P. Deidesheimer. It has since been employed in every part of the world, many modifications of the original method being in use.

Altitude is not a factor of a gas or gasoline engine, which works equally well at high or low altitude. The engine depends upon the expansive force of the gas created by the ignition of the gas or vapor, which is entirely independent of the pressure of the atmosphere.

Extension of a crack in a sheet of metal may be stopped by drilling a hole where the crack ends. To determine this moisten the surface with petroleum, rub clean, and apply with chalk. The oil which has penetrated the finest crack, oozes out and becomes visible.

Work done within the boundaries of a patented group of mining claims in California can be applied as annual work to hold unpatented claims owned by the same people, provided the work is clearly shown to be directed toward and plainly designed to aid in developing the unpatented territory.

Use of oil for fuel for many industries on the Pacific Coast has affected coal mining in Washington and British Columbia. It is estimated that the consumption of California oil for fuel in the region is equivalent to about 21,000,000 tons of coal, or between 6 and 7 times the output of coal in Washington, or for that matter in all the Pacific Coast States combined, in 1914.

When a set of shaft-timbers is framed, it is well to fit it snugly together on the ground and bore a $\frac{3}{4}$-in. hole at each corner, penetrating both timbers. When the set is hung in the shaft, drive a wooden pin through the hole in each corner before screwing up the hangers. This will hold the set together with all joints tight, obviating the possibility of accidentally knocking an end-plate into the sump, or having to loosen the hangers because the corners opened. If the wooden-pin protrudes, the end can be broken off when ready to put in a set below. An old miner, recently questioned, did not know of this aid in hanging shaft-timbers.

The term 'coulee' is generally applied throughout the northern tier of States to any steep-sided gulch or water-channel, and at times even to a stream-valley of considerable length. The term was doubtless derived from the French verb *couler*, meaning to flow. This use of coulee should not be confused with the geologic use of the word, which signifies a solidified stream or sheet of lava.

Mosquitoes are generally thought to breed in water, but a recent report from Panama states that full-grown mosquito larvae were found in mud devoid of free water. They were the culex of an undetermined species. At the same time full-grown culex larvae were found alive and active in a surface pool of water over which there was an apparently unbroken film of crude oil, but the film was an old one.

Under a mining contract requiring a man to employ four men per day for 20 working days per month, and giving him the right to all the ore taken from a main adit without stoping, or to 40% of the ore taken from side drifts and stopes, he did not comply with its terms when he worked a less number of men for a greater number of hours, nor was he entitled to keep ore taken from an old adit or stope which had already been opened.

The ore deposits on Douglas island, Alaska, consist of mineralized dikes of albite-diorite intrusive in black slates, and belonging to a series of intrusive bodies that appear at intervals along a zone approximately 3000 ft. wide and three miles long. The mineralized dikes are cut by reticulating veinlets of quartz and calcite. Both dikes and veinlets may carry metallic sulphides and gold. Although a high gold-content may be found in picked specimens, the commercial value of the deposits lies in the wide dissemination of mineralization that renders great bodies of dike-material available as ore. The output to date is $58,318,780.

Explosives are briefly described in the following: Nitro-glycerine is made by treating glycerine with a mixture of nitric and sulphuric acids. It is a colorless, odorless, oily liquid. Nitro-cellulose is made by heating substances containing cellulose, like cotton, wood pulp, etc., with a mixture of nitric and sulphuric acids. Black powder is made by mixing 75% saltpetre, 10% sulphur, and 15% charcoal. Nitro-cellulose gunpowder is made by mixing nitro-cellulose with ether and alcohol. Dynamite is made by the absorption of nitro-glycerine in infusorial earth, wood pulp, etc. Picric acid is very powerful, and is made by mixing carbolic acid with nitric and sulphuric acids. Trinitroltoluene is made by mixing toluene, extracted from coal-tar, with nitric and sulphuric acids. Fulminate of mercury is made by treating quicksilver with nitric acid and alcohol.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BOSTON

Copper and Zinc Shares.—Ely, Nevada.—Boston Interests in California.—T. W. Lawson's Activities.

The copper share-market is getting symptomatic of forthcoming activity, possibly a big bull movement. The symptoms are the result of news from various copper districts. When market conditions are auspicious it is wonderful how much news comes in.

It has been a neck and neck race in the market between American Zinc and Butte & Superior, the 'zinc-dust twins,' but the former recently passed the latter in the quotations of stock. Some of the reasons given are that American Zinc has its own smelter, is not bothered with litigation, and produces high-grade spelter, in much demand by the cartridge-makers.

A Boston Stock Exchange house, in connection with New York interests, will shortly bring a new porphyry on the market. The name and situation are not given, except that the property is in Arizona. Its area is over 200 acres, and grade of ore is about 2.60% copper. Henry Krumb, is consulting engineer. The property is being drilled and a considerable quantity of ore occurs. [This is probably the Ray Hercules Copper Co., organized last week to absorb the Arizona Hercules Copper Co., working in the Ray district, Arizona, on what is said to be a continuation of the Ray Consolidated orebody. Directors are as follows: August Heckscher, director of the New Jersey Zinc Co.; Ellis P. Earle, vice-president of the Granby Consolidated company; J. Guthrie Hopkins, director of the Arizona Copper Co.; G. A. Huhn, banker, Philadelphia; W. F. Bartholomew, broker, Boston; Frank C. Armstrong, New York, president.—Editor.]

An examination for parties interested in the Coppermines company at Ely has been made by J. Parke Channing, and he is said to have recommended development, especially in that part of the property adjoining the Nevada Consolidated. It is understood that people close to Nevada Consolidated have acquired some of this stock, and it has been suggested that Nevada Consolidated control would like to take it over. The Coppermines area is over double that of its neighbor. The company is now receiving a good monthly revenue from the Nevada Consolidated through the latter's operations on the Ora claim of Coppermines.

Boston traders wonder why they are not given the opportunity to trade more in California mining and oil stocks. Such stocks, properly presented, would attract support. Early in June the Ventura Consolidated Oilfields was listed on the Curb, and removed a month later to the Exchange, on both markets making a strong and active record. Copper concerns, like First National, Trinity, and Calaveras, have done well here at times in a market way, but Boston has been led to hold an adverse opinion of California as a copper-producing state. The anti-smelter activities of the Shasta farmers has created a good deal of prejudice against the copper mines of California in the minds of Boston people. Not long ago the stock of the Globe Consolidated Mining Co., of Dedrick, Trinity county, was listed on the Curb, but the interests in charge of the market here were not such as to inspire confidence, as it appeared, and the stock 'died.' There is talk about shares in the Excelsior Consolidated Mines, Meadow Lake district, Nevada county, being brought out on the Curb. This property is controlled at Worcester, Massachusetts, and considerable money has been spent in preparing it for production. A revival of interest in the Meadow Lake district has been reported here. Should Trinity and First National combine, and the trouble with the farmers be adjusted in the Shasta area, a favorable opportunity will arise for renewed interest throughout New England in California mining enterprises. The Ames family, of transcontinental railroad fame, almost a generation ago spent a great deal of money equipping the Calaveras mines and estate.

The long absence of Thomas W. Lawson from the Street was broken a few days ago by his appearance in brokerage circles, looking himself again. It is said that he has formed a coalition with ex-Governor Foss to campaign the stock-market. He has addressed a circular to holders of First National Copper Co.'s stock, asking them for, in consideration of $1 and other valuable things, an option on their holdings of stock. Lawson has been actively conferring with New York, and it is believed a consolidation of Trinity and First National is to be proposed. Some time ago it was stated that the Bully Hill, Sugar Loaf, and one or two other properties were to go into this merger, with Lawson as President. Trinity has a property of 1700 acres, including a townsite; First National has about 1150 acres about three miles from Coram, and the Balaklala smelter at Coram; and Bully Hill has an estate of about 213 acres, situated about 25 miles north-east of the Balaklala smelter, equipment including a 250-ton smelter, which was closed down in the summer of 1910, the Forest Service claiming that the plant was damaging the trees. It is said that Lawson believes a big copper movement is coming, following the war babies. Another statement about Lawson credits him with joining forces with N. L. Amster, the well-known copper man, on Rock Island, the minority interests of which Mr. Amster has been championing for the past two years.

DEADWOOD, SOUTH DAKOTA

Rates for Ore Treatment.—Wasp No. 2 Dividends.—Blasting Accident.—North Homestake, Echo, Hidden Treasure.—Tungsten.

New rates for ore treatment have been made by the Mogul Mining Co., they are as follows: On ore worth up to $6 per ton, the charge is $1.50 per ton; on $6 to $8 material, $1.75, and on ore above $8, $2 per ton. The shipper is paid for 75% of the assay-value in gold. With the new oil engine in operation the capacity of the plant has been increased nearly 50%; it is now handling 150 tons daily. It probably will be possible to handle a greater quantity after some other improvements are made; one of the most important of these, so far as tonnage is concerned, will be completed when a second elevator is installed, work on which is now under way.

A dividend of 10c. per share, paid on October 11, marks the largest single distribution made by the Wasp No. 2 company. Former dividends this year have been at the rate of ½c. and 1c. each; the present is the fifth declaration of the year. The company has been shipping some wolframite ore, for which fancy prices have been received; but in the meanwhile the 500-ton mill has been making profits right along. The wolframite was extracted during the mining of gold ore.

Nearly a miracle occurred recently in the Oro Hondo shaft, when a miner was uninjured, although he was in the bottom

while a round of 15 holes exploded. It seems that he and two other men had given the hoisting engineer on the 1500-ft. level the blasting signal; had received the answer from the engineer, had spit the fuses, and given the hoisting signal. The engineer opened the throttle, pulled the bucket up about 4 ft., when the engine, which is driven by compressed air, stuck on a dead centre, probably because of the slow speed at which it was operating. In order to get it over the centre the engineer allowed the bucket to drop back, slowly, a short distance. Here one of the men got excited and jumped from the bucket, his light went out and he did not see the bucket disappear over his head. His companions missed him and grabbed the bell cord, gave the signal to stop, and about this time the man who had been left, started to climb the bell cord, thus giving the engineer another hoisting signal, which carried the bucket and two men to safety on the 1500-ft. level. Of course the bell cord parted before the man in the bottom had reached the timbers, and he found himself right in the middle of 15 holes loaded heavily and about to explode. Getting in a corner he barricaded himself with planks and heard eight of the holes go off; he says he heard no more until his companions returned to get his remains on top for the undertaker. He suffered a few bruises of a slight nature and a mental and nervous shock that incapacitated him for a few shifts, but was otherwise unharmed by his thrilling, and, to use an old expression which applies in this case, hairbreadth escape.

Work is progressing favorably at the North Homestake property, at Maitland, where a drift is being driven south, following a quartz vein in the schist. Assays are encouraging. This work, at a depth of 600 ft., nearly 400 ft. below the quartzite should disclose some interesting ore formations.

The Echo shaft, at Maitland, has reached a depth of 180 ft., and fair progress is being reported, notwithstanding extremely hard rock and all of the water that a No. 5 Cameron sinking pump will handle. A station is to be cut at 200 ft., and, lateral work done on that level.

Numerous 'ore-verticals' have been met with in the crosscuts at the 200-ft. level in the Hidden Treasure shaft, in Deadwood gulch. The east cross-cut has been advanced 60 ft., and 70 ft. of work has been done west.

Hill City is experiencing a small tungsten boom; but which gives promise of developing into something bigger, as energetic prospecting is exposing a considerable quantity of ore. Within a few weeks two mills will be busy concentrating the lower grades. Hand-sorted ores are shipped direct to the consumers. The American Tungsten Co.'s property shows one of the strongest veins. It is quartz, from two to eight feet wide, containing high-grade wolframite. On the Black Hills Tungsten Co.'s property are two well-defined veins of good ore. Both of these properties are equipped with mills. A small army of prospectors is working, and numerous locations are being recorded.

CRIPPLE CREEK, COLORADO

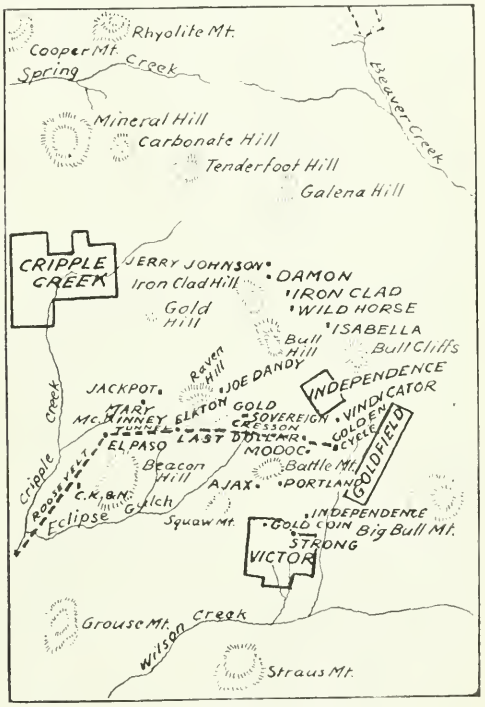
PORTLAND AND GOLD SOVEREIGN.—DRAINAGE TUNNEL.

The past week has been an important one for the district. Rich discoveries are being made nearly every day. While some of the reports are exaggerated by newspapers, yet when the truth is known they are often worth more than passing notice.

During the week important developments have been announced from the Portland, Gold Sovereign, C. O. D., and El Paso properties. Of these, the one officially reported by the Portland company is of greatest moment, both for its influence on future work on the deeper levels, and for its value to the district. On the 1800-ft. level the company has opened No. 1 vein, and as far as driven on it is as wide and assays as well as on No. 17 level, about 150 ft. above the new, or lowest, level. The persistency of good ore to such depths in the Portland will doubtless have a great influence on deep-level exploration on other properties being developed in the Cripple Creek district.

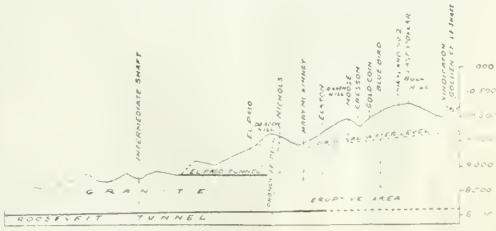
In the Gold Sovereign it is claimed that a continuation of the rich Cresson ore-shoot has been discovered. The Gold Sovereign adjoins the Maggie claim in which the Cresson company found the very rich ore last December. Ore in the new development is said to be similar to that in the Cresson, and contains high gold-content.

At a recent important meeting of the executive committee of the Cripple Creek Deep Drainage & Tunnel Co. at Colorado Springs, it was decided that the Tunnel should be driven in a straight line from the Elkton shaft to the main shaft of the



MAP OF CRIPPLE CREEK DISTRICT.

Golden Cycle. The distance between the two shafts is 8000 ft. T. R. Countryman was formally appointed chief engineer for the committee. The superintendent, Mr. Fuller, who



SECTION OF CRIPPLE CREEK, SHOWING DIRECTION OF DRAINAGE-TUNNEL.

is in charge of operations, reported a daily advance of more than 10 ft. per day. The Tunnel project was described by T. H. Sheldon in the *Engineering and Mining Journal* of October 2. Drainage of the district is all important for the future.

MONTERREY, MEXICO

Optimistic Feeling Resulting From Recognition of Carranza.

An immediate revival of business in the territory that is under the control of Carranza is probable, according to reports that have been received here from many centres. Large numbers of refugees are returning from the United States, and are resuming business. Orders for great quantities of machinery and general supplies have already been placed in the United States, and considerable trade in these lines will continue for some time replacing the depleted stocks of the merchants, and rehabilitate the industries of the country.

Much interest has been aroused by the announcement that 25 wholesale merchants and manufacturers of St. Louis, Missouri, have organized a trade excursion to visit Mexico in the early part of December. They will travel by special train, and will go as far south as Mexico City, stopping at Monterrey, Saltillo, San Luis Potosi, and other places.

Traveling representatives of San Antonio and El Paso concerns are already placing large orders in the territory where tranquility now reigns. In former times Mexico was a large buyer of goods and machinery in Germany, France and England. This source is now closed, and the United States will be called on for the supply. No anti-American sentiment exists among the native business and industrial element of Mexico. This feeling of antagonism towards the people of the United States is confined to a group of political agitators, and a small portion of the military class. The men who are really in charge of the reconstruction of the country realize fully that it is only by American trade and American capital that prosperity can be fully restored and maintained here.

During the long period of revolution, stocks in the stores became exhausted; machinery at the mines and mills grew rusty and obsolete; farm implements went to ruin; tracks and equipment of the railroads were destroyed or neglected; and it is now necessary that all these things be replaced in order that business may be able to resume its normal pace.

It is expected that mining and oil development especially will respond quickly to the influences of the promised era of peace. The copper resources of the country are known to be extensive, and in view of the high prices for base metals it is expected that much attention will be given to the development of such properties. The vast oilfields of the gulf coast region around Tampico are capable of larger output. There is a great deal of American and British capital already invested in oil lands, wells, pipe-lines, and refineries in that territory, and it is expected that with the establishment of a stable government in Mexico there will be great investment of capital from across the Rio Grande.

During the last few days many American farmers who abandoned their homes in different parts of Mexico during the period of turmoil have passed through here on their way back to their properties. Some of the settlers will have to begin all over again, but they seem to be optimistic as to the future.

KETCHIKAN, ALASKA

Ore Transport.—Smelter Charges.—Custom Plant.—Copper-Gold, and Gold Ore Producers.—Promising Prospects.

Transportation facilities are causing some delay in shipping ore from the small mines of this district. This is partly on account of the large amount of freight going out at this season of the year, such as fish from the canneries; and partly owing to the mines being located at some distance from the main steamer route. Large producers, which can guarantee a regular quantity at certain intervals, are usually not subject to these conditions, and can also procure lower freight and smelter rates on their ore.

Another difficulty of operating small mines here is caused by variable charges made by smelters. Recent instances are known whereby smelters have offered fairly reasonable rates to small properties, and then raising them much higher after the miners have gone to the expense of getting the ore ready for shipment. Smelter charges are somewhat confusing; one company deducts from 1 to 1.3% of the copper, as slag loss from the ore; another, while only deducting from 0.4 to 0.5% copper as slag loss, makes an excessive charge for smelting the ore.

It has often been suggested, and a petition has been sent to Washington, asking the Government to establish a reduction plant under the supervision of the Bureau of Mines, to consist of a concentrating mill and smelter, for treating custom ore in this district. A large number of small operators could send ore cheaply by utilizing small scows towed by gasoline boats, as nearly all the mines are on inside and protected waters. A competent staff, and appliances for conducting experimental research on the different ores would give the miners operating on small, as well as large properties, an opportunity to have their ore tested for suitable metallurgical processes at a reasonable cost. A situation for such a plant could easily be selected on one of the numerous harbors where sufficient water-power is available, and would be of great benefit in developing this district. There seems no reason why a plant of this kind should not be a commercial, as well as a developmental success.

The mines producing copper-gold ore at the rate of 500 to 1000 tons per month at present are the Jumbo at Sulzer, and Rush and Brown at Karta bay.——The It and Mamy mines are producing about 4000 tons per month.——The Cymru at North arm has a small amount of high-grade copper ore in bunkers waiting for transportation.——The Goodroe mine is being operated on a small scale and has some ore ready for shipment.

Among the gold mines, the Princton Mining Co. at Dolomi, is operating a 40-ton mill, and the management expects to continue operations throughout the winter; a shortage of water has hindered work at this mine during the unusual dry summer.——Dunton & Capp, under a lease from the owners, are shipping some high-grade gold ore from the Helm Bay property.——The Granite Mountain mine is being developed on a small scale by T. Stevens. An arrastra has been built for treating some of the high-grade free-milling ore opened. The vein carries mostly concentrating ore.——The Goldstream mine, at Ketchikan, has been sold to the It Mining Co., and is being pumped out.

A number of large copper-gold deposits are laying idle at present, the ore of which is too low grade for shipping to smelters, but is amenable to concentration by flotation, etc. No such treatment has yet been attempted here.

TORONTO, ONTARIO

Results at Kowkash.—Hollinger Production.

Interest in the Kowkash goldfield is well maintained by reports of further discoveries, that show the extent of the gold-producing area. Ore has been found near Redmond station, 12 miles west of Kowkash; about 8 miles north-east from the original discovery at Howard falls; and near the shore of O'Sullivan's lake, five miles farther north-east. All of these places are in the Keewatin belt, regarded by Percy Hopkins of the Geological Survey as being worth prospecting. Free gold is also stated to have been found along Gold creek, six miles south-west of the original discovery. The area immediately around the King Dodds claims is being actively developed, and a number of promising quartz veins and stringers have been disclosed.——On the Pullis claim, a long vein, 30-in. wide, of heavily mineralized quartz has been uncovered, and to the south across the river a dike of quartz and schist has yielded good assays. About 100 men were at last accounts engaged in development in the new district.

The Hollinger, at Porcupine, during the period ended September 9, made a gross profit of $149,935 from the treatment of 28,172 tons of ore. The average value was $9.03 and working costs $3.17 per ton milled. The total surplus is $1,331,461.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

In Bulletin 622 of the U. S. Geological Survey, by Alfred H. Brooks and others, the mineral resources of Alaska, and report on progress of investigations in 1914 are described. With maps and illustrations the publication covers 380 pages. Much of the information has been given in the PRESS as the preliminary reports were issued. On an appropriation of $100,000 for 1914, geologic surveys of all kinds covered 9025 square miles, and topographic 10,910 square miles.

The promise of adequate transportation facilities to the Willow Creek mining district by the building of a Government railroad to the interior, has increased the interest of Eastern capital, and resulted in greater activity by local operators. One of the latest developments is the incorporation of the Talkeetna Mining Co., headed by J. L. Fulton, of Portland, Indiana, which has taken over the claims of the Alaska Quartz Co. and the Matanuska Gold Mines Co. and will proceed to operate on an extensive scale. Associated with Mr. Fulton are Robert L. Hatcher and Eugene H. Bartholf, old-timers in the territory, and Judge P. C. Ellsworth of Seattle.

ARIZONA

Cochise County

The pay-roll of Douglas, including the two smelters, railroads, and other industries, is approximately $450,000 per month, and the place is prosperous and optimistic. Less concentrate is coming from Nacozari, owing to the revolution near-by.

At the Junction shaft of the Calumet & Arizona property, at Bisbee, motor haulage was started last week on the 1600-ft. level.

Concreting the Copper Queen Sacramento shaft was commenced early this week.

The Higgins Leasing Co. is doing a great deal of development, and continues shipments of ore. Twenty additional men have been put on.

Gila County

The Inspiration mill is treating 5000 tons per day. The mine is producing over 6000 tons, so the surplus goes to the Webster gulch storage-bins. Larger cylinders are being fitted to the Ingersoll-Rand compressor, also Rogler valves.

Greenlee County

Events in the Clifton-Morenci strike zone during the week were as follows:

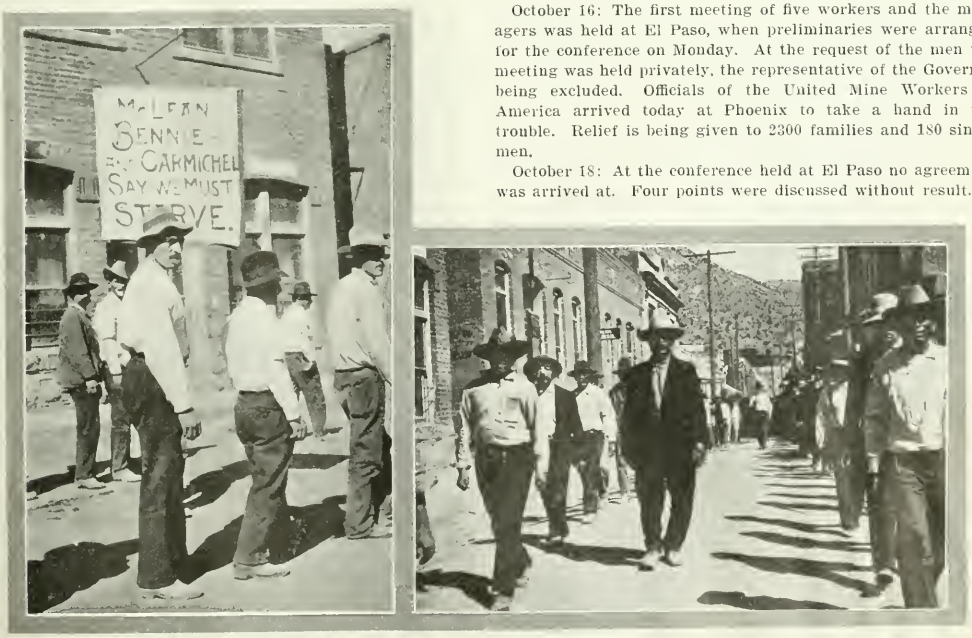
October 11: A committee of seven went from Clifton to El Paso to interview the managers of the copper companies shut down by the strike. The managers refused to meet more than five delegates, these to include no Western Federation men, but two representing the Mexican employees, and only the original grievances were to be discussed. The Governor of Arizona was very surprised at this action.

October 13: The strikers at Clifton choose 15 men, from whom the managers will select five for a discussion of the situation.

October 15: It is reported that there are signs of dissension among the strike leaders. The management of the relief fund is the subject of discussion.

October 16: The first meeting of five workers and the managers was held at El Paso, when preliminaries were arranged for the conference on Monday. At the request of the men the meeting was held privately, the representative of the Governor being excluded. Officials of the United Mine Workers of America arrived today at Phoenix to take a hand in the trouble. Relief is being given to 2300 families and 180 single men.

October 18: At the conference held at El Paso no agreement was arrived at. Four points were discussed without result.



STRIKERS' PARADE AT CLIFTON. NOTE THE MISLEADING STATEMENT ON THE BANNER, ALSO THE MEXICANS.

Mohave County

A special edition of the *Mohave County Miner* covers the mining industry of this county. The area is 13,500 sq. miles, of which 7000 are mineralized; the altitude is from 2000 to 7000 ft.; the population is 5000. The descriptive matter dealing with the mines of the region is suitably accompanied by good plans and photographs.

The monthly output of the county is approximately as follows: Golconda, $250,000; Tennessee, $150,000; Tom Reed, $100,000; Copper Giant, $100,000; Gold Road, $70,000; Champion, $35,000; and sundry $35,000; a total of $740,000. Tungsten ore is worth $35 per unit in this county, this being the price paid by the Primos Chemical Co., which buys the local ores. Molybdenite is $3500 per ton for 90% ore, and the mines at Copper Canyon will soon be benefiting from this high price. The American Molybdenum Co. is erecting a mill there.

Booming of the county continues.

CALIFORNIA

Amador County

The following is the preliminary report of the output and costs of the Plymouth Consolidated in September:

Ore milled, tons	10,800
Total value	$53,076
Working expenditure	$30,302
Development charges	$ 411
Surplus	$22,363
Other capital expended	$ 250

It is reported that the Kennedy company, which bought the Zeila mine at Jackson, is sinking a new shaft and experimenting with flotation to treat the low-grade ores.

The Original Amador is sinking its shaft, and will curtail work in the meantime.

The north shaft of the East Eureka mine near Sutter Creek is being prepared for resumption of operations. It has not been used for 20 years.

Butte County

According to Oroville papers the Forbestown district is having a big revival. Men are flocking into the place. A number of properties have changed hands, and other deals are under way. At the Forbestown Consolidated there are 25 men at work. The 20-stamp mill is being overhauled.

On October 19 the Viloro Syndicate's (London) dredge at Oroville was destroyed by fire, the result of a short-circuit. The boat had been digging over various areas and had enough ground for two years' work. The gold recovered had returned the original capital of £70,000. The last dividend year totaled 18¾%. The boat, insured for $50,000, was originally the California No. 3 of the Oroville Dredging Company.

Calaveras County

High-grade tungsten ore has been opened in the Rustle mine near San Andreas. The vein is 12 in. wide, and has been opened for 20 ft., giving indications of an extensive deposit.

Eldorado County

Six miles from Placerville the Webber Creek Mining Co. is preparing to mine its gravel with a steam-shovel, locomotive, side-dump cars, and sluice-boxes at the rate of 100 yd. per hour.

Kern County

(Special Correspondence.)—Legal action has been taken by Mrs. DePauw, widow of the late John Singleton, one of the owners of the Yellow Aster property, against attorney Ward Chapman, who is acting as executor of the Singleton estate. She contends that the attorney is evading the order of Judge Works of Los Angeles, commanding him as executor of the estate to pay $100 a month for the support of Singleton's 10-year old daughter. Coming on the heels of a recent action by Mrs. DePauw to gain control of the directorship of the Yellow Aster Mining Co. before Judge M. J. Rogers of Ventura, the case is creating unusual interest. In settlement of the estate recently a court decision was obtained granting Singleton's daughter one-fourth of the estate, and an allowance of $100 per month. John Singleton was one of the three partners who located the Yellow Aster group of claims here in 1895, comprising Burcham, Moers, and Singleton. Mrs. Rose Burcham, present secretary of the Yellow Aster company, widow of one of the original locators, has always been identified with the promotion and development of that property which has been for years the largest producing mine in Southern California. At present about 200 miners are employed in the mine and mill of 150 stamps. About 300 tons of ore is extracted and milled daily. During the eight months ended August 31, the gross earnings were $305,584, of which $106,516 was profit. Dividends absorbed $11,000, and most of the balance was spent on development and improvements.

Patrick H. Murphy, of Randsburg, aged 48 years, a well known miner, was killed by an explosion of a missed blast, near Silver lake, Mono county.

The old Goler placers are about to be re-worked through the efforts of former Senator Nathan Hale, of Tennessee, who has succeeded, after two years of disappointing labors, in developing water enough for placer mining purposes in the wash adjoining Goler, and just west of the Yellow Aster pumping-plant. Three wells are nearly completed, and water will be lifted by electric power from the Southern Sierra Power Co.'s line to a reservoir elevated about 300 ft. above Benson and Nugget gulches. It is proposed to re-use the water in working the old placer properties bonded and optioned by the Velmedith Mines Company.

J. F. Fienan, C. C. Passer, and other Randsburg miners, have just succeeded in recovering the old antimony mine near Havilah, by ejectment proceedings before Judge Farmer of Kern county. The increase in prices for antimony is responsible for re-opening of this property.

John M. Hepp, publisher of the *Randsburg Miner*, has a promising lease at the Sunshine mine.

Randsburg, October 10.

Nevada County

The Polar Star Mines Co., Oscar Coffin superintendent, is to develop its property thoroughly, and the Taylor Foundry & Engineering Co. of Grass Valley is to erect new machinery. This will consist of a large motor-driven hoist, motor-driven triplex pump, duplex Laidlaw-Dunn-Gordon air-compressor, and various General Electric motors.

After being unwatered, and some work done on the 400-ft. level of the Kenosha mine, the owner, G. F. Drake, has opened specimen ore, over 150 lb. of which is on view at Grass Valley.

The new 20-stamp mill at the Brunswick Consolidated started work on October 16. It consists of a 10 by 16-in. jaw-crusher, suspended feeders, twenty 1250-lb. stamps, copper plates, four Wilfley tables, and six Frue vanners. Motors drive everything.

Plumas County

In the Soda Creek district the Plumas Amalgamated Mines Co. owns 17 gold quartz claims. The Monitor group has been worked on and off for about 40 years. Keddie, on the Western Pacific railroad, is 15 miles east of the property. Haulage to the mine costs $10 per ton. Besides the usual equipment at the mine there is a 10-stamp Straub mill. A good tonnage of fair-grade ore has been opened in the claims, and possibilities are considered to be encouraging.

San Bernardino County

(Special Correspondence.)—A piece of scheelite float, over 200 lb. in weight, was found this week by Anderson and Roberts on their lease near here. High-grade scheelite, over 60% WO_3, is selling at $30 to $32 per unit, and is creating unusual activity among the 'float diggers.' Since finding the big lump, valued at over $200, the vein has been found, it being from 2 to 4 ft. wide, averaging about 20% WO_3.

Lessees at the Osdick properties near here have purchased

a 12-hp. engine and crusher, preparatory to installing jiggers and concentrators. An 8-ft. vein of scheelite of good quality has been opened about 30 ft. from the top of bed-rock nearly half a mile from the Atolia mill. Miners are jubilant, as this discovery insures a good future for the camp, which is now already a big tent city.

The Atolia Mining Co. is laying a pipe-line over the mountain to Randsburg, ostensibly to pump the surplus water from the Consolidated mines to this place. Heretofore all water used at Atolia has been hauled there by tank-cars over the Santa Fe. The new supply is said to be adequate for all purposes here, where there is a population of over 200 people.

Irving Hopper, who has tungsten interests near the Atolia company's ground, has gone for a Keystone drill with which to prospect the Osdick and Scheelite groups, comprising 16 claims.

Atolia, October 10.

Tuolumne County

The well-known Rawhide mine near Sonora has been sold to the Silver Peak Mining Co. of Nevada. John Mocene is superintendent. The shaft, 1800 ft. deep, is to be unwatered and re-timbered.

COLORADO

Boulder County

Tungsten ore producers of this country are receiving between $200,000 and $300,000 per month for their outputs. Sixty per cent ore is worth $1800 per ton. Miners in the Nederland area are making large profits. The Primos Chemical Co. is buying most of the ore, but the Crucible Steel Co. has entered the field.

Dolores County

The Rico district produced 62 cars of ore during September. Of this, 55 cars were from the Rico Wellington property, where 43 men are employed. Development in this, and the Rico Consolidated and Rico Carbonate is satisfactory.

Lake County (Leadville)

Approximately 120,000,000 gal. of water was pumped from the Down Town mines in August, according to Jesse F. McDonald. Since May 8 the Penrose pumps have discharged about five times this quantity. The pumps are now at 650 ft., where the shaft is not in very good condition.

Good progress is reported from the Anderson adit, and the surface of the property is busy during construction of plant.

The new dredge on the Derry land has been at work for two weeks, and attracts considerable attention.

Ouray County

Judging by the snow fallen in the mountains, winter has set in. About 5000 tons of 5% copper ore has been opened in some old workings of the Wanakah mine. The smelter is at work again.——Development at the Gold Crown Mining & Reduction Co.'s property is giving good results. The 300-ton mill will be finished early in January.

IDAHO

Custer County

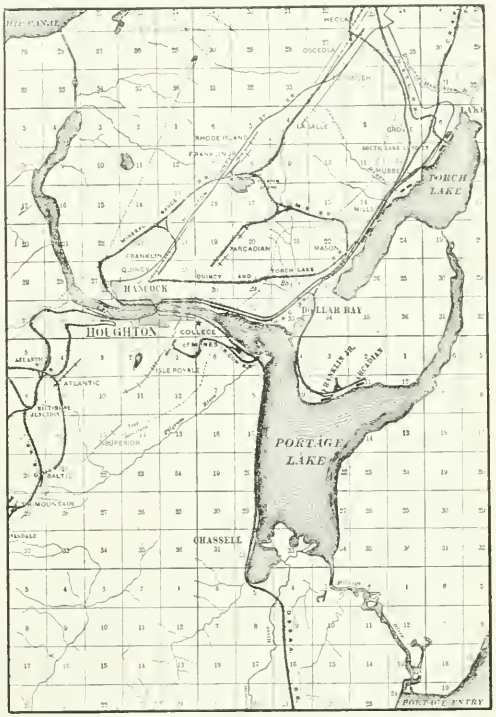
The Lost Packer Mining Co. held its annual meeting at Salt Lake City last week; James Ivers is president, and Henry Welsh secretary. The property is in good condition, and the new 50-ton mill will soon be finished, but will not start until next March. It will treat the lower-grade silicious ore, about $20 per ton, of which there is over 20,000 tons in the mine, according to the superintendent, John P. Boyle. The local smelter will reduce the concentrate and high-grade ore to matte. The smelter is of 100-ton capacity. Owing to its situation the mine is worked under serious difficulties.

MICHIGAN

The Copper Country

A heavy earth tremor or air-blast was felt over a considerable area of this region last week, no damage was reported from any of the mines.

Shipping through the Portage Lake waterway during September was as follows, east bound, 6019 tons copper, 5040 tons iron ore, 3200 tons mill sand, and total of all materials,



THE PORTAGE LAKE WATERWAY, MICHIGAN.

97,289 tons; west bound, 140,297 tons soft coal, 25,308 tons hard coal, 705 tons copper, 1936 tons nitrate of soda, 3348 tons limestone, 39,000 bbl. cement, 45,017 bbl. salt, and a total of all materials 215,906 tons. The quantities were less than in August.

MISSOURI

Jasper County

A large number of small companies are prospecting on the Missouri Lead & Zinc Co.'s area in the south-east part of Joplin. As one section has been drained, many sub-leases have been let. The company is drilling, and will lease the ground where ore is found.

Treatment of old dumps at the south end of Joplin is giving fair profits.

MONTANA

Beaverhead County

A 150-ton cyanide-plant is to be erected at the Bannack Gold Mining Co.'s mine at Bannack next spring. Over 150,000 tons of ore has been opened in the mine. Development is done by adits. George T. Hansen, Salt Lake City, is managing director.

Fergus County

(Special Correspondence.)—In spite of the litigation between the Kendall and Barnes-King companies that has prevented mining in the disputed ground in the North Moccasin mountains, development has been active in Fergus county this

summer. The outlook is excellent for the addition of a number of mines to the present producers in the Judith and North Moccasin mountains.

The Kendall company now employs 20 men on development, mostly below the 500-ft. level, and the mine will probably soon be an important gold producer again. The upper 300 ft. of the mine has been leased with half of the mill. The lessees are making a success of their venture, taking their ore chiefly from the open-cut.

The capitalization of the West Kendall company was increased from $1,000,000 to $2,000,000 at a meeting held at Lewistown, on October 2. Development has disclosed a large amount of gold ore, mostly low grade. In the spring the company proposes to erect a mill. A large building has just been finished to provide better winter accommodations.

Another property in the North Moccasin mountains on which development has been done is the Blue Belle, located by Foster and Helsing. A trial shipment of 17 tons of lead, silver, and copper ore yielded $30 per ton after paying a heavy penalty for its zinc content.

Six hundred feet of the adit on the Gold Acres property at New Year is now completed, and the president, A. S. Wright, expects that the orebody will be cut a few hundred feet farther in.

Hawkins and Sutter have been busy opening a copper claim in the Cone Butte district near Maiden in the Judith mountains. Some good ore has been found.

Peter Rosso, owner of the Silver Bullion mine near Maiden, is to erect a 15-stamp mill to treat the gold and silver ore he discovered recently. Some rich ore has been opened, the shaft being down 80 ft. If the gold-content persists in depth this will be important, as the vein is five feet wide; it has been traced for a length of 2000 feet.

Lewistown, October 5.

During September the Barnes-King Development Co.'s North Moccasin mine yielded $16,000 from 2900 tons of ore, and the Piegan-Gloster between $10,000 and $12,000. The dispute with the Kendall company is still pending.

Silverbow County

Representatives of the I. W. W., W. F. of M., and other labor combinations are reported to have tried to start trouble at Butte last week, but failed entirely. The situation is as desirable as could be at present.

The Davis-Daly mine is developing well, especially at 2500 ft. depth, where the Hesperus vein has been opened for 150 ft. It is 12 ft. wide, 5 ft. being first-class. The daily output is 100 tons of 6% ore.

The Elm Orlu-Butte and Superior suit commenced on October 18; great interest is being taken in the dispute. A large electric hoist, similar to that at the Granite Mountain shaft of the North Butte, constructed by the Nordberg and General Electric companies, has been ordered for the Elm Orlu. This and other improvements are to cost $125,000. The main shaft is to be sunk to 2500 ft. from 1700 ft. The Timber Butte mill, which treats the Elm Orlu ore, is treating by flotation 500 tons of 17 to 20% ore, extracting 94 per cent.

After a 40 days' shut-down, during which the plant has been overhauled and enlarged, the Butte-Alex Scott company resumed last week. The hoist has now a capacity of 3-ton skips from 3000-ft. depth. Ore is being extracted from 1900 and 2000 ft. In a few days the output will be 200 tons per day, and within 90 days 300 tons. The ore assays 5% copper.

A new hoist, Ingersoll-Rand air-compressor, and building, etc., have been erected at the Butte & Great Falls mine, six miles north-east of Butte. Everything is electrically driven. The mine is now to be unwatered, and development commenced. The officials are pleased with prospects.

The Jessie vein at 2800 ft. in the North Butte is 7 ft. wide, assaying 7% copper, with masses of 20% glance. The Granite Mountain shaft is to be sunk from 3000 to 3400 feet.

In the Anaconda-Pilot Butte suit the State supreme court has modified the order of the district court; the defendant can now increase its production. The 800-ton flotation-plant at the East Butte will soon be finished. Second-class ore and tailing will be treated.

The September output of the Butte and Superior was as follows: ore treated, 40,360 tons; concentrate saved, 11,579 tons; assay of concentrate, 55.92% zinc; recovery, 92.79%; and spelter in concentrate, 12,950,000 pounds.

During the lowering of powder down the North Butte's Granite Mountain shaft 15 men were killed by an explosion at the surface on October 19. The company is negotiating for the purchase of the Butte-Duluth property.

NEVADA

Humboldt County

A 50-ton tungsten concentrating-plant is being erected by the St. Anthony Mines Co. near Toy on the Southern Pacific line, 21 miles south-west of Lovelock. A good deal of ore is said to be ready in the mine for treatment.

The Friedman adit was in 1150 ft. on October 17, in hard rock. The Rochester Mines Co. has 2400 tons of mill ore broken in stopes.

Mineral County

The Louisiana Consolidated Mining Co. has acquired for $30,000 the Tip Top mine, 40 miles south of Mina. The property was sold in April to the Washoe County bank, to satisfy a judgment obtained by Walter E. Trent for plant supplied. He will remain as manager. The 10-stamp mill and cyanide-plant produced $80,000 in eight months. The plant will be enlarged.

Nye County

Tonopah mines last week produced 9761 tons of ore worth $201,658. Some September returns were as follows: Belmont, 12,008 tons for 226,844 oz. bullion, and a profit of $65,018; Jim Butler, profit of $22,232; and Tonopah Mining, 12,057 tons for 206,400 oz., and $51,720 profit.

Storey County

Five feet of ore on the hanging wall assaying $200, and 5 ft. on the foot-wall worth $20 per ton, was opened at 2500 ft. last week in the Union Consolidated, on the Comstock. The ore is being sent to the Mexican mill.

White Pine County

(Special Correspondence.)—A two-foot vein of scheelite, that can be traced through five claims, on the east side of the range, opposite the U. S. Tungsten Co.'s mine and mill, south of Osceola, has been opened by Marriott Bros. It is said to be high grade.

Lowe and associates recently shipped a carload of 70% lead ore from their property up Berry creek, east of McGill. They have a good property.

The shaft being sunk on the Willow Creek Con., south-west of Ely, averages $200 per ton across two feet at a depth of about 50 feet.

Ely, October 10.

According to the Nevada Consolidated company's *Safety First* for September there were seven disabling accidents at Copper Flat, four at the Ruth mine, six at the mill, and five at the smelter, none of which were very serious.

TEXAS

El Paso County

(Special Correspondence.)—Improvements to the A. S. & R. smelter at El Paso are to cost $300,000. Three large converters, electric cranes to carry molten matte to the converters, and a 300-ft. stack are part of the new equipment. The large increase in ores received from Arizona, New Mexico, and Texas, is responsible for the extension of plant; while more ore is expected from Mexico as affairs quiet there.

Regular shipments of copper-silver ore are being sent by

M. F. Jarrell from the Texas and Pacific mine near Allamore to the El Paso smelter.——S. Hackett in the same district expects to maintain one car of ore, high in silver, each week. ——Some promising copper claims have been located in the Carrizozo hills, between Allamore and Hot Wells, by L. R. Goldbaum of El Paso.

Up to the time of closing the railroad from Sierra Mojada to Escalon early in September, Paul Ginther of El Paso shipped over 500 tons of zinc carbonate ore from the Esmeralda and Constancia mines in Coahuila, Mexico, to the El Paso smelter.

El Paso, October 10.

UTAH

Juab County

The Iron Blossom company pays 5c. per share on October 25, equal to $50,000. The copper shoot at 900 ft. continues to open satisfactorily.——Work in the Ontario is being done as deep as 1500 ft. The low price of silver is a handicap to profitable operation.

The Eagle & Blue Bell mine will ship about 2500 tons of ore in October. Developments down to 1700 ft. are good. A large electric hoist is being installed. Profits to August 31 totaled $96,825, but are now at the rate of $200,000 per year.

A tailing-dump containing 200,000 tons of $4.50 material at the Eureka Hill has been leased to the Knight-Dern interests.

Salt Lake County

Large companies are said to be increasing their holdings in the Bingham district.

The Cardiff company is shipping from 125 to 150 tons of ore per day, yielding $30 per ton net at the smelter. A dividend of 50c. per share is expected for Christmas. About 100 men are employed.

The Pittsburg Consolidated Mining & Milling Co. is driving a 1200-ft. tunnel to connect the Little Cottonwood and American Fork sides of the divide. Sixteen men are employed.

Summit County

During the past three months the Silver King Consolidated made a profit of $188,000.

Tooele County

A large adit is proposed to drain and develop the Sharp claims in this county. Thirty carloads of ore have been shipped during the past two years from one shoot.

WASHINGTON

Ferry County

Ore shipments are to commence from the Laurier mine at Laurier, 12 miles south of Grand Forks, B. C. This property was located in 1896, and has had a varied history. As the adit is on a steep mountain, a 2100-ft. tramway was constructed to the railroad. The newer workings show 6% copper, 6-oz. silver, and $1.50 gold ore.

Stevens County

(Special Correspondence.)—The Mayflower mine, Chewelah district, is reported to be showing nine feet of ore at a depth of 50 ft., assaying $50 in gold and silver. It has been bonded to J. W. Douglas, who is associated with Volney D. Williamson in its development.

The president of the United Copper Co., Conrad Wolfle, is reported to have said that the property has been bonded to an Eastern syndicate. The mill is treating about 250 tons of ore daily. About 75 men are employed.

The Electric Point mine, near Northport, with two men, is yielding four tons of galena per day. Boulders of galena weighing over a ton have recently been extracted from this property.

Chewelah, October 15.

CANADA

British Columbia

On October 15 the Standard Silver-Lead company of Silverton declared a dividend of 2½c. per share.——On November 1 the Granby Consolidated will pay $1.50 per share.

The new 100-ton mill at the Galena Farm mine, near the Standard, is ready to operate. Over 35,000 tons of ore has been opened in the mine, which is mainly zinc ore, although lead-silver ore occurs. Concentration will go to Bartlesville, Oklahoma.

Lessees at the H. and E. zinc mine in the Salmo district shipped 71 cars of ore from March 1 to September 3, and will make a profit of $55,000. Spokane people have now leased the property.

According to F. R. Wolfle, general manager of the Florence company, operating near Ainsworth, a hydro-electric plant, compressor, and 200-ton mill, together with development, are to be installed at a cost of $150,000. A 4000-ft. adit is part of the development. Lead-silver-zinc ore is mined. The Highland mill of 100-ton capacity, 1¾ miles from the mine, is to be used in the meantime.

Manitoba

Gold has been discovered by D. Mosher and J. Hammell, 10 miles from Athapapuskow lake, north of The Pas. An extensive vein of high-grade sulphide ore is said to have been discovered. The district around The Pas was described in the Press of June 19.

Ontario

During September the high and low-grade mills of the Nipissing treated 76 and 6691 tons of ore respectively, yielding a total of $178,484, $58,610 from the former and $119,874 from the latter. Shipments of bullion from all sources amounted to $120,976. The usual amount of development was done.

The Kerr Lake Mining Co. reports as follows for the year ended August 31, 1915: silver production, 2,036,963 oz.; revenue from ore, etc., $908,018 (decrease of $67,868); cost of production, $357,243; balance, $550,775; dividends, $620,000; deficit, $69,225; previous surplus, $961,093; present surplus, $891,868. Cost of mining was reduced from $5.09 to $4.15 per ton. Prospects of opening new ore are not considered bright. Reserves are estimated to contain 1,526,300 oz. less than before, the total contents being 4,172,400 ounces.

KOREA

The Seoul Mining Co. operating the Suan concession in Whang Hai province, reports the following results for September at the Suan mill:

Ore treated, tons	7,520
Mill worked, days	27
Recovery, bullion	$38,750
Recovery, concentrates	19,965
Total	$58,715
Operating expenses	$27,500
Net earnings	$31,215

The new 400-ton mill at Tul Mi Chung mine commenced full operations on September 30 and is working smoothly.

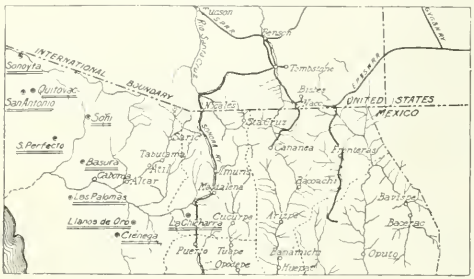
MEXICO

On October 13 Villa issued a decree ordering the American Smelting & Refining Co. to resume at its mines and smelters in the Chihuahua and Santa Eulalia districts by the 15th, or he would seize and operate them himself. Work was suspended at these properties several weeks ago, causing many unemployed. This probably vexed Villa, resulting in the threat.

Officials of the American Smelting & Refining Co. consider it too early to forecast results of the proposed recognition of Carranza by the A. B. C. powers and the United States. At present the company is doing nothing in Mexico. All American employees have been withdrawn, and in many cases plants are in charge of Mexicans. For the past two years full Mexican operations have not been attempted, there being only in-

termittent attempts to operate the various properties. Despite the long idleness, and the violence that has reigned, the plants have suffered little damage, and it is stated that claims against the Carranza government will probably not total more than $200,000. The various factions have shown no hostility against the company.

The principal problem confronting the company and all other American enterprises in Mexico, is transportation. For



ALONG THE INTERNATIONAL BOUNDARY.

three years no work has been done on Mexican railways, and tracks, rolling stock, culverts, and equipment are 'shot to pieces.' Many million dollars and a considerable period will be required to bring the roads to efficiency.

The A. S. & R. Co. has five smelters and about 30 mines in Mexico. Three of the smelters, in the south, are under control of the Carranzistas, while the two northern plants are in Villa territory. It is hoped Carranza will be able to consolidate this control over southern territory at least, and when this is done, attempt may be made to resume operations there, provided other conditions make it possible. The company has been careful to take no part in the struggle in Mexico, and has had no trouble from either faction.

The Southern Pacific Railroad Co. of Mexico, according to a reported statement made by Epes Randolph, its president, will present a bill of damages of $12,500,000 to the first stabilized Mexican government. He also said that when satisfactory political conditions obtain in Mexico the company will extend its railroad, now connecting Nogales with Guadalajara, 350 miles southward to Mexico City.

Sonora

At the Greene-Cananea two reverberatory and four blast-furnaces, and the mill are in operation. A flotation plant is being added to the latter. The September output was 3,514,000 lb. copper, 952 oz. gold, and 148,603 oz. silver, all considerable increases.

On account of the threatened trouble by Villa's army, the Moctezuma Copper Co. has ordered all its foreign employees to leave Nacozari. Calles states that he can easily defend Agna Prieta. El Tigre has not closed yet, and J. D. Malcolmson says that they will operate as long as possible, but bullion and stores have been sent to the border.

The better outlook in Mexico will also help greatly the United States Smelting, Refining & Mining Co., whose Real del Monte silver mines at Pachuca are only at 70% capacity. The Mexican employees have been loyal to the company. A shortage of lime has hindered ore treatment.

On October 9 the Montana section of the A. I. M. E. held its first dinner this season. The mineralization of the Boulder batholith was discussed by J. A. Grimes, of the Anaconda company, it being a continuation of the original paper by Paul Billingsley. This intrusion covers 70 mining districts and includes over 700 mines.

PERSONAL

Gardner Williams is on his way back to Washington.

George V. Mitchell has left London, going to Petrograd.

D. C. Bard has returned to Butte from British Columbia.

Courtenay De Kalb is returning to Tucson from New York.

Lewis Hind, of Hind & Johnson, at Oatman, was here last week.

F. Lynwood Garrison has returned to Philadelphia from Arizona.

C. C. Broadwater is now spending much of his time at Park City, Utah.

S. F. Shaw is now at the Dairy Farm mine, near Trent, California.

John M. Nicol has returned to San Francisco from Lewiston, in Trinity county.

Leo Von Rosenberg is examining mines in the Mother Lode region, California.

D'Arcy Weatherbe is sailing from New York by the *Rotterdam* on October 30.

Charles A. Banks, of the Jewel mine, British Columbia, is examining mines in Washington.

I. L. Fulton has returned from Willow Creek, Alaska, on his way home to Portland, Indiana.

N. Dickerman, general manager for the Pato Mines (Colombia) Ltd., is expected in San Francisco.

Charles T. Hutchinson, the business manager of the Mining and Scientific Press is visiting Denver, Chicago, and New York.

G. C. Bateman has resigned from the Canadian Mining & Exploration Co. to become field engineer to the La Rose Consolidated, at Cobalt.

F. Fukeda, mining engineer, with the Mitsu Bishi Co., is visiting the metallurgical works near San Francisco, preparatory to returning to Japan.

James C. Roberts, recently with the Bureau of Mines, has been appointed to the Joseph A. Holmes professorship of safety and efficiency engineering in the Colorado School of Mines.

Robert Marsh has been appointed general superintendent of the Nevada Consolidated copper mines, near Ely, Nevada. He was previously superintendent of the Braden mine, in Chile.

Louis Coderre, the Canadian Secretary of State, and head of the Department of Mines, has resigned to accept a judgeship, and is succeeded by Pierre Blondin, formerly Minister of Inland Revenue.

Thomas M. Skinner, Jr., has completed the chemical work pertaining to the waters of Owens lake, California, and has returned to Colorado where he is engaged temporarily with the Empire Zinc Company.

Obituary

Howard E. Burtin, president of the Western Zinc Oxide Co. and a prominent and respected assayer since 1890 at Leadville, Colorado, died on October 16 at Glenwood Springs, following five days' illness with pneumonia. Mr. Burtin went to Leadville in 1890 as assayer for the Elgin smelter.

Dennis Sullivan died at Denver, Colorado, October 10. He was well known in the West and had long been a business associate of Grant Schley in British Columbian and Mexican mines. He was also a heavy investor in the utilities companies of Henry L. Doherty & Co. and in other enterprises. Originally he mined in Gilpin county, Colorado, where he made his first stake, moving then to Denver, where he became profitably interested in public utilities. He was a shrewd but kindly man, and his death will be widely regretted.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, October 21.

Antimony	32
Electrolytic copper	19
Pig lead	5.00— 5.95
Quicksilver (per flask)	$92
Spelter	16
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	26

ORE PRICES

Antimony: market weaker, 50% product, free from deleterious impurities, per unit.....$1.40

Tungsten: depending on quality, subject to negotiation, minimum 65% WO_3, per unit for spot.....30.00

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, October 21.—Copper is quiet and weak, with a tendency to go lower; lead is very strong, with a strong demand for export; spelter has hardened considerably, spot is scarce.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

The silver market is steady, with apparently a good undertone.

Pixley & Abell, London, state that offerings continue to be on a limited scale, while the chief support is for English coinage. The Continent has also contributed to the steadiness of the market. Both India and China seem disinterested as far as London is concerned, but the steadiness of China Exchanges is noticeable. As regards the Indian Bazaars, it seems probable that their present stocks will be sufficient for a while. In the immediate future the market may have to depend on the continuance of the present buying and may therefore be a little uncertain from day to day, but, so long as the offerings do not substantially increase, much change is not looked for.

Samuel Montagu & Co. consider that the general position is not unfavorable. The temporary cessation of purchase by the United States Mint may create dullness, but the feeling that there will be probable further purchases should maintain a good undertone. The withdrawal of gold from circulation, not only in England, but also in other countries, is good for silver, as there exists among some people an undoubted preference for silver coin over notes of low denomination.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	13.60	19.75	Dec.	12.75	....

Exports during the week ended October 2 totaled 16,189,622 lb., valued at $2,965,857, 7,628,452 going to Russia, 4,686,763 to England, 2,576,804 to Italy, and 1,402,623 to France. Imports of all kinds amounted to 13459,307 lb., worth $2,131,339. Chile contributed 4,238,692; Canada, 2,145,644; Cuba, 1,982,400; Japan, 1,490,517; Spain, 1,317,678; and Peru, 806,402 pounds.

A good deal of Lake copper has been sold by a leading producer at 17.87c. per pound. Ahmeek has declared $2.50, and Osceola $3 per share.

The Granby output in August was 4,047,421 pounds.

Tennessee is to issue $3,000,000 first mortgage 10-year convertible 6% bonds. The company's capital has been increased from $5,000,000 to $6,875,000.

Copper shipments from Alaska for seven months totaled 32,880,582 lb., worth $5,635,258, against 12,819,459, valued at $1,902,281 in this period of 1914.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

The New Jersey Zinc Co. has declared an extra dividend of $2 per share on the new capital of $35,000,000. On August 10 the quarterly of $2.50 was paid.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Tin is quiet at 33.25 to 33.50 cents.

Eastern Metal Market

New York, October 15.

Copper, zinc, and lead have been disappointingly dull, and all show a tendency toward lower prices, such as is developed by pressure to sell. It is highly probable that quotations will drop a few points, at least, before buying ensues. The zinc market has been ragged both here and abroad, though there still exists the shortage of spot metal. The only feature in lead consists of some good export sales. Attention has been attracted to tin by the expectation that Great Britain will impose a duty on its exportation; a tax which the consumer must pay. Antimony is strengthened by the closing of the Panama Canal, and the interruption to traffic from the Far East. Aluminum, closely held and keenly sought for, has mounted to 55 to 60c. in ton lots.

The response of sterling exchange to the completion of the $500,000,000 Anglo-French loan has been disappointing. The rate has continued to improve and $4.68 was quoted on October 14. This compares with $4.50 on September 1, but a higher figure was expected.

The iron and steel trade shares none of the dullness witnessed in metals; on the contrary, the steel mills are struggling to make deliveries. The unfilled orders of the United States Steel Corporation showed a total of 5,317,618 tons, September 30, an increase of 409,163 tons, compared with August 31. On September 30, 1914, the unfilled orders amounted to 3,787,667 tons. The exports of iron and steel totaled 401,298 gross tons in August, 1915, against 86,598 tons in August, 1914. In eight months of this year they totaled 2,077,783 tons, against 1,046,347 tons in the same period of 1914. Exports of machinery and munitions are correspondingly large. Semi-finished steel is scarce and brings premiums. Plates, shapes, and bars are quoted at 1.40c., but a higher price is frequently paid, and the mills are unwilling to contract into 1916 at this figure.

COPPER

After remaining at the 18c. level for nearly three weeks, copper shows signs of weakening, and it is highly probable that a firm offer of 17.75c., cash, New York, would be accepted. Since the large export buying of over two weeks ago, the market has been flat, and in the absence of business quotations are practically nominal. Lake commands no premium over electrolytic. The London market in Standard copper is considerably weaker than it has been, but the metal itself has been steady at £88, the explanation being that American producers control electrolytic. Exports from October 1 to 16 total only 9913 tons. Following is a comparative statement of copper exports in long tons, from the United States during nine months of this year, as compiled by C. Mayer, secretary of the New York Metal Exchange:

	1915.	1914.
United Kingdom	60,458	63,498
France	68,915	48,530
Germany	.....	88,452
Holland	947	57,085
Belgium	.....	2,876
Austria	.....	13,809
Italy	31,415	11,995
Denmark	1,711	.....
Norway and Sweden	12,134	.....
Russia	9,171	125
China and Japan	108	1,640
Sundries	1,804	4,757
Total	186,663	292,767

In purchasing 3700 lb. of sheet copper, annealed, the Government Arsenal at Frankford, Pennsylvania, accepted the American Brass Co.'s bid of 21.25c. per pound.

ZINC

Continued lack of interest on the part of consumers has developed a weaker market, with considerable pressure to sell for delivery this month, although spot metal is still reported scarce. Prompt deliveries were offered October 15 at 13.25c., New York, and 13c., St. Louis. Shipments to the end of the year grade down to 11c., New York, and contracts for delivery in 1916 could easily be made at this price. The London market has also been weak, and on October 11 declined £3 10s. On the 13th it dropped another £1 5s. It is plain that at present prices galvanizers are not buying spelter, a fact which is reflected in the low state of activity of the galvanized-sheet trade. Exports continue at a good rate, those of the first 15 days of October aggregating 2295 tons.

Sheet zinc is unchanged at 16c., f.o.b. smelter, subject to a discount of 8% on cash for carload lots.

LEAD

Some good export orders have been booked, but otherwise the market has been quiet. The quotation of the A. S. & R. Co. has been steady at 4.50c., New York. The St. Louis quotation has been 4.42½c., but independent sellers are beginning to show a disposition to shade the Western price. At New York they have been content to meet the quotation of the largest interest, but at some other points they have undersold to a slight extent. Altogether the market has been uninteresting. Exports from October 1 to 16 totaled 1226 tons.

TIN

All interest in the tin market is centred in the continued idea that Great Britain will impose a 10% export duty on the metal, a report so seriously regarded by the board of managers of the New York Metal Exchange that it held a meeting on October 8, and adopted the following:

Whereas, it is reported that the question of levying an export duty on tin is now under consideration by the British authorities, the board of managers of the New York Metal Exchange declare:

That the provisions of the New York Tin Contract as adopted by the New York Metal Exchange, and the Rules of the Exchange, make it sufficiently clear and explicit that, in the event of such a duty being levied, it must be paid by the buyer unless otherwise specifically agreed.

Inasmuch as a fair number of contracts now operative have several months to run, it will be seen that the imposition of a duty will prove a serious matter for consumers, and many of them already have made protest based on a different construction of the rules of the Exchange. The situation has killed all business in futures. The only trading in recent days has been in spot and near-by deliveries, and there has not been much of this. There is a large stock of tin now in this country which would not be subjected to the tax, and should Great Britain make the expected announcement there will be a scramble for it. Arrivals this month amounted to 1675 tons, and there is afloat 4225 tons. Since October 1, the price has hovered between 32 and 32.87½c., touching the higher quotation on the 14th.

ANTIMONY

The blocking of the Panama Canal, holding up a large number of ships, acted quickly as a bull influence in the antimony market, and Chinese and Japanese became stronger, advancing to 28.50 to 28.75c., duty paid. Domestic antimony is offered at about the same figures. A special cable to the New York Metal Exchange on October 13 stated that the nominal price of Hallett's at London was £100 per ton (24c. per lb.), a quotation which had prevailed for some weeks.

COMPANY REPORTS

CONSOLIDATED INTERSTATE-CALLAHAN MINING CO.

The third annual report of this, said to be the third largest zinc-producing company in the world, covers the year ended June 30, 1915. The mine and mill are in the Nine-Mile district, Coeur d'Alene, Idaho, and the output and profits during the past year have attracted much attention. The president and general manager is John H. Robbers, of Spokane; mine superintendent, C. W. Newton; and consulting engineer, D. F. Haley. The previous year's operation left a loss of $99,314, but the last year allowed of $697,597 being paid in dividends, and made a surplus of $1,094,862 at June 30.

Development during the past six months totaled 1510 ft., also 11,856 cu. ft. of stations and skip-chutes. No. 4 shaft was sunk 25 ft. to a depth of 485 ft. On July 1 there was blocked out above No. 6 level ore enough to supply the mill for 4 years.

Sales of products during the year were as follows: lead ore, 246 tons; lead concentrate, 2563 tons; zinc ore, 8473 tons; and zinc concentrate, 30,681 tons. The revenue from these totaled $2,146,283. All expenditure, including $79,550 on improvements, amounted to $569,404. From the profit of $1,591,773 the sum of $697,597 was paid in dividends. Assets total $1,151,642, and liabilities $56,780. The company's capital is 500,000 shares at $10 each, now standing at $21.

The mill has been re-modeled to treat 10,000 tons of ore per month. Flotation is used to aid recovery.

ORIENTAL CONSOLIDATED MINING CO.

The report of this well-known company, operating in Korea, covers the year ended June 30, 1915. The report is very complete, being 40 pages in length.

Nine mines were worked, all producing ore for the five mills. Development amounted to 37,214 ft., also 4532 ft. in prospecting on other claims, a total increase of 6819 ft. over that of 1913-14. Reserves are as follows:

Mine.	Tons.	Average value.
Tabowie to No. 15 level	550,000	$6.13
Taracol to No. 9 level	205,000	4.01
Chintui to No. 8 level	20,000	3.50
Kuk San Dong mines (3)	12,790	3.70
Charabowie to No. 12 level	45,000	9.27
East Candlestick	4,000	9.00
Tongkol	10,000	8.00

Results of development at the Tabowie, Chintui, and Charabowie were very good, at Taracol and East Candlestick were discouraging, while the Kuk San Dong mines were worked out.

The five mills with a total of 250 stamps crushed 297,889 tons in 230.42 days, averaging $6.55 per ton, yielding bullion worth $981,747. There was 33,177 tons of concentrate saved, yielding $643,571.

The total value of bullion recovered was $1,625,318; operating charges were $919,982 or $3.09 per ton; and construction, development, etc., $92,409; leaving a net profit of $660,095. Dividends amounted to $858,780, the excess over the profit being drawn from cash on hand, which now amounts to $447,018.

The Central American Mines, Ltd., of London, has issued a report covering the period from November 20, 1913, to December 31, 1914. The property is in Nicaragua. The output of gold and silver was worth $183,000. The 20-stamp mill only worked 56% of the time owing to power and treatment troubles. Costs were $7.32 per ton, but are now $5.32. Development was good, and large profits are soon expected.

BOOK REVIEWS

Handbook of Mathematics for Engineers. By L. A. Waterbury. Second edition. P. 213. Ill., index. John Wiley & Sons., Inc., New York. For sale by the Mining and Scientific Press. Price, $1.50.

The present edition is a few pages larger than the previous one, but errors have been corrected, and revisions made. New and important additions deal with hydraulics and reinforced concrete. The book, which is of vest-pocket size, is intended for reference, not for a text-book. Subjects are grouped under algebra, trigonometry, analytic geometry, differential calculus, integral calculus, theoretical, mechanics, mechanics of materials, hydraulics, and 105 pages of logarithm tables, etc.

Practical Surveying. By Ernest McCullough. D. Van Nostrand Co., New York. P. 395. Ill., index. For sale by Mining and Scientific Press, San Francisco. Price, $2.

There are many books on elementary surveying published every year. Usually they cover the subject fairly well and are much alike. The present volume differs from the general type in a few particulars. Important among these is a much fuller discussion of the retracement of old surveys than is usually found. This is commendable. Against this, may be set the fact that the mathematical tables are sprinkled through the book instead of being collected in a convenient place at either the front or the back of the volume. Also the work is not pocket-book size, and is bound in material that would not stand field usage. In fact, while the volume is a fair text-book, it is entirely unsuited for use in the field. A curious feature of the book is a short appendix on algebra.

Steam-Boiler Economy. By William Kent. John Wiley & Sons, New York. P. 709. Ill., index. For sale by Mining and Scientific Press, San Francisco. Price, $4.50.

Considerable attention has been directed to the fact that while there are a number of exhibits of internal-combustion engines at the Panama-Pacific Exposition, practically no attention has been paid to steam-engines. It has been suggested that while the internal-combustion engine is still in its infancy and new discoveries are being made every day, the steam-engine has become practically standardized and there are few new developments that are worth exhibiting. So, in the fourteen years since the first edition of this standard work appeared, there have been no remarkable developments in either the use or the design of steam-boilers, but there has been sufficient progress in details to justify a second edition. Greater efficiencies as well as higher duties are obtained than were the rule fourteen years ago, and the principal changes from the first edition deal with progress along these lines. Considerably more space is also devoted to oil as a fuel than in the former edition, although there are some statements as to the limitations of this use of petroleum that are more correct for the Eastern than for the Pacific Coast or Gulf States.

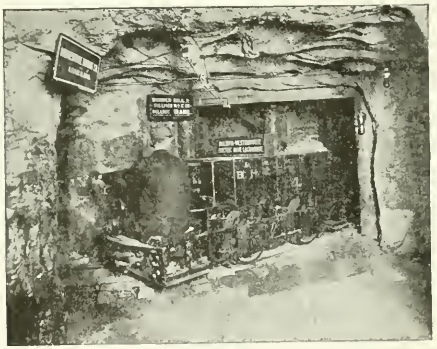
The general chemical and physical facts of combustion are first discussed and then the properties of different kinds of fuel. The next chapter is devoted to furnaces, methods of firing, and mechanical stokers. Boilers are then considered, from the plain cylindrical boiler up to the more modern types. Boiler-design and accessories to boilers are then taken up, and boiler-troubles. Methods and results of steam-boiler trials are discussed, and then the properties of steam and the design of chimneys. The last chapter is devoted to miscellaneous subjects. Perhaps the best way to describe the book is to say that it is as comprehensive for the present time as was the first edition, for the period when it appeared.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Electric Locomotives at the Exposition

The Mine in the Palace of Mines and Metallurgy has been described in the PRESS of May 1, 1915, also in several other issues. The absence of the mule is noticeable in this modern mine. In his place the visitor is shown the simple and efficient electric mine locomotive. There are two of these 'electric mules' shown, one in the metal section, of the storage-battery type 24-in. gauge, and the one in the coal section which is 42-in. gauge, and of the trolley, gathering-reel type. Both locomotives are of the well-known bar-steel frame construction of Baldwin-Westinghouse manufacture. The gathering-reel locomotive is of five-ton capacity, having two No. 903 motors for 250-volt service, and operates by means of the gathering reel in and out through a pair of automatic opening doors with a load of coal. This reel automatically pays out the cable on the outbound trip, and gathers it up on the return. The Westinghouse Electric & Mfg. Co., East Pittsburg, Pennsylvania, supplied all the motors used in the mine.



ELECTRIC LOCOMOTIVE UNDERGROUND.

Pumps at the Exposition

The large exhibit of the Krogh Pump Manufacturing Co., San Francisco, in the Palace of Machinery at the Exposition is attracting considerable attention. It consists of a varied line of centrifugal and turbine pumps of the most modern design. The principal exhibits are as follows:

One two-inch single-stage centrifugal pump direct connected to a 5-hp. motor, running at 1800 r.p.m. This pump has a capacity of 100 gal. per minute against a pumping head of 95 ft. It is set on four 1¼ in. steel balls on an ordinary wooden table, and special attention is drawn to the fact that this unit is not bolted down to any foundation, yet when working no vibration is perceptable, even though operated against a closed discharge. The Krogh automatic balancing arrangement, as embodied in all designs of Krogh centrifugal and turbine pumps, is absolutely fool-proof, needing no adjustment whatever, no matter what the condition of suction or discharge, and no set-collars or thrust-bearings are required.

Other pumps in operation are the Krogh deep well turbine of the regular and combination types. The particular features of these are that the rotating parts are carried by the automatic hydraulic water-balance, without the use of the usual heavy thrust-bearing at the top.

Another type that arouses interest is shown in the small vertical submerged type sump pump which is entirely automatic in operation.

The mining features of this exhibit are strikingly shown in the Krogh motor-driven sinking and station-pumps, Cornish and jack-head pumps, and the well-known Krogh slime and tailing pumps, all of which are well spoken of by large mining companies.

The exhibit is very complete, as it includes pumps from 26-in. size, with a capacity of 25,000 gal., down to those of about 10 gal. per minute, and for such varied uses as reclamation, drainage, fire-pressure systems, city sewerage, irrigating, mining and sugar factory work. The Exposition Jury awarded Krogh pumps several gold medals. The Exposition grounds and buildings get their entire water supply through Krogh pumps.

Commercial Paragraphs

The C. O. BARTLETT & SNOW CO., Cleveland, Ohio, has issued Bulletins 41 and 43. These deal with coal tipples and mining plants, and the Cabasco system of handling materials. The machinery is strong and of good material.

Bulletins 150, 151, 152, 153, 154, 300, and 104 of the A. S. CAMERON STEAM PUMP WORKS, New York, describe and illustrate ordinary, turbine, triplex, and other pumps manufactured for all purposes. They are all suitable for mine and mill work.

The CHICAGO PNEUMATIC TOOL CO. is distributing its Bulletin No. 216, covering its Hummer self-rotating type hammer-drills, which are made in three sizes, known as the A-66, B-66, and C-66 drills, suitable for drilling 6, 8, and 12 ft. holes respectively. Among the important features which the manufacturers have incorporated in their drill is that of the rotation of the steel being entirely independent of the hammer piston, eliminating the use of ratchet or pawl parts; and the valve which consists of a standard commercial hardened steel ball ordinarily used for ball-bearings. It is ⅝-in. diameter, and gives complete satisfaction. The firm has also issued *Booklet* No. 213, describing the new 'Simplate' flat-disc valve. It is simple, having independent plates and springs, the action being ideal under all speed conditions.

The Akins classifier is described in Pamphlet No. 24-B of the COLORADO IRON WORKS CO., Denver. This machine is giving satisfaction at about 40 large mills in this country. It consists of a trough, which is set at an inclination downward toward the slime-discharge, enclosing a revolving spiral or screw. The spiral is gear-driven at from 3 to 5 r.p.m. By the action of the screw the heavier particles of pulp settle to the bottom of the trough, and are gradually conveyed to the top end of the machine for discharge into a launder, etc., to be returned to a tube-mill or other part of the plant. The classifier is operated in closed-circuit with a ball or tube-mill. A 45-in. machine is handling 355.4 tons of pulp per day, containing 147.5 tons of solids. Moisture of the sand discharge is 22.7%, and 77.7% in the overflow, which contained slime 62.8% of which passed 200-mesh for flotation treatment. A lot of interesting matter is given in this publication.

EDITORIAL

T. A. RICKARD - Editor

MINING is essentially speculative, but it is a sane speculation, not like the gambling in war-stocks.

FUNDAMENTAL business conditions are better now than at any time since 1912. The revival of industry continues to spread. And yet the factor of abnormality, in so far as the War has stimulated certain manufactures unduly, must not be ignored.

WHEN Mexico is put in order and re-opened to peaceful industry, it will be a great day for the mining profession. There is now so much money available for new business in America that there would be no difficulty in financing fresh enterprises or resuming mining and smelting operations on a generous scale.

IN the latest circular of the Mining and Metallurgical Society it is stated, by the secretary of the New York section, that the MINING AND SCIENTIFIC PRESS re-published in full the remarks made by Mr. J. R. Finlay on 'Industrial Efficiency as a Military Weapon.' Not only did we not do so, but we stated explicitly, in our issue of August 14, that, owing to prejudices arising from the War, we deemed it unwise to discuss the problem. We learn from New York that the error was quite inadvertent and that our Denver contemporary, now deceased, was the periodical to which reference should have been made in regard to the re-publication.

VARIOUS estimates have been made of the amount of copper used in cartridges by the hosts of the belligerents; one is that if 8,000,000 soldiers are in the field, each with 400 cartridges, they would account for 44,800 tons of copper, which is 25% more than the estimated stock of the metal in Europe on the eve of the War. Including copper in shells, the total amount would be equal to the whole stock available in both Europe and America just before hostilities began. Another estimate places the consumption of copper at the present time on the European battlefields at 230,000 tons per annum or about 20% of the world's total production.

RAY and its copper is discussed in an interesting letter contributed to this issue by Mr. Frank H. Probert. The question of valuing these copper mines in Arizona is timely, having regard to the incorporation and flotation of another enterprise in the same district, namely, the Ray Hercules Copper Company, which now controls the Arizona Hercules property, belonging formerly to Mr. W. P. Dunham. The orebody has been drilled at intervals of 100 feet, disclosing 3,400,000 tons of 2.36% copper ore in an area of 13½ acres, out of 207 acres owned by the company. This appears to negative a geologic forecast, for Mr. J. E. Spurr insisted that no ore would be found west of the Ray fault. That, however, was at a date when all the necessary evidence may not have been available. Three-quarters of the Ray-Hercules ore is in diabase, in ground so wet as to handicap the application of any ordinary caving system. This fact will test the resources of the capable manager, Mr. C. E. Addams, who was formerly at the De Beers diamond mines at Kimberley, and lately assistant superintendent at the Ray Consolidated. The enterprise starts under good auspices and should prove a notable addition to the disseminated copper mines of the West.

MEXICAN affairs progress slowly. An embargo on the American export of arms and ammunition into Mexico has been put in force as against everybody except the *de facto* Government, the recognition of which has already caused numerous desertions from the Villa forces. It is stated that the corn harvest is 60% short of normal, so that much misery is certain during the coming winter, unless the restoration of order stimulates the importation of food-stuffs. Mexico, of course, is bankrupt. Claims for damages will amount to a colossal sum, hundreds of millions. A commission to inquire into this matter is to be appointed by Carranza. A big bond issue, secured by customs duties and internal taxes, will have to be made as soon as the Government forces have crushed the Villa and Zapata factions. Meanwhile conditions in northern Mexico are more uncomfortable than ever, pending a decisive engagement between Villa's troops and those of the Government. But there is every reason for believing that Villa's adherents will shortly be scattered and that he will seek safety on this side of the Rio Grande. Then we may expect a general revival of mining in the northern region, to be followed by a resumption of activity southward as soon as railroad communication is restored.

IN the Minerals Separation *v.* Miami suit recently it was stated that, besides the Miami, those infringing upon the alleged patent rights of Minerals Separation were the Utah Copper, Nevada Consolidated, Nevada Mining & Smelting, and the Magma Copper companies. This, however, we venture to add, is not a complete list. In the case, now under adjudication, the counsel for the plaintiff asserted that the infringing companies "let $17,000,000 run to waste in one year, 1913, before they knew of our [the M. S.] last invention." He also stated that the extraction by wet concentration was only 63 to 71%, "whereas Anaconda and Inspiration [using M. S. patents] extract 85 to 95% at no greater cost of plant

or of operation." He then proceeded to disclose the terms arranged by Minerals Separation with the Anaconda and Inspiration, namely, that these two companies have guaranteed that if the Supreme Court reverses in the Hyde [or Butte & Superior] case, or if they do not exercise their option to surrender their license in case of affirmance, they will treat 25,000,000 tons of ore by the Minerals Separation process by 1923, and will pay the agreed royalty thereon, this royalty we understand being ⅔ cent per pound of copper, but not less than 12 cents per ton of ore; and meanwhile, whatever the decision of the Supreme Court, they have agreed to pay a royalty of $300,000 to Minerals Separation within a year. Undoubtedly the improved returns at the Miami are due largely to the use of flotation. When the management of the Inspiration had completed plans for the erection of a new wet-concentration mill, it was decided to make some tests in flotation, which was found to promise an extraction at least 10% better. Whereupon an experimental plant was erected and thorough tests made, with the result that the original mill-plans were discarded and a new design involving the use of flotation was adopted. We understand that the extraction in the new mill, using flotation, is fully 15% better than that obtainable by any of the older methods.

OFFICIAL notice has been given that the Australian Metal Exchange was established as from September 6 and all metal-trading with persons outside the Commonwealth must now be conducted through the Exchange, which is under Government control. This is one of the by-products of the War. It is due largely to the disclosures made during the Snow trial. Another illuminating case came recently before the Prize Court in London, when Henry R. Merton & Co. made a claim on the British Government on account of freight paid for a shipment of zinc concentrate from Broken Hill consigned to them by the Australian Metal Company, one of their affiliated concerns, and seized by reason of its enemy destination, namely, the Metallgesellschaft of Frankfort, Beer, Sondheimer & Co. of Frankfort, and Aron Hirsch & Sohn of Halberstadt, all in Germany. In giving judgment, the Court said that the Merton company was intimately associated with the Australian Metal Company and two of the German firms mentioned. Lack of good faith with the British Government was imputed to the Mertons, important letters to these German firms having been withheld, until the office of one of them was raided. The Judge said that their claim "required much assurance, and to persevere in it showed a reckless want of appreciation of the possible consequences. Messrs. Merton & Co. did not hesitate to engage in commercial intercourse with the enemies of this country in their desire to get the goods for an enemy firm." Our readers will learn with amusement that the firm of Henry R. Merton & Co., which includes several British partners—although the name Merton was changed from Cohen—has acted as metal-buyer for the British Admiralty and has been gravely consulted on kindred matters, such as nickel imports. These disclosures confirm the accuracy of our diagnosis of the nexus of metal-selling agencies that has endangered the welfare of the mining industry. Not because it is German, but because it is a combine in restraint of fair trade in the metal-markets of the world, we object to the secret interplays of this international coterie.

CORNISHMEN all over the world will be interested to learn that the Tehidy Estates of Mr. G. L. Basset have been sold to Mr. Hamilton Edwards, formerly manager for the Amalgamated Press. This property embraces the mineral rights to a number of famous Cornish mines, including Dolcoath, Carn Brea & Tincroft, East Pool, and South Crofty. These mines pay 'dues,' or royalties, on their gross output of tin to the 'mineral lord' or land-owner. Dolcoath alone has paid $850,000 in dues to the Basset family during the 19 years of the present company's life. It is announced that the new proprietor is prepared to discuss the compounding of these obligations "on quite moderate and reasonable terms." Another item of interest is the appointment of Mr. Herbert Thomas as mining representative of the new owner. Mr. Thomas is the vivacious and energetic editor of *The Cornish Post;* at one time he was on the staff of the San Francisco *Examiner*, but he has outlived that handicap and become a journalist of high character. Undoubtedly the selection of a man so closely in sympathy with Cornish mining as the agent for the new owner will go far to assure a satisfactory adjustment of a burden that has been felt keenly by the mining companies tributary to the Tehidy estate.

Labor and Capital

In our last issue we made reference to recent strikes, more particularly the one now in progress in Arizona. Such labor disturbances, it may be confessed, often find the members of the mining profession in a difficult position, between the devil and the deep sea. Any thoughtful and observant man cannot help becoming aware that the rights and wrongs of the quarrel are confused. For instance, while it may appear perfectly justifiable for the managements of mines to refuse to negotiate with their employees when the latter have put their case into the hands of an outside organization so stained by crime as the Western Federation, it does not seem reasonable to object either to the formation of a union among the employees or an affiliation of that union with a national organization of the same kind, namely, a legitimate combination for the purpose of collective bargaining. Of course, the mining company itself is a union or combination of owners, the stockholders; moreover, the companies in the same district agree, through their managements, to act as a unit in labor matters and sometimes they extend their co-operation over wider areas. In the big strike at Johannesburg two years ago the refusal, for instance, of the management of the Kleinfontein mine, where the strike began, to deal with any labor representatives not in its employ, was supported by the claim that the Kleinfontein management was acting

alone, without agreement or support from the neighboring companies. That was humbug. The managements of the big groups of mines supported one another loyally and were in close agreement as to their labor policy. Such co-ordination of interest is logical and inevitable. That being so, to attempt at this late date to deny any group of men, laborers or capitalists, the right to combine in legitimate self-protection is futile. Collective bargaining has come to stay; it is one of the results of business expansion, involving large numbers of laborers on one side and large numbers of employers on the other side. The joint-stock company typifies the combination of capital just as the union represents the solidarity of the labor element. Unfortunately, with an increase in the scale of operations has come a loss of personal contact between employer and employee, tending to dehumanize the relationship between them. In both the Michigan and Transvaal strikes one of the complaints was that the bosses subjected the men to petty tyranny and unfair discrimination, sowing the sure seeds of resentment.

Undoubtedly the multitudinous character of modern industry tends to obscure the rights of the individual unless he combines with his fellows, so as to compel consideration from those in authority. On the other hand, the contract between labor and capital, that is, the agreement to abide by fixed terms of employment and payment, is one-sided; capital gives bonds, as it were, for it has property that can be destroyed and a business that can be disintegrated during the period of a long and violent strike; moreover, a company can be sued for infraction of contract and punished for nonperformance by being mulcted in damages; but a labor-union is here today and gone tomorrow, it has no property to stand sponsor for its word, it has a personnel of shifting parts, it gives no security for the fulfilment of its pledges. Hence agreements between managements of companies and masses of employees, especially if the latter be of alien origin and illiterate, as is largely the case in Michigan and Arizona, are of little use in establishing enduring peaceful relations. That consummation would be more likely if the community—by its legislature—insisted on labor organizing itself on permanent lines, with a registered office and financial responsibilities, so that the property rights behind both capital and labor could stand surety for the observance of their mutual agreements. The funds or other property of a union should be as much jeopardized by the breaking of a contract as the funds or other property of the joint-stock company. Of course, the laborer that puts money into the treasury of his union is just as much a capitalist as the stockholder in a mining company. The community should insist that both 'play fair.' If a union breaks its agreement, it should be outlawed; so also a company guilty of similar turpitude should suffer an equal penalty, involving the inability to operate in the State the laws of which it had broken. The community as a whole suffers from the acts of both parties in these industrial quarrels and it should see to it that both behave themselves.

Behind all this we come to the basic fallacy of the labor propaganda. Of course, labor has a right to combine for self-protection. Every thoughtful man must concede that. But the next most important tenet of unionism, that men shall receive an equal wage irrespective of individual efficiency, is contrary to economic justice. The day's pay system, with a minimum wage that is nearly a maximum, is grossly unfair to the employer, particularly when accompanied by a persistent effort to reduce the hours of work. If all men worked steadily and honestly, eight hours would be enough, and more than enough in some kinds of employment, but the insistence on paying the same wages to all laborers regardless of their efficiency, to the man who really works eight hours and to the man who wastes two hours out of the eight in one way or another, is unfair; it is an economic wrong, just as much, for example, as the attempt to perpetuate a scale of wages irrespective of a change in the cost of living. An escape from the anomalies and stupidities of day's pay is always open by recourse to the contract system, whereby a man is paid in accordance with his accomplishment. But systems of working on contract can be abused like any other; to be successful it is essential that the manager or superintendent shall not try to take advantage of his men. And that, after all, is the crux of the whole matter. It is the effort to impose upon one another that upsets the delicate relation of employer and employee. That relation becomes more delicate as men gain intelligence and initiative. A native-born American makes a poor valet; a democrat makes an unquiet serf. Some men must work with their heads, and others with their hands; so long as one man hardly knows his right from his left, while another can orient himself wherever he may be, so long "witless will serve his master"; but the relationship can be made endurable for both and beneficial to the social organism if mutual consideration is united to a sense of fair play.

Who Owns A Report?

A recent episode provokes an enquiry into the ownership of reports on mines and the delicate questions of conduct in the giving of information obtained by an engineer in the course of examining a mine for a client. Let us state the case. An engineer is retained by a client to examine a mine and to report thereon, with particular reference to the purchase or sale of the property for a stipulated sum. The report is duly made and transmitted to the client. Does the copyright of that report belong solely to the client? Has the engineer parted with his entire ownership in the report? Can he show it to another client or can he actually sell the report to somebody else? Let us answer some of these preliminary queries, as to which we are largely in agreement, in order to clear the way for some more difficult problems. We take it that the members of the profession will agree that if Mr. Dash retains Mr. Blank to advise him on the sale or purchase of a mine for a given sum, then the advice given by Mr. Blank is confidential. To nobody save Mr. Dash should it be disclosed. It is private business.

Next, the advice in such a case involves the appraisal of a mine at a specified date; that information also is private, and, having been transmitted to Mr. Dash, belongs to him alone. For how long? If Mr. Dash drops the business and is no longer interested in the affair, can Mr. Blank use the information, for instance, in advising another client as to the purchase of this particular mine or of another in the vicinity? How long has Mr. Dash got a copyright on the report and the information therein contained? In perpetuity? Then if Mr. Blank were to report on a mine every time he went to a mining district all the first-hand information in his head would be labelled with the names of his various clients and there would be a water-tight partition between each cerebral record—in short, Mr. Blank would be no better off than if he had water on the brain: his mental equipment would be under a perpetual mortgage. Obviously there must be a limit to the placing of an embargo on the information obtained by an engineer in the course of an examination and given by him in the text of his report.

Our readers may suggest that the opinions expressed in the report, more particularly the actual appraisal, belong to the client but the general information that the engineer may have gathered concerning the mining district, in which the mine is situated, remains at the disposal of the engineer. But some kinds of knowledge, as to faulting, as to the trend of an orebody, as to the treatment of the ore, may be as valuable to the client as the appraisal itself, in case the latter should be a promoter or financier intending to transact business in the same district. If it be granted that all of this also belongs to the client, then again comes the question, until when? Has he a lien on all such knowledge indefinitely, and must the engineer make no use of it during the term of his natural life?

If the client informs the engineer that he has dropped the business, is the engineer free then to use the information, to the point of selling the report to another client? Does the fee thus obtained, as a result of his first client's retainer, belong to the engineer or to the first client or should they divide the proceeds? Suppose, on the other hand, that an engineer is commissioned to make a general inspection of a district, without reference to a particular property, and thus gathers a lot of varied data; is the engineer to be denied the use of them subsequently? If not, what use can he make of them? Can he employ them in advising another client in regard to the district as a whole or in reference to a particular mine? Can he publish an article in a technical journal describing this district and embodying much of the information obtained at the expense of his client? What right has the client to prevent him from taking such advantage of the information, more particularly when the client himself has decided not to act on the report? Can the client play dog-in-the-manger indefinitely? Finally, if an engineer has been in the employ of a mining company, is he entitled to write—not on the affairs of the company itself—but on the technical methods applied in that company's operations, with a view to being useful to the profession and of gaining such personal distinction as comes from writing intelligently on technical matters? Has the company any right to close his mouth or forbid the play of his pen—on non-private aspects of its operations—until the crack of doom? To put it even more bluntly, can a client acquire a prior lien on an engineer's brain by paying him a fee? Is that lien without limit of time? To this we need only give the analogy of the architect. When he prepares plans for a client, he retains the copyright. The client has the use of the plans, for a fee, but he does not buy the sole copyright to them, they remain the property of the architect. The latter will not build a second house just like the one shown in the plans and the client is not supposed to sell those plans to a second man. Similarly the lawyer regards his brief, in so far as it concerns his client's personal affairs, as private, but he deems himself free to quote or to publish such portions of the brief as deal with general principles of law and citations pertinent to a subsequent case. Sundry conventions exist in such matters, and beyond the conventions come ideas based on fairness and reasonableness, culminating in that indefinable regard for the eternal proprieties called good taste.

We leave these delicate problems with our readers, hoping that some of them will express their opinions. This is a matter of professional conduct, not to be regulated by any law or regulation. It will be well to elicit the considered opinion of the profession as a guide for those who may be uncertain what course to pursue. We shall be glad to hear from the older practitioners with experience in such matters. We invite the younger men also to have their say. In such matters the young are apt to have clear perceptions. As men grow older their sense of propriety may become calloused; in the rough and tumble of the hard arena of financial conflict, the man that 'puts it over the other fellow' is forgiven for many things that a healthy-minded young man would disdain and condemn. Success excuses much that is despicable. The 'double-cross' is overlooked if it spells a fortune. For these reasons we would like to hear from the younger men, with ideals not yet blunted by greed, with a code of conduct not yet shattered by an unscrupulous ambition. Yet we recognize that the decisive opinions must come from those who have faced the problem in the course of their work as consulting engineers. A report on the facts of life is needed. No laws regulate these matters; they are left to the correction of events. If an engineer outrages the feelings of a client, and the client is deemed not unreasonable by fair-minded men, then the engineer suffers in his practice. If an engineer with a reputation yet to make interferes with a powerful promoter's scheme, the enmity of the latter may prove a serious factor. Unscrupulous financiers and domineering operators can make it hard even for a well-intentioned and straight-dealing practitioner not financially independent. Such brutalities cannot be wholly checked, but the crystallization of a healthy public opinion can do a great deal to regularize these questions of conduct. Before opinion can be crystallized, it must go into solution. Let it be dissolved in common sense and that uncommon sense—the sense of honor.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Valuation of Metal Mines

The Editor:

Sir—At the recent meeting of the International Engineering Congress held in San Francisco, several important papers were presented dealing with the valuation of mineral lands. These should have provoked a lively discussion, but whether on account of small attendance, reticence on the part of those competent to express opinions, or lack of time owing to the necessity of closing the session to attend other meetings, the most valuable contributions to the proceedings were read by title or summarily dismissed in the briefest abstract.

Mr. T. A. Rickard's paper on 'The Valuation of Metal Mines' outlined the methods of appraisal of mines for taxation, citing the very satisfactory work of Mr. J. R. Finlay in the Lake Superior copper and iron districts and Mr. W. L. Uglow's later assessment value of the Wisconsin zinc mines, which apparently lacks in any substantial premise.

Mine taxation has been the cause of much wrangling between State officials and mine-owners in Arizona, although Mr. T. E. Campbell, the State Tax Commissioner, is exercising every effort to formulate a just plan on which mines shall be taxed. The ways and means of the several State tax commissioners should prove of value to those of your readers who are interested in mine valuation.

The mining of large orebodies and the beneficiating of contained metals is just as much a manufacturing business and subject to the same laws as govern other commercial enterprises. The raw material can be definitely appraised, all steps to the finished product analyzed to ascertain an average cost of production of the saleable goods; market conditions, cost of plant, capitalization of the company, life and amortization, all these factors may be determined with a degree of accuracy such as to reduce the purely speculative side of mining to a minimum. The days of the old mine promoter are numbered; capital is interested in the measurable masses of a commercially mineralized deposit rather than in the phantom profits of glaring prospectuses.

In the April 1914 issue of the *Mining Magazine*, attention was called to the tendency of the times in the consolidation of properties and management by the successful few. Of recent years the Utah Copper has absorbed the Boston Consolidated and merged with the Nevada Consolidated; Inspiration and Live Oak have been linked into the Inspiration Consolidated; Ray Consolidated and Ray Central have been joined; the Calumet & Hecla has taken over a number of subsidiary companies and more recently Amalgamated and Anaconda were put together. These transactions were not conducted as cash sales but by re-organization, the issuance of new stock and absorption on the basis of relative values.

To arrive at the relative value of properties under like conditions in the same district, for purposes of consolidation, is a branch of the subject of valuation seldom discussed; the shareholders are advised of the ratio of exchange offered without knowing how the figures were obtained, with the inevitable result that minority interests are often disgruntled and air their supposed grievances in the courts, or temporarily delay progress by recourse to any of the thousand and one legal demurrers at their command.

There are many factors in the equation and no general algebraic formula can be given applicable to all cases. Every mine, like every human unit, has its idiosyncracies; every district its peculiarities. An intimate knowledge of local conditions is requisite. An experienced engineer will weigh carefully all the evidence before figuring. Consolidation may be deemed advisable for many reasons, such as, control of territory, increased tonnage, better facilities for operating, unification of systems, avoidance of litigation, maximum output at minimum cost, reduction of taxes, desirable mixture of ores for smelting, lessening of overhead expense, etc., etc. The object sought will determine the method of procedure. A concrete case of relative valuation merits description.

In 1907 the Ray Consolidated Copper Co. was organized with 600,000 shares, par value $10, to take over the properties of the defunct English company, at Ray, in Pinal county, Arizona. In 1910 it absorbed its younger neighbor, the Gila Copper Co., on a basis of a 1:3 exchange of stock, increasing its capitalization to $14,000,000. In 1912 still another re-organization was effected by the acquisition of the Ray Central Copper Mining Co. at the ratio of 1:8 and the issuance of an additional 200,000 shares of stock.

Ray Consolidated had measurable ore reserves aggregating 77,314,000 tons of an average assay of 2.17% copper. Ray Central had blocked out in 100-ft. sections, 6,711,000 tons running 2.19% copper and a 'high-grade' orebody dissected by 50-ft. drifts and cross-cuts of 673,000 tons at 5.83%. The Ray Central tonnage was determined from the assay-plans and vertical sections along north-south and east-west co-ordinates at intervals of 100 ft. Upon each of these the limits of the orebody were sketched, having in mind the system of mining to

be adopted and the accepted assay-limit of value. For convenience the property was divided into block-units of 200 feet. The prismoidal formula was used, separate computations being made for north-south and east-west co-ordinates and the average accepted. The geometric assay-average was calculated, all assays being weighted according to the number of blocks in which they were used. The total tonnage given was the total of individual blocks and the general assay-value was computed, using factors for block-averages according to tonnage. This method of estimating was fully described in the *Engineering and Mining Journal*, December 16, 1911. Equally satisfactory methods were employed by the Ray Consolidated engineers.

The ore reserves of Ray Central were confined to two isolated fractional claims of 29.93 acres, forming a wedge between the old Ray Consolidated and former Gila holdings. The ore-horizon is continuous through each property. The main levels of Ray Consolidated and Ray Central were driven at the same elevation; the ore was developed in each case to the common property-lines. Geographically, geologically, and economically the two properties belonged to one company. The advisability of consolidation was obvious to all.

In mining separately there was the danger of trespass beyond boundaries and damage to property. Mr. Louis S. Cates, representing the Ray Consolidated in the negotiations, estimated that 35% of the Ray Central low-grade ore would have to be left to support the lateral boundaries on a 60° caving line. He also figured that Ray Consolidated would forfeit nearly two million tons if the companies operated independently.

To recognize the surface claim-lines as the limits of mining possibilities would have been more serious to Ray Central, because the greatest thickness of proved ore was at the common south boundary. Even though a decision at court were granted to either claimant for trespass, the difficulty of appraising damage and attendant ill-will would mitigate against the success of operations.

The question of proportionate drainage-cost had to be considered and still more important was the threatened damage to the Ray & Gila Valley railroad, which crossed the Ray Central claims above the high-grade orebody. Owing to the topography of the land, no other practical route offered to connect the divided Ray Consolidated orebodies. Development of water and power, transportation of supplies and products, all these were vital factors. The Ray Consolidated was a producing mine, fully equipped to handle large tonnage; the Ray Central was thoroughly explored, its possibilities well defined, but it lacked adequate mine and mill equipment. I figured that to make Ray Central a steady producer (1500 tons daily) would cost $1,400,000 and consume 18 months. The banking phase of the situation was discussed by the directors and the relative advantages and drawbacks of unified or independent operation thoroughly thrashed out.

It was finally decided to appraise the properties on the relative net valuation of tonnage developed, setting aside the fact that $9,000,000 had already been expended by Ray Consolidated in the acquisition of property and the development and equipment of same; that the added tonnage of Ray Central would proportionately displace ore from the larger mine—which meant deferred realization of assets. The records of each company were open and the respective engineers acted in pleasant co-operation. Tonnages were checked, assays confirmed, costs studied, interest and amortization figured, and in the end there was practically a complete transfer of Ray Central stock on the basis determined.

	Ray Central.		
	High-grade.	Low-grade.	Ray Consolidated.
Tons of ore	673,000	6,711,000	77,314,000
Assay, percentage of copper.	5.83	2.19	2.17
Mine recovery, per cent	95	90	90
Tons recoverable	639,350	6,039,900	69,582,600
Net recovery at mill, per cent	85	70	70
Copper per ton of ore milled, in pounds	99.1	30.66	30.38
Concentration ratio	8 to 1	18 to 1	18 to 1
Copper per ton of concentrate, in pounds	793	552	547
Net recovery at smelter, per cent	95	95	95
Smelter yield per ton of concentrate, in pounds	753	524.4	519.6
Smelter yield per ton of ore, in pounds	94.1	29.1	28.9
Refining and marketing, at 2c. per unit, per ton of concentrate	$15.06	$10.49	$10.39
Smelting cost per ton of concentrate	6.00	6.00	6.00
Total smelting cost per ton of concentrate	21.06	16.49	16.39
Total smelting cost per ton of ore	2.63	0.916	0.91
Estimated mining cost	1.50	0.75	0.75
Estimated milling cost	0.55	0.50	0.50
Transportation, mine to mill, per ton	0.18	0.18	0.18
General expense	0.05	0.05	0.05
Total cost per ton of ore	4.91	2.396	2.39
Cost per lb. copper	5.218	8.234	8.27
Profit per lb. (copper at 14c.)	8.782	5.766	5.73
Total lb. copper recoverable.	60,163,000	175,761,000	201,094,000
Total profit	$5,283,500	$10,134,000	$115,226,800
Daily output of ore, tons	400-500	1,000	10,000
Life of mine, years	4	17	20
Annual profit	$1,320,875	$596,100	$5,761,350
Hoover's factor, at 7%	3.27	8.91	9.65
Present value of contained copper	$4,319,300	$5,311,250	$55,597,000
No. of shares outstanding	1,900,000	.....	1,350,000
Intrinsic value per share	$2.27	$2.80	$41.18
Total value per share	$5.07		

Relative value of stock, 8.1 shares Ray Central to 1 share Ray Consolidated.

The high-grade orebody of Ray Central was an inducement. From 400 to 500 tons per day was quickly available and Mr. H. Kenyon Burch, the consulting mechanical engineer, had estimated an extraction of 85% of its contained value. The production of copper from this source would make a favorable showing when some

stimulus was needed to the market. It was a quick live asset at a time when the grade of the average ore of the district was low, owing to the caving of surface stopes and consequent dilution due to admixture of capping and oxidized material.

Representing Ray Central, I used the following method in determining the proper ratio of exchange. (See tabulation). At a stockholders meeting, in June 1912, the Ray Central ratified the action on a basis of eight shares of Ray Central for one share of Ray Consolidated.

The term 'Hoover's factor' is taken from Mr. H. C. Hoover's 'Principles of Mining,' Table I, page 46. The present value of contained copper represents the amount that will be repaid out of the profit assured, together with 7% interest, when the annual payments into sinking fund earn 4 per cent.

This transaction took place in 1912. It is interesting to compare the estimates with actual figures as given in the sixth annual report of the Ray Consolidated Copper Co. just issued. The production for 1914 was 59,044,700 pounds of copper from high-grade crude ore and concentrate. The smelter recovered 57,004,281 lb., or 96.6%. The average net price received for copper was 13.26 cents. A re-calculation of tonnage, based on more recent underground developments, gives 74,765,789 tons averaging 2.14%, but from former estimated tonnage, 7,061,821 tons at 1.74% has been mined. It must be remembered that this ore comes from the top and irregular fringes of the proved orebody, so that it is partly oxidized and diluted with capping. It does not represent the true run-of-mine. This explains the apparent discrepancy in grade between that estimated and actually mined to date.

Owing to the fact that the mine is now in good working order, the daily output is maintained largely from the reserve drawing of stopes, thereby considerably lessening the mining cost of former years. The total mining cost for the year was 62.42 cents.

Selective stoping of the high-grade orebody was adopted, so that comparison with my estimated cost is not possible. Sorted ore to the amount of 2591 tons averaging 11.86% was shipped direct to the smelter, the remainder going to the mill. Square-setting and waste-filling bring the cost up to nearly four times the average of all the ore mined.

A daily average of 6651 tons of ore, assaying 1.76% copper, was milled throughout the year, but the output was curtailed to one-half normal from August to December. The average recovery was 67.88%, or 23.9 lb. per ton. This would have been better but for the remodeling of the mill during the period of curtailment. The cost of milling was 49.88 cents. The average grade of concentrate was 19.25% copper, a concentration ratio of 16 into one.

The cost of production was 8.839c. per pound, which includes all operating and general expense as well as 12½c. per ton of ore milled applied to the retirement of mine-development cost. Crediting all miscellaneous income, the net cost per pound was 8.763 cents. These figures show a net profit of 4.497c. per pound copper produced, or $2,563,480 for the year.

San Francisco, October 2. FRANK H. PROBERT.

Why Is Flotation?

The Editor:

Sir—Mr. Durell's article on this subject in your issue of September 18 is interesting. I believe that an exchange of ideas on this subject is very desirable, and it may be that some of the information that I have collected may be of interest to the readers of the PRESS.

The arguments which Mr. Durell's article presents are, briefly, that floatable particles cannot attach themselves to previously formed bubbles, but must be floated by bubbles which form themselves on the surface of the particles so that there is no surface film of water between the particle and the air. To explain the formation of these, Mr. Durell assumes that the water is super-saturated with dissolved air and that there is a certain amount of "occluded" air on and in the surface of the particle, and that these combine to form bubbles. That this occluded air may be present is certainly possible, but that it would be liberated with sufficient rapidity to float the particles does not seem probable. That the water in a M. S. type of machine is super-saturated with air is also probable, but I cannot see how the water in a Callow or other pneumatic machine can become greatly super-saturated by the introduction of air through a coarsely porous medium such as canvas twill.

The idea of super-saturating the water with air is not new. As early as 1907 D. H. Norris patented this process. (U. S. patents No. 864,856 and 873,586.) Mr. Norris saturated water with air at a pressure of several atmospheres, and introduced it into an open tank at normal pressure, where the excess air formed what he called "infinitely small nascent bubbles of gas" which were supposed to float the sulphide particles. So far as I know, this idea has never been put into successful operation.

As to Mr. Durell's statement that the dissolved and occluded air are indispensable; if it is true, previous boiling of the pulp, which would drive out all of the dissolved and some of the occluded air, should interfere considerably with flotation, especially in a pneumatic machine. I have seen this done in the laboratory of the General Engineering Company. The subsequent flotation took place with practically the same rapidity and cleanliness as when the same ore was floated without boiling of the pulp. Furthermore it has been my observation, that when a carbonate ore is treated with soluble sulphides for the purpose of forming an artificial film of sulphide on the surface of the mineral particles, much better results are obtained when a small amount of alkali is added to the pulp to remove any traces of H_2S gas. This can also be accomplished by the use of SO_2, which reacts with the H_2S to form sulphur and H_2O, and does not leave an alkaline pulp. Were Mr. Durell's hypothesis true, this gas should be beneficial rather than detri-

mental, and it would seem that the general effect of artificial sulphiding would be to reduce the amount of occluded air rather than increase it, as some of it would undoubtedly be displaced by H_2S which would later be removed.

I cannot agree with Mr. Durell's statement that floatable particles will not attach themselves to previously formed air bubbles. I understand that in the suit of the Minerals Separation, Ltd., *v.* Miami Copper Co., heard at Wilmington last May, the plaintiff presented to the Court a moving picture of an experiment in which it was shown under just what conditions the particle would attach itself to the bubble. Aside from that, it is not a far-fetched assumption that the air bubbles in an oil-emulsion have mantles of oil. Their property of frothing would so indicate, and, in that case, the surface films of water surrounding them would not differ materially from the films surrounding drops of oil suspended in water. That such drops of oil can collect floatable particles out of an ore can easily be proved by shaking oil with a mixture of galena and sand suspended in water. When the oil has collected, the drops will be seen to be covered with the galena. If we imagine the centres of these drops to be filled with air instead of oil, we have conditions which might easily hold in an actual flotation machine.

On the whole, Mr. Durell's hypothesis does not seem to conform with actual flotation practice. There are other theories that explain flotation in better conformity with known scientific facts. T. J. Hoover, for instance, in his book 'Concentrating Ores by Flotation,' presents a consistent theory, and J. M. Callow presented a paper to the Utah Section of the American Institute of Mining Engineers in which were set out some theories based on experimental work done at the Mellen Institute and at the local station of the U. S. Bureau of Mines. This paper will undoubtedly be published soon in the transactions of the Institute.

Salt Lake City, October 6.

Office Etiquette for Busy Men

The Editor:

Sir—The protest by Mr. Worden in the PRESS of October 23 on this subject should appeal to a wide circle of readers. Relative to the discourtesies inflicted on their business callers by pompous officials, a friend of mine (a chief engineer for a large mining company) used to remark that the more petty the official the more disagreeable he was liable to make himself, while the man of real authority is apt to be a considerate and gracious personality. I think it is often the case that a pretentious little office-man, holding a 10-cent job for a ramified corporation, loves to exhibit his fussiness and suspicion, but that a really big man, who does things worth mentioning, may seem even too much inclined to trust everybody. I sincerely believe, however, that courtesy in business is spreading rapidly. When the big corporations were first promoted the habit of curt unpleasantness obtained, in a belief, apparently, that all great men are gruff and impolite. Nowadays, the visitor at an important New York office (formerly the much-heralded abode of 'get-there' abruptness) is likely to be astonished at the quiet civility and considerate discernment. Occasional anachronisms remain, of course, and a caller sometimes finds himself cooling his heels under the suspicious surveillance of a commissionaire, but such cases are mostly, as my friend said, the pitiful attempt of a petty nobody to assume an air of consequence.

Berkeley, October 26. P. B. M.

Mining School for Employees

The Cleveland-Cliffs Iron Company, which operates about a dozen iron mines in Michigan, has maintained a mining school for its employees for three years. The purpose of the school is to teach mining to a selected number of employees, picked on the basis of their ability by the superintendents and foremen. Very few of such Industrial Corporation Schools exist in the United States but there is a great number of them in Germany, where they are credited with having been largely instrumental in producing the remarkable industrial development of that country during the past 20 years. The instruction is by lectures, classes, and mimeographed or printed instruction-sheets. At first the employees did not take well to the idea, although a few welcomed it, especially those who had already attempted to help themselves through correspondence-schools. Gradually prejudice was broken down, especially after the company authorized the statement that, so far as possible, all new shift-bosses would be chosen from those attending the Mining School. At the first class there was an enrolment of 38 men, of whom 33 completed the course successfully. It is interesting to note that two shift-bosses have been picked from the men who attended the school. The work of a class is planned to cover 18 months; there are two classes per week, each of $1\frac{1}{2}$ hours, one of which is in the afternoon for men working on night-shift and the other is in the evening for men working day-shift. All class-work is done on the miners' own time; they receive no remuneration from the company for the time given. Personal friendship with the men and a capacity for patience are cultivated by the instructor, these being largely contributory to the success of such a school. Only English-speaking men are taken; of the first class, 13 were American-born, 12 were English-born, 4 Finnish-born, 2 Swedish-born, and 2 Italian-born. The following subjects and phases of mining are taught: arithmetic, drawing, geology, use of mine-maps and blue-prints, first-aid, time-keeping, ore-sampling, stoping-methods, business-correspondence, use of a compass, elevations, etc. To educate mechanics and electricians, the engineers in the mechanical and electrical departments of the company conduct separate evening classes, one per week; any employee engaged in these branches of work is privileged to attend.

Planning Mine-Equipment

By P. B. McDONALD

Since buying of mine-equipment is being discussed, it may be worth while to touch on some modern developments in that line. Coincident with the tendency toward concentration of plant and the working of low-grade ore-deposits in a big way has come the practice of having expensive fire-proof buildings, increasing repair-shop facilities, modernizing the boiler-plant, and improving equipment in such hitherto neglected details as oil-houses, concrete-foundations, and sanitation. The growing belief in well-constructed and labor-saving equipment, with attention paid to workmen's comfort, ventilation, light, safety, fire-proofing, and automatic devices, has tended to elaborate initial installation over a proved orebody, and to augment considerably all first-cost construction. Far-sighted companies have even preferred to build a permanent steel or concrete structure where the cost works out about the same as a series of equally serviceable wooden installations. They deem it more business-like and satisfactory. Thus the Cleveland-Cliffs Iron Co. put up a mammoth and costly steel stockpile-trestle at its big Negaunee mine, rather than build and tear down a timber trestle at each shipping-season, though the final cost for the estimated life of the mine figured out about the same in either case.

The tendency at large mines is to construct mine-buildings of brick or concrete, and steel. Roofs may be of a variety of materials, concrete, special cement-plasters on light steel re-inforeings of chicken-wire or perforated metal, metal-sheetings, paper, tile, slate, and patent materials of various kinds. Steam-plants of several boilers are arranged to draw into one common stack, which may be of concrete, brick, or steel, and may be self-supporting or guyed. Light steel head-frames of two-post or four-post varieties, put up with fastenings in the joints like spring-cotters instead of rivets, so that the head-frame can be taken down and erected elsewhere, have become comparatively reasonable in price and more or less standardized in design. Steel and concrete oil-houses make a surprising saving in oil, being arranged with permanent steel barrels under the floor and equipped with pumps for filling cans. Concrete foundations under crushers, engines, head-frames, stacks, and 'location' dwellings are popular.

On account of the variety of special processes for mine-construction, a mining company in asking for bids on a building and accessories has a considerable range of choice. There is also an opportunity for the mine-engineer to do a lot of planning, estimating, and revising in drawing up specifications on which the constructing companies may bid.

For instance, some mining companies on the Michigan iron ranges have built machine-, carpenter-, and blacksmith-shops not in three buildings as formerly, but in one long building, separated by partitions to keep smoke or dust from circulating. This plan was adopted to save construction costs; it makes for convenience in taking work from one shop to another, especially in winter, a narrow-gauge track for a push-car running through the shops. Many different ways can be devised for housing the same machinery and equipment, each with its advantages and disadvantages in convenience, space, windows, cost, and lay-out. Changing the shape of a building, spacing trusses and purlines differently or altering the style and angle of the roof, may give the same results at appreciable reductions in price. An engineer with a bent for analyzing different estimates, and with plenty of time for his computations, can save a company not only a large amount of money in first cost, but by anticipating operating economies and conveniences can accomplish enduring results in routine. It is pertinent to remark that permanent construction is difficult to alter after once completed; particularly is concrete a stubborn substance to drill, cut, or break.

One mining company in Michigan that planned an elaborate system of electrification of its pumping, hoisting, and air-compressing, at a dozen mines scattered over rather a wide territory, sent several members of its staff to Europe to inspect installations of the most modern and approved types. The results attained were most satisfactory. By damming a comparatively small stream (partly composed of mine-water pumped from its mines) and conveying the water several miles in wooden and steel pipe, a head of some hundreds of feet was obtained; the turbines, control, and equipment are of particularly elaborate order. In much the same way the Dome Mines Co., of Porcupine, previous to the building of its mill and development of its mine, sent two of its officials to inspect gold mines in the West and Alaska.

Several mines on the Michigan iron ranges have concrete-lined tunnels just below the surface of the ground from shops and change-house to the shaft. Thus, drill-steel, rock-drills, pumps, etc., can be brought from underground to the shops without inconveniencing operations around the top of the shaft. And the miners can pass to and from the change-house to the man-cage without going outdoors; this is especially convenient in winter, when at other mines crowds of miners in wet clothes have to wade in snow or wait for the cage in a storm. A narrow-gauge track with push-car supplements the tunnel to the shops.

A special building-material for walls, roofs, or floors, called 'Hy-rib,' made in Detroit, has proved popular on the iron ranges; it is a cement-plaster on a light, perforated, and roughened metal re-enforcing. Curved

roofs for a mine oil-house can be made handily with it, the re-enforcing first being fastened to the steel members of the walls. Sometimes, as for a change-house roof of rather flat design, concrete over a re-enforcing of old rails is used. For a roof sheltering machinery, such as hoists, compressors, or dynamos, some engineers claim that concrete roofs 'sweat' and drip water, tending to rust the machinery. The matter of a roof is more important than at first appears. Owing to the steel trusses and purlines, and to the increased area on account of arching, roofs are costly; therefore any way of saving roof-space is worth considering. Windows are also important details, and well repay careful planning. In climates where snow does not complicate roof-loads, roofs can be flatter, although in a windy district snow blows away practically as soon as it falls on a roof.

Electricity is playing an increased part in mine-operating. In the submarine iron mine of the Nova Scotia Steel & Coal Co., on Bell island, Newfoundland, electric underground 'steam-shovels' of an over-all height of 12 ft. above the rail and the ability to turn completely around in a radius of 25 ft., have given excellent satisfaction in the stopes. Electric hoists are, of course, now quite common; some of the cheaper, simpler ones suitable for small mines operate apparently much like a trolley-car. Hoists with the expensive motor-generator set, with fly-wheel that will run for hours after the electricity is shut off, will operate on a surprisingly small constant current with a flat load-curve. Electrically-driven air-compressors, both belted and direct-connected, are a proved success. The direct-connected Ingersoll-Rand compressor, with 'clearance-control' device for regulating current to meet the varying needs of air in the line, have been installed at a number of iron mines in Michigan. Electric plunger-pumps seem to be preferred in efficiency over the centrifugal style in large wet mines, but the multi-stage centrifugal pump with several relays for deep mines is a much-liked feature on account of its lower price, compactness, simplicity, and ability for handling muddy water.

The popularity of the Prescott steam pump for the very wet mines of the Mesabi range is conceded; they have the name of being economical on steam. For explorations, rough-and-ready work, pumping mud, sludge, or dirty water, the old reliable Cameron tappet-valve pumps in their various sizes, persist in spite of their extravagant use of steam; nearly every iron mine in Minnesota and Michigan keeps Cameron-pump valves, packing, and springs on hand, and has several Camerons around the job somewhere. Incidentally there is a particularly powerful centrifugal pump of Cameron manufacture now on the market.

Herring-bone gears (of the Wuest type) have attained some success for geared hoists at the bigger Lake Superior iron mines, being noiseless and easy-running to an unusual degree. I remember seeing an 'expert' come from the factory to re-adjust a set of herring-bone gears at a new plant. He made a measurement and then ordered the gears moved a certain small fraction of an inch closer together, after which they ran perfectly.

Geology of Tintic

*This district is in Utah, 65 miles due south of Salt Lake City. It has produced silver, lead, gold, and copper amounting to $143,398,119, up to January 1, 1914.

There are three types of ore deposits in the district:

1. The limestone-igneous contact deposits that are widely distributed, particularly northward, but these have no economic importance.

2. Deposits in igneous rocks. The ore deposits in the igneous rocks are confined to the southern half of the district, where they occur as veins, varying in width from a few inches to 10 ft., usually pinching with depth. The average width is about 2 ft. The ore in its unaltered state consists of silver-lead sulphide and sulph-arsenides, occurring in bands and lenses in a gangue of quartz and pyrite. Since the closing of the Swansea mines there has been no noteworthy production from deposits of this type.

3. Replacements in limestone. The orebodies of this type are confined to the northern half of the Tintic district, and include all the mines now productive. Like replacement deposits in general, those of Tintic are very irregular in form; if any one form of orebody can be said to be typical, it is that of an irregular sheet, pinching and swelling along the line of the beds, and feathering upward into chimneys or pipes. Where the ore-channel is crossed by faults or zones of fracture, there is usually an enlargement of the orebody along the line of intersection of the faulting and the bedding.

At the intersection of the ore-channel by a fault, it is not an uncommon occurrence to find that the line of mineralization turns from the plane to the beds and follows the fault for distances up to 100 ft. or more, before again taking the usual course along the beds. Occurrences of this kind probably also account for the occasional division of a single ore-channel into two or more in parallel. Other things being equal, the coarser-grained, softer, and less silicious limestone are more susceptible to mineralization than are the fine-grained more silicious and harder ones, while the associated shale, sandstone, slate, and quartzite are uniformly barren.

By reason of the folded and broken state of the limestone beds, the ground-water level is extremely low (about 4765 ft. above sea-level), in the sedimentary rocks. This puts it at depths beneath the surface of from 2300 ft. in the higher properties to 1500 ft. in those having shafts at relatively lower positions. This condition has led to nearly complete oxidation of the original sulphide ores, with some downward segregation of the ore-minerals, and some enrichment due to shrinkage in volume.

The occurrence of ore within the monzonite and in the limestone; the character of the mineralization, the progressive change in the mineral composition of the ore with increased distance from the monzonite—all point to this rock as the factor in the mineralization.

*Excerpt from a paper by Guy W. Crane to be presented at the New York meeting of the American Institute of Mining Engineers, February 1916.

The Determination of Mercury in Cyanide Solution and Precipitate

By W. J. SHARWOOD

The most direct and reliable methods for determining mercury in ores depend on the distillation of the metal from the dried material under examination, reducing it to the metallic state if necessary by means of quicklime or metallic iron; the condensed metal is best collected by means of a weighed piece of gold or silver foil.

Several convenient arrangements of apparatus have been devised for the direct assay of low-grade ores. One of the best of these was described by W. W. Whitton,[1] in which a flanged crucible or wide-mouthed retort, turned from a piece of mild steel, is used with a light cover of silver foil, cooled by a flat-bottomed brass dish of water, the whole system being connected by a clamp engaging a steel plate with a hole in which the crucible fits. The earlier method of Eschka[2] uses a porcelain crucible with a gold cover, hollowed to contain water for condensing mercury; similarly Chism[3] employs a porous annealing-cup covered by a flat piece of silver foil on which rests a metal dish of water. G. A. James[4] has described a somewhat more elaborate arrangement in which the silver lid of a nickel crucible is cooled by a copper box through which water circulates.

Similarly one can use a thin-spun iron crucible, best one of the type provided with a rim; or the hat-shaped nickel crucibles sold for determining carbon in steel. The crucible should be fitted into a hole in a steel plate, or in a sheet of 'transite' asbestos wood (not ordinary soft sheet-asbestos) which is stiff enough to allow of clamping the cover on, if necessary. A small flat 'tin' box, with the tin carefully sandpapered off the bottom, will answer for the cooling system.

In any case the material is mixed with clean iron-filing, or well-burned quicklime, or preferably with a mixture of both, covered with the same material, and heated for 15 to 20 minutes, the bottom of the crucible being maintained at a dull-red heat, while the gold or silver cover is kept cool by water, which may be allowed to boil throughout the assay, and must be replaced from time to time as it evaporates. It is then allowed to cool about two minutes, the foil is quickly removed, rinsed and dried if necessary, left a few minutes in a desiccator, and weighed. The difference between the original and final weights, to the nearest tenth-milligram, is due to mercury condensed. On heating nearly to redness for a minute the foil returns almost to its original weight.

Gold is preferable to silver for catching mercury, because a mere trace is visible on its surface and it absorbs a larger amount on a given area. A silver disk 2 inches in diameter will hold about 50 mg. of mercury without difficulty, and even 100 mg., and may weigh 2 to 4 grams. The iron filing should be fairly fine, preferably passing 50 or 60 mesh, but having the dust removed by sifting over a 100-mesh sieve. The material known as 'crushed steel emery' (50 mesh) is better than filing. In any case, grease should be removed by treating first with alcohol, then with ether or benzene, and drying thoroughly.

The amount of ore should, if possible, be adjusted to give from 20 to 50 mg. of mercury; usually between 0.5 and 5 gram may be taken. If it contains organic matter (asphaltum, etc.) or much free sulphur this should be removed by carbon disulphide or benzene, and the ore should be quite dry when put into the apparatus. Usually about 5 grams of iron or lime is sufficient to mix with the ore, and half as much to be used as a cover.

When a Bunsen or Meker gas-burner is not available, a large alcohol-lamp may be used, but a Dangler gasoline-burner is much better and is fully as satisfactory as gas. The same apparatus is available for the final collection of mercury from cyanide precipitate and solution.

In Cyanide Solutions. When found in working solutions the mercury is usually in very small proportions, expressible as a few parts per million and comparable in quantity with the gold present. In exceptional cases, as when treating old pan-tailing, or when concentrate is ground with mercury and strong cyanide solution, as at Cobalt, much larger amounts may be dissolved. The metal itself is slowly soluble, but mercuric oxide is readily dissolved by cyanide solution; mercurous salts are decomposed, half of the mercury dissolving and half being separated as metal. In the resulting solution it exists as double sodium or potassium mercuric cyanide ($Na_2Hg''Cy_4$ or $K_2Hg''Cy_4$). This does not respond to most of the ordinary tests for mercury, but is decomposed by soluble sulphides and by metallic zinc or aluminum. In precipitating gold and silver by the usual methods, therefore, nearly all the mercury is thrown down with the precious metals.

In ordinary cases, where the ordinary tests fail to precipitate mercury, its presence may be detected by precipitating a large sample of solution in the first place by metallic aluminum, or zinc-dust, as in the Dowsett test for gold, then acid-treating and examining the small

bulk of precipitate left. When using zinc, care must be taken to distinguish a sublimate of metallic zinc, cadmium, or lead compounds, from one due to mercury; aluminum is to be preferred as a precipitant. The following method has been found to yield most satisfactory results, qualitatively and quantitatively. One part per million can be readily detected and weighed, if 1000 cc. be taken as a sample.[5]

Measure 1000 cc. of solution into a 2500 cc. acid-bottle, give the contents a rotary motion and add half a gram of the finest aluminum powder. Shake the bottle violently for half a minute, then give it a rapid rotary motion and allow to stand for a half to one minute; by this means the solution continues moving most of the time. Repeat the violent shaking, etc., at least 6 times—a total of 5 to 10 minutes. Meanwhile prepare a porcelain Gooch crucible, covering the perforated bottom with a layer of fine asbestos, and connect with an empty 2500 cc. bottle attached to a good vacuum-pump. A brass Chapman or Richards filter-pump, giving a vacuum of about 20 inches, will usually handle several filtrations at once. Shake the solution again and pour it all through a large funnel into a 1000 cc. narrow-necked flask. Rinse the bottle twice with a little water and catch the washings in a small beaker. Pour the washings into the flask until nearly full, and pour the remainder upon the Gooch filter. Invert the flask over the filter with the mouth at least half an inch below the rim, clamp it in that position, and then allow the liquid to filter, using a good vacuum. It may require two or three hours to pass through. Remove the empty flask, rinse any adhering particles into a beaker, and transfer to the filter. Wash once with distilled water. When sucked dry, wash once with alcohol, using a pipette to rinse down the sides of the crucible; when drained, wash twice with a little ether to remove any oil, etc. Remove the crucible and heat gently till thoroughly dry; transfer the asbestos filter-pad and contents to a Whitton or similar mercury apparatus with a weighed gold foil, and proceed exactly as with ores.

Using 1000 cc. of solution, every milligram found corresponds to one part per million, and half a milligram of mercury is easily visible on gold foil. If the solution is very low in alkali and in cyanide a gram of caustic soda may be added; much more is undesirable. In case of doubt there is no harm done by using additional aluminum powder.

Zinc-dust is not a satisfactory substitute for aluminum; the excess of zinc must be removed by hydrochloric acid, and the cadmium it contains also interferes.

In Cyanide Precipitate. The precipitate, obtained by treatment of cyanide solution with zinc-dust or shaving, may contain mercury in the metallic state or as sulphide. The latter appears to be produced largely by the action of nascent hydrogen upon thiocyanates in the solution, during the reaction of the zinc with alkaline hydroxide, etc., in presence of mercury compounds, the thiocyanate being formed by the action of cyanide upon thiosulphate (CaS_2O_3 etc.), which in turn results from the action of hydroxides upon sulphides in the ore treated. Alkaline sulphides as a rule occur only transitorily in well-regulated cyanide solutions. The mercury in cyanide solutions is obtained from oxidized or finely divided mercury in the ore or tailing, the metal being slowly attacked and the oxide readily soluble. Metallic mercury in precipitate probably exists mainly as amalgam, in combination with gold or silver, or with unaltered metallic zinc. Sulphuric acid refining leaves both mercuric sulphide and the metal in the residue.

The best rapid qualitative test for mercury is to thoroughly dry a portion of precipitate and heat in a hard-glass tube, closed at one end, to strong redness. It is rendered more delicate by first extracting metallic zinc with warm dilute hydrochloric acid, washing thoroughly and drying; and by mixing with clean iron-filing and well-burned quicklime to decompose sulphide. The presence of gold and silver makes it more difficult to volatilize the mercury and necessitates heating more strongly. When distinct globules are not recognizable in the tube a small piece of gold foil, wrapped round a wire, should be rubbed inside the tube and examined. Care must be taken to distinguish between a sublimate of metallic mercury (forming distinct silvery globules) and one of cadmium, which is sometimes obtained from precipitate, and which comes from certain zinc-dusts, both domestic and foreign, from cadmiferous zinc ores. Cadmium in zinc-dust tends to concentrate in the resulting precipitate, and still further when the precipitate is acid-treated in the refining process.

In using the Whitton or similar apparatus for collecting mercury upon silver foil, the quantity of material taken for analysis should not contain over 0.10 gm. of mercury, and preferably 0.025 to 0.050 gm. From 1 to 2 gm. of precipitate is usually a safe amount, but some slime and concentrate precipitates have yielded over 10% mercury when raw, and considerably more after acid refining.

Place the weighed sample in a 150 cc. beaker with watch-glass cover, moisten, and add 10 or 15 cc. dilute hydrochloric acid. When action slackens add more acid, and finally heat gently until action ceases. All the lime, practically all the zinc and cadmium, and some copper and lead pass into solution. Dilute with warm water, stir, and allow to settle, and pass the clear liquid through an asbestos Gooch filter, using gentle suction. Heat the residue with a little more acid, dilute and filter as before; finally transfer all the residue to the filter and wash with hot water till all chlorides are removed. The filtrate may be used for the determination of calcium and zinc, and for cadmium if the residue has been thoroughly extracted with acid.

The residue contains all the mercury. As soon as it is sucked dry, wash once with about 10 cc. of alcohol (denatured may be used), using a pipette to rinse the sides of the Gooch crucible; then wash at least twice with

[5] A solution of mercuric chloride, as dilute as this, gives no appreciable color with hydrogen sulphide; with five parts per million a distinct brown coloration is obtained.

ether to remove grease, asphaltum, etc. These washings are discarded unless the organic matter extracted is to be determined by evaporation in a watch-glass. Disconnect the Gooch crucible and dry it in an oven or on a hot plate, avoiding a high temperature. Transfer the asbestos mat and residue to a suitable apparatus (Whitton or Eschka) with a weighed disk of silver or gold foil. Wipe out the Gooch with a wisp of dry asbestos and add to the residue in the retort. Add 5 gm. clean iron-filing or crushed steel and a little well-burned quicklime, and grind up with the residue, using a stout glass rod. Cover with 2 or 3 gm. of iron or lime. Clamp foil and cooler upon retort, heat for about 20 minutes, etc., exactly as with ores, and weigh the foil with condensed mercury.

Trade Openings in China

Gold is found in many parts of the province of Szechuan, China, but not always in paying quantities. According to a recent report from Chungking, the most important mine in Szechuan that has thus far been opened is located at a very mountainous place called Maha, which lies in the south-western corner of this province about fifty miles north-west of Ningyuanfu. The Government is very anxious to develop the Maha mine to the fullest possible extent, and is now undertaking a thorough reorganization. Two Chinese engineers, who studied mining engineering in Belgium, are employing a corps of trained assistants and about 1200 miners in the mining work at Maha. Both the Government at Pekin and the provincial authorities are giving them every encouragement, and there is reason to believe that this project will finally succeed. New mining machinery is needed to carry on this work to the best advantage. This opportunity is exceptional, inasmuch as the installation of a plant at Maha would doubtless result in further developments, since not only gold is found in the western part of this province, but antimony, iron, lead, silver, and copper also occur in considerable quantities, and will be mined eventually by up-to-date methods.

The great drawback to trade in the province of Mengtsu has been the lack of representatives to push the sale of their goods. The present time is exceptionally favorable for such an enterprise, as the two German firms which have hitherto supplied local buyers with machinery, etc., can now obtain no further supplies. There are inquiries for irrigation pumps, electric light machinery, flour and rice mills, material for the installation of waterworks in Yunnan-fu, locomotives and trucks for the Pishihehai Railway, and other items; but these can only be dealt with by a man on the spot who is prepared to make a contract for the goods delivered c.i.f. at Haiphong, possibly assist to some extent in their erection, and arrange the question of exchange.

According to a recent official report, the district of Tzeliuching, which lies in the south-central part of Szechuan, some fifty miles north of Suifu, is the most important industrial centre in West China. This is true not only as regards its present state of development, but also as regards its potentialities and possibilities. Tzeliuching at no distant date will place larger orders for foreign machinery than any other city in this part of China. Machines for drilling new wells, for pumping up the brine, and for evaporating the salt are of first importance. Simple hoisting engines to supplant the water-buffaloes should enjoy a large sale. Gas-stoves and burners and engines using gas for fuel could also be introduced. As the salt-wells are operated night and day, there is an excellent opportunity for the sale of electric-lighting plants. Telephone-apparatus is also in demand, and mine pumps and machinery are needed in the coal-fields.

Writing on the resources of the Kaihsien district, the American Consul at Chungking, Szechuan province, says that while there is not much chance of introducing textile-machinery at the present time, if factories are started and the industry develops to any extent, there ought to be a market for cheap looms of simple construction. Mining machinery might even now be sold to advantage, both for coal and iron, and a modern smelter might be established very profitably at Ma-chia-kou or Wen-tang-ching. With the cheap labor and the extensive deposits of iron and coal, there is no reason why the Kaihsien district should not become in the course of time an important manufacturing and industrial centre.

He also points out that, as the district about Chengtu develops, there will be an increasing demand for foreign machinery. Mining machinery is needed in the development of the region west of Kwanhsien, where lead, coal, silver, and copper deposits are said to be extensive. There is also a demand for machinery for the scientific refining of salt and sugar, and for the manufacture of paper, shoes, soap, candles, and many other articles. Modern sawmill machinery will eventually be introduced. Machinery for silk and cotton weaving could be used to advantage; much of the Thibetan wool that comes from Tachienlu to Chengtu could be made into fabrics at the latter city, where labor is cheap and water-power available.—*Journal of the Royal Society of Arts.*

Malachite is used in America for cuff-buttons, scarf-pins, and other articles of jewelry. When a Russian visitor was shown a chain of malachite by its proud possessor he remarked: "We build houses of it in my country." This statement was an exaggeration, but malachite is actually used in Russia for tables, mantle-pieces, and for columns in churches. These furnishings are, of course, not of solid malachite but veneered. In the Mining Institute, at Petrograd, there is a block of the pure mineral weighing 3400 lb. and valued at $15,000. The largest mass yet reported was found in the Myednorydyansk mine in the Urals, in 1835, at a depth of 240 ft.; it weighed 328 tons.

The mints of the United States coined 7,825,250 pieces during September, valued at $2,462,880; also 600,000 pieces for the Philippines, and 1,780,000 for Cuba. This use of silver is beneficial to mining.

Mining in Utah

By L. O. HOWARD

Development proceeds steadily in the Cottonwood districts. In addition to the Cardiff, South Hecla, and Michigan-Utah mines, the Sells and the Maxfield apparently have good bodies of ore. An impetus has been given to leasing by the results obtained at the Michigan-Utah, and discoveries, that should lead to further shipments of ore, have been made by lessees on other properties. The month has been marked by the payment of the first dividend in several years by one of the Cottonwood mines. The Cardiff company distributed $125,000 on October 1, this being at the rate of 25 cents per share on a stock that less than a year ago was sold for one-quarter of this dividend. The amount of ore being developed and the favorable indications for the finding of more have caused different interests to investigate the transportation problem in Little Cottonwood canyon. One project involves a narrow-gauge cog-wheel railway connecting the mines at Alta with the railroad terminal at Wasatch. This enterprise is in the promotion stage only, but if brought to a successful issue it will undoubtedly facilitate the shipment of lower-grade ore. There has been some talk of a new aerial tramway, but as yet little progress has been made toward a realization. It embraces two alternate arrangements, either an 8½-mile tramway from Alta to Wasatch, or an extension of the railway to a point a short distance below Tanner's Flat, to connect there with an aerial tramway from Alta.

One difficulty with any system of transportation in the upper canyon is the ever-present danger from snow-slides in the early spring. The sides of the canyon are cut by numerous gulches, which are steep and generally free from vegetation. The tramway that is now in use has been disabled each spring. An attempt to overcome the difficulty was made by constructing concrete piers on which single steel columns were erected to carry the track-cables, the idea being to reduce the resistance to slides. These supports simply 'jack-knifed' and pulled down the line.

The PRESS has reported the fatal accident at the Albion adit, where one man lost his life through remaining in a gaseous atmosphere until the oxygen in his helmet was exhausted. An ingenious plan was devised to recover his body. Men armed with punches perforated the air-pipe at four-foot intervals and were able to proceed gradually to the face of the adit.

Inquiry for the rare or little-used metals has increased. Manganese, antimony, molybdenum, and tungsten are in most demand. Few of these inquiries have led to business, the chief reason being the widely divergent views of vendor and purchaser. Mines producing these metals have not been developed in the territory tributary to Salt Lake, simply because there was no market for them prior to the War; consequently prospects alone are available. The prospector demands a substantial sum for his property with an immediate payment down, his view of the situation being erroneous. On the other side the buyer is generally only willing to contract for the ore and objects to assuming any of the risk of the venture. Both are wrong. A middle course, involving the payment of money by the capitalist to develop the properties for the mutual benefit of both parties on a proper leasing basis would be a desirable solution. The market, as far as anyone can foresee, will collapse at the end of the War; therefore it is manifestly unfair to ask the prospector to assume all the risks of development. On the other hand, he is wrong in asking an exorbitant price for a prospect that may have only a temporary value.

A sure index to the condition of mining is the increasing number of orders for patent-survey that have been filed in the local office of the U. S. Surveyor-General. I have tabulated these on the basis of the number of lode-claims for which orders have been issued in 1913, in 1914, and the first nine months of 1915. It appears that in the nine months of this year the number of claims ordered surveyed for patent exceeds the sum of those in the two years preceding. Whereas in 1913 one-third of the claims were in districts that I have called 'miscellaneous,' where it is likely the ground had been held for years, being finally patented to avoid assessment work during uncertain times, the four active districts of Bingham, Park City, Beaver County, and Cottonwood account for about one-half the number in 1915, while the remaining one-half are mostly carnotite claims in Emery and San Juan counties. Each of the four districts has made a gain, that in the Cottonwood being of special interest.

The large number of carnotite claims in the list for this year will doubtless cause surprise, but the work has been completed at most of them. The desire to patent is based both on the necessity for being in a secure position in the face of any legislation that may be attempted with a view to withdrawal, and the impracticability of doing extensive assessment-work on claims where any quantity of shipping ore is exposed, because of the lack of a market. Carnotite claims are developed in a manner peculiar to this particular type of deposit. Nowhere is the slogan "Follow the ore" more imperative. Nearly 100% of the orebody is extracted by development. The most economical results are obtained by employing a force so organized that the inevitable dead-work will be in a sufficiently low proportion to the total development. Economy is imperative when, as in this case, the cost of the ore f.o.b. cars is at least $55 per ton. These factors have influenced owners of good claims to seek patents.

Usually Utah has risen to the occasion when development of new minerals was demanded. At the time when

the growth of Salt Lake City called for modern buildings, supplies of granite, marble, onyx, and travertine were developed immediately. When radium was sought, Utah responded with large areas of carnotite ore. When the War caused a crisis in the fertilizer industry, the first commercial exploitation of potash was undertaken in this State. All of the rare hydrocarbons, such as gilsonite, elaterite, and ozokerite, have been found and produced locally. Oil alone is unrepresented. Yet a reserve may be available in the widely distributed oil-shales of eastern Utah, to be developed in time. Excellent iron-ore deposits await the favorable combination of circumstances that will afford the basis for an iron and steel industry in this region. A list of the economic resources of the state should not omit gypsum, the source of the plaster used for most of the buildings of the Exposition at San Francisco [Nevada also supplied a large quantity of gypsum for the Exposition.—EDITOR.]; the salt beds of the Great Salt Lake; and the natural asphaltic paving material of the Wasatch and Uinta mountains. Coal from Utah has furnished the coke that has been a big factor in making Salt Lake Valley a great smelting centre.

To those interested in flotation, I may mention the paper read in abstract by Mr. J. M. Callow at the recent meeting of the Utah Section of the A. I. M. E. It was replete with details of the equipment and operation of flotation-plants, including the cost of the different methods, capacities of different units on diverse ores, a discussion of the amount of oil required, and many interesting conclusions as to the 'why' of flotation. He suggested that electro-static conditions are an important factor. During a long series of tests it was observed that the easily-floated minerals were electro-positive and that the unfloated material was electro-negative. It was particularly interesting to learn that a recovery of over 90% was made on the lead carbonate in Tintic ores.

I have referred from time to time to new milling enterprises. They make an impressive showing, as indicating the increasing utilization of lower-grade ores. Seven new mills have been completed within the year, or are under construction; these have a combined capacity of 1700 tons per day. They are the Daly West, Big Four, and Broadwater at Park City, the Knight-Deru, and Utah Minerals Concentrating Co. in the Tintic district, the Cactus in Beaver county, and the Minerals Product Co. at Marysvale. Three mills have added, or are adding, flotation equipment. These are the Silver King Coalition, the Daly Judge at Park City, and the Utah-Apex at Bingham. At Midvale the U. S. Smelting Co. has doubled the capacity of its plant. Six of the ten utilize flotation, either alone or in connection with wet-concentrating equipment.

The production from Park City mines has been curtailed a little because of the low price for lead and silver, but is still over 230 tons of concentrate and first-class ore per day. Three of the companies paid dividends on October 1. The Silver King Consolidated distributed $63,750, the Silver King Coalition, $187,500, and the Daly Judge, $75,000. The Snake Creek adit has been driven nearly 12,700 ft.; the average progress with three shifts of miners is 15 ft. per day, for a cross-section 6½ by 8 ft., and a 3 by 4 ft. ditch. This adit has developed a large amount of water, the flow from the portal being about 8000 gal. per minute.

In the Tintic district lessees are active on the Chief Consolidated, Gemini, May Day, Bullion Beck, Eureka Hill, Colorado, Beck Tunnel, and Yankee Consolidated. The company operating the last-named mine is developing virgin ground in which ore rich in silver, gold, and lead is being found. Shipments from the district average about 400 tons per day, of which a good proportion is valuable on account of its content in zinc. Most of the Tintic mines are equipped with electric power; the mines using this, either in part or completely, are the Victoria, Selma, Gold Chain, Lower Mammoth, Tintic Central, Beck Tunnel, May Day, Yankee, Colorado, Iron Blossom, Gemini, Dragon, and Centennial-Eureka. The Chief Consolidated and Eagle & Blue Bell will soon be operated with electric power.

CARNOTITE MINING IN UTAH.

JOPLIN, MISSOURI, has been producing ores of zinc and lead for more than 50 years, aggregating nearly $300,000,000 in value. This year the production is expected to exceed $20,000,000, which is nearly equal to California's annual yield of gold.

Preferential Flotation

*A patent for the preferential treatment of mixed sulphides has been taken out by Leslie Bradford of Broken Hill. Heretofore a number of processes have been suggested for effecting separation of sulphides from zinc-lead ores by preferential flotation, that is, to obtain lead sulphide and zinc sulphide separately. Such processes, however, are dependent for their effectiveness on the advantage taken of some inherent characteristic of the sulphides by virtue of which they behave distinctively when submitted to treatment by flotation.

The new process consists of treating ores in a medium that wets the zinc sulphide, and which does not wet the lead sulphide or pyrite, and therefore leaves the last-named sulphides floatable while rendering the zinc sulphide temporarily immune to flotation. The lead sulphide or pyrite is thus obtained first as a float concentrate; thereafter the residues comprising gangue and zinc sulphide are treated for the separation of the zinc sulphide from the gangue.

This 'wetting' effect is procured by adding to an acid flotation solution a limited quantity of a substance that is decomposed by the said solution, and produces in this decomposition a reducing gas which is more or less soluble. Thio-sulphates, sulphites, and bi-sulphites are notably so decomposed in a solution of sulphuric acid with the production of such a gas (sulphur dioxide). With practically equal result, sulphur dioxide may be introduced directly into the solution, either as gas brought into it in a current, or added in solution. A similar result is obtained by means of another reducing gas, sulphuretted hydrogen, which may be introduced into the solution in the same way, or may be produced in it by adding sulphides or polysulphides that the solution is capable of decomposing.

In practice, a limited quantity of such a reducing agent is introduced into the flotation solution, prior to treatment of the ore therein with the object of procuring this zinc-wetting effect. The reducing agents are those belonging to the first group, namely, thio-sulphates, sulphites, and bi-sulphites, Mr. Bradford having found them more effective than those belonging to the second group. In the patent specifications certain systematic tests for determining the suitableness and effectiveness of reducing agents for the process are given. In the actual application of the process to a Broken Hill mixed sulphide, containing zinc and lead sulphides, the flotation operation is conducted in a plant of the type described in two previous Commonwealth patents, using the flotation-boxes set in series, and treating ore at the rate of 25 tons per hour. No serious difficulty is experienced in proportioning the sodium thio-sulphate used (the blende wetting agents) so as to ensure the rapid floating of the galena substantially pure, or as a high-grade concentrate rich in silver, and to leave the residue in a condition suitable for further flotation treatment for the recovery of the zinc sulphide.

*Abstract from *Australian Mining Standard*, July 22, 1915.

The treatment is preferably conducted according to the 'froth'-flotation principle. The procuring of the effect aimed at is dependent upon the presence of a frothing agent in the flotation medium, only when a reducing gas is introduced into the medium. It is not dependent on the presence of a frothing agent in the flotation medium when a reducing gas is generated in the flotation medium by a reaction of a substance introduced into it. In some cases it is found that enhanced results are obtained by digesting the ore with sulphuric acid and the reducing agent in a thick pulp, prior to subjecting the same to a flotation operation.

Foreign Trade

The following extract is a translation from an article in the *Deutsche Levant Zeitung*:

"America is beginning to break away from her old-time export methods and is preparing new openings in Russia. Hitherto Russo-American business broke on the credit question. The Americans usually demanded cash payment before export, while American banks denied them every aid in this direction. Now, however, they are not going to let slip the opportunity to supplant German trade, and the National City Bank of New York, according to a Russian paper, has extended the Russian-Asiatic Bank a large credit to cover Russian purchases."

This is of deep interest to several branches of the American mining industry, not only to mining-machinery manufacturers of all sorts, but to producers of copper, zinc, and iron. The immense export trade of Germany was built up through the careful co-operation of manufacturers, banks, and shipping interests, seconded by aggressive salesmanship of men who could speak the language of the country to which they were sent. The German banks were always ready to take the manufacturer's or merchant's paper, with the foreign bank behind the foreign merchant, even if it were a twelve-months' credit. Both made money, the discount at Buenos Aires being 8% when it was 6% at Hamburg. Instead of treating such a man as a person of whom to be suspicious, the banks and the Government were anxious to hear his views as to the preparation of commercial treaties. In another particular American manufacturers are deficient compared with their European competitors. They fail to observe specifications as to orders and packing, treating many of them as absurd, and substituting what they think the foreigner ought to want, instead of what he wants and orders. The United States government is changing to some extent from a distrustful attitude toward foreign business to one more helpful. Reports of U. S. consuls in foreign countries, as to trade opportunities, are being made available for prompt and convenient distribution among business-men.

Peru is likely to become an important producer of rare metals. Antimony, molybdenum, vanadium, tungsten, and bismuth are found there, and some exploration and development of the deposits has taken place.

Hammer-Drilling in Colorado

By E. G. SNEDAKER

The purpose of this article is to discuss a few novel applications of the hammer-type, air-feed, stoping-drill to the work usually done by means of heavier and more expensive drills of the piston or water-Leyner type. The worth of these has been practically demonstrated in the Isabella, Golden Cycle, and Granite mines of the Cripple Creek district of Colorado. These methods have been developed by the 'leaser' or lessee. The lessee often has little money with which to buy expensive equipment.

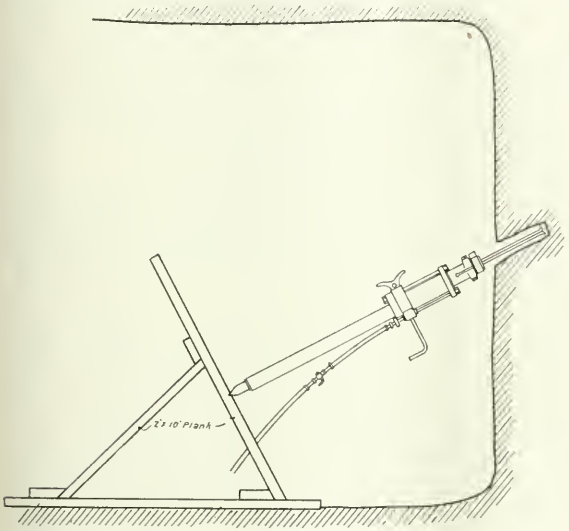

Fig. 1.

He must do his work as cheaply as possible, and employ every device known to save time, in order that his efficiency may be increased. This has raised the standard of all classes of mine work in the district and has led to the development of many devices for saving time, labor, and money. Driving with stoper-machines is one of the most ingenious means of accomplishing this purpose.

The lessee employs as few machines as possible. The major portion of his work is prospecting, by raises and drifts. In many cases he cannot afford a water-Leyner or piston-type machine because of the cost, and the impracticability of using these machines for stoping. The stoper can be used for driving as well as stoping, and is the machine that fits his need. The water-Leyner drill is the standard driving machine of the district, and subsequent comparisons will be made with it. The Waugh No. 16 is the stoper most extensively used in the district, and the drill employed in the driving operations to be discussed.

In the Cripple Creek district, for driving purposes, the water-Leyner stands alone. It presents many advantages. Passing air and water through the drill-steel is important, for the reason that it ejects the rock-cuttings from the hole during the process of drilling, so that the steel is cutting rock with every blow. Further, the fact that the dust is allayed at the same time, improving underground sanitary conditions is appreciated.

Another important feature of the water-Leyner is that it permits the use of an improved system of pointing holes, which when loaded and fired break more effectively than by other systems. The term 'Leyner cut,' applied to a round of

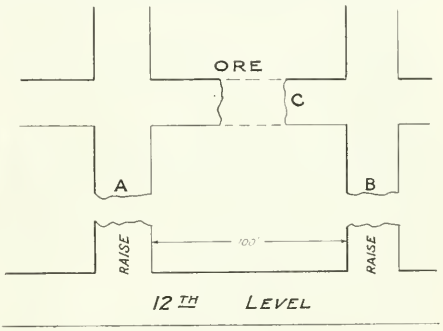

Fig. 2.

holes, has come into general use on account of the many upper or dry holes involved, which can be drilled to advantage only with this type of drill. From the fact that the drill-holes can be pointed exactly as they should be, without regard to angle, direction, or condition of the face of the working, and are not limited in position by the unwieldiness of the machine, as is the case with piston-drills, much less powder is required and the same breaking effect can be obtained with fewer holes of smaller diameter.

Waugh Stopers. It can be said that Cripple Creek is the home of the Waugh machine. It is probably true that more of them are in use in the district than all other machines of a similar type combined. For this reason, therefore, it is desirable to describe, briefly, the essential features of this drill.

The special feature of the sinking and driving drills, No. 8-D and 3-D, is the automatic tappet, which regulates the pressure in the air-feed cylinder, so that the drill will rotate easily. The duty of the air-feed cylinder is to keep the drill-steel against the bottom of the hole, where, by constant pressure, it extends as the hole is deepened. An air-feed cylinder with

sufficient area to keep the drill-steel against the bottom of the hole, when driving above the horizontal, would be found altogether too great on a down hole, when, in addition to the pressure in the air-feed cylinder, is added the weight of the machine and drill-steel.

The following is a brief explanation of the working of this automatic tappet, or regulator. There are two annular grooves, one inch apart, around the small end of the tappet. These grooves register with parts in the wall of the barrel that connects with the air-supply in the air-feed cylinder, and automatically regulate the pressure in the air-feed cylinder according to the hardness of the rock being drilled. This varying pressure is obtained by the shifting of the tappet, caused by the recoil of the piston-hammer. In drilling hard rock, this recoil is more accentuated than when drilling softer rock, and the position of the tappet is governed accordingly.

The model 16-V stoper, the machine used in the comparison, is a heavier and more powerful machine than the 6-V or 7-V, and is suited for drilling in all classes of hard ground. With it 1⅛-in., or even 1¼-in. steel may be used to advantage, where deep holes are required. However, inch steel will be found to stand up well in this machine, if the ground is not too hard.

The air-feed cylinder-nut, through which the air-feed piston works, is of the internal type, and is case-hardened. The air-feed piston is of cold-drawn steel tubing, fitted with double cup-leathers. The oil-reservoir of the automatic lubricating device is in the handle, the machine receiving while running a constant and adequate supply of oil. The diameter of the 16-V piston hammer is 2¾ inches.

Driving With Stopers. The column has often been used in connection with stoper-drills for driving, a special column being manufactured for this purpose. This, however, presents the disadvantages that the miner endeavors to avoid, namely, expense and time in setting up and changing the position of the drill. The methods discussed eliminate this time-consuming factor.

One method of applying stoper drills to driving is by means of a sprag. This sprag is placed 4 to 6 ft. from the face and about 3 ft. from the bottom. A loose 2 by 10-in. plank is allowed to rest against the sprag and the bottom, and is used as a base for the drill. This is the most primitive method in vogue and answers the purpose although it has several disadvantages. First, it is necessary to have a sprag of suitable length. The width of the drift necessarily changes from one shift to another, and a sprag that may answer the purpose one day may be too short or too long the next. Second, it is not always possible to place the sprag in the position desired, because of the unevenness of the walls.

Another method, which is a modification of the one just described, but better, is the simple A-frame (See Fig. 1). This is constructed of a 2-in. plank and is held in position by a sprag across the drift, as shown. The sprag has to be moved once or twice during a round, but this does not take much longer than changing the height of the arm on the column of a piston-machine. All the holes except the lifters are given an upward slope; they are put in nearly horizontal and cleaned by a blow-pipe connected with the air-supply. This method, while superior to the first, still possesses many disadvantages. First, it presents the same sprag difficulty as in the first case. Second, the A-frame is cumbersome, unwieldy, and liable to breakage.

Another example of the ingenuity displayed by lessees in keeping down operating and equipment costs may also be seen at the Granite mine. Two miners had a lease on one of the lower levels. Their work was entirely stoping and raising and their drill-equipment consisted of air-feed stoping-drills. They drove the raises *A* and *B* (Fig. 2); owing to heat and bad air, and also to assist in opening the stope, they decided to drive the drift *C* from *A* to *B*, thus giving an opportunity for ventilation. They could not, as is often the case, afford to purchase a driving-drill, but with the aid of a simple foot-plate, they found that they could use a stoping-drill to put in holes at all angles, from the vertical to the horizontal. This foot-plate (Fig. 3) was made of a sheet of ⅜-in. steel with ears turned down to act as spikes and hold the plate upon a plank. To this plate was riveted a piece of angle-iron bent to a U shape.

The drill used for this work was the standard Sullivan stoper. The rock was hard granite. The cutting speed was from 14 in. per minute in vertical holes to 8 in. per minute in horizontal holes. A blow-pipe was connected with the air-supply and used to clean the cuttings from the flat holes.

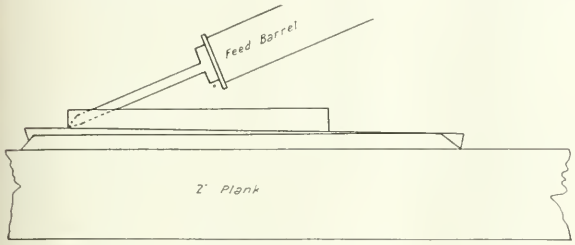
A more permanent support, giving a greater latitude of stretch, has been devised by Lee B. Kellum, master-mechanic at the Isabella mine. The first bar developed (Fig. 4) approximates closely in design the feed-arrangement of the Waugh stoper-drill. That is to say, the 'stinger' or feed-bar moves out of the barrel in the same manner as a piston. This piston is actuated by pressure from the air-line. The barrel is 2½ ft. long with a diameter of 2 in. The feed-bar is the ordinary one of a No. 16-V Waugh stoper, 2½ ft. long. This allows a stretch of from 2½ ft. to 5 ft. It is obvious, if a drift wider than 5 ft. is to be run, it is only necessary to make the barrel of the bar longer. This bar is satisfactory in every way, but the inventor has improved it by using standard pipe-fittings.

The method of 'setting up' is unique, especially when compared to the usual 'set up' of a drill using a column. It is necessary to shovel back for 4 or 5 ft., in order to provide an open space near the floor of the drift, in which to place the bar. Two small hitches are cut in the wall directly above each other and in such a position as to fit the claw of the bar. The water-tank is placed in a convenient position. The air-hoses are attached in their proper places, the main line to the three-way valve and thence to the drill, and an auxilliary line to the water-tank.

This is an ordinary galvanized-iron water tank of the Leyner type, about 4 ft. long and 1 ft. diam. It is fitted with two valves and a plug in the top. One valve to attach the air-line from the bar and the other valve

to attach the line to a blow-pipe, which is used to allay any dust that may become troublesome in drilling. The plug is to allow filling. The air, on being admitted to the tank, forces the water through the blow-pipe in a fine spray. This spray is directed at the hole and prevents dust from accumulating.

An ordinary closed iron chain, of inch links, is placed around the bar, as shown in the accompanying sketches (Fig. 4 and 5). When these preliminary operations have been completed and all connections tightened, the air is turned on by the valve at the drill and the tank closed. The air enters the bar, which expands against the sides of the drift. The claw fits into the hitches and prevents rotation, which tends to occur when actual drilling starts. The stinger or sharp end opposite the claw furnishes the other support against the opposite wall.



SIDE ELEVATION

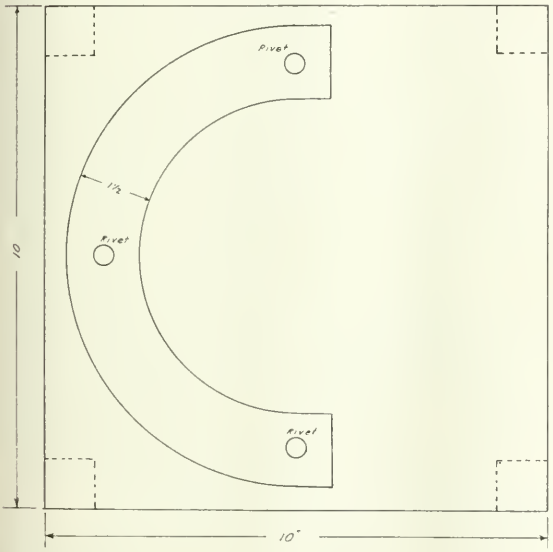


Fig. 3.

Up to this time all that is accomplished is to furnish a base for the stinger of the stoper-drill. As is well known, it is necessary to furnish such a base for this type of drill, whether false or natural. In stoping, the stinger rests on the filling of the stope, or on a platform built for such a purpose, and as the drill is working vertically, or nearly so, the drill needs no support. But in driving with the stoper a base must be supplied that will remain stationary and allow the drill to advance on the hole as in stoping, depending for horizontal support on the rigidity of the base and the depth of hole.

The air-line is now connected to the drill in the usual manner. The point of the stinger is placed in one of the links of the chain around the bar. This depends upon the distance required between the face of the drift and the butt of the drill and to what length the machine will extend. It is possible to have the bar close to the face and by placing the stinger in a suitable link, extend the drill 6 to 8 ft., the stinger being several feet behind the bar.

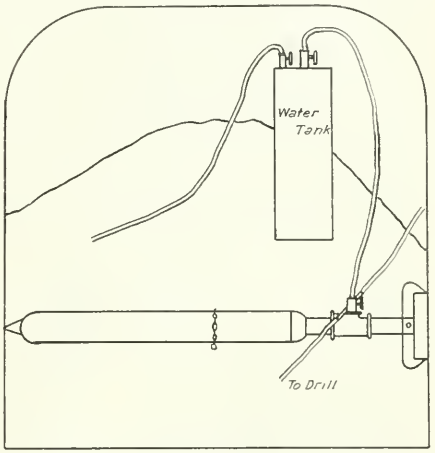

Fig. 4.

After the stinger has been placed in the proper link, the drill is pointed in the desired direction and the air turned on. From this point the operation is identical with the method used in stoping. Rotation is by hand.

It will be seen that if the bar is placed near the bottom of the drift it will permit the drilling of upper holes only. Therefore, as drilling progresses and the operator desires to drive a horizontal hole, he merely raises the bar the desired height and resumes drilling.

One should not lose sight of the fact that the drill is not supported in the middle. Its sole support depends upon its rigidity, the bar, and the depth of the hole.

Before taking up the number of holes drilled, and details of time and cost, it might be well to consider a few advantages and disadvantages of this method, in order that one may understand some of the differences in the time of changing steel, etc., which will follow.

It can be readily seen that as the holes become more nearly horizontal, the more precautions will be necessary. As this drill is rotated by hand and the steel is not fastened in the chuck, difficulties will arise when horizontal

or down holes are drilled. In drilling such holes the steel often must be removed by aid of a wrench. This changing of steel takes time and may become serious in broken ground.

Under conditions a little below the average, very fair figures were obtained with regard to changing steel and the length of time required for drilling holes. The air pressure was 60 lb., which is 30 lb. less than the average.

An upper hole, 4½ ft. deep, was drilled in 7½ min., using three changes of steel, showing a drilling speed of 7.2 in. per minute.

As this was an upper hole, no difficulty was encountered in removing the drill from the hole. On a down hole there is always the possibility of sticking and no fair figure can be given. The number of holes drilled will vary with the ground, but a fair figure is about 15 holes per round, breaking from 3½ to 4 feet.

It has been possible, by working in a drift and a crosscut to break as high as 9 ft. on one shift, the operator drilling a round in each breast with the same drill. To do this would require a steady air pressure and no break-downs.

Using contract labor and a Waugh No. 16 stoper the following driving and cross-cutting was done in a latite-phonolite or spongy volcanic tuff.

Month.	Footage.	Cost per foot.	Cost.
October	63	$2.00	$126.00
November	37	2.00	74.00
"	93	2.25	209.00
December	49	2.25	110.25
	242		$519.25
Average cost per foot		$2.14	

The above costs are remarkably low. The footage for October, 63 ft., was made by two men working 15 shifts; the machine-man being paid $4 per shift, and the shoveler $3 per shift. During the four months the two men worked 52 shifts and drove 242 ft., 117 ft. of which was drift and 125 ft. was cross-cut. The total cost per day was $9.98, which includes drilling, blasting, 'mucking,' tramming, and caging.

The following figures, obtained from the superintendent of the Golden Cycle mine, serve as a comparison with those given. A 2¼-in. water-Leyner drill was used. Contract labor was employed, and the figures also include powder, fuse and caps.

Following are the costs per foot of driving in the Golden Cycle mine, Colorado: $2.69, $2.77, $2.76, $2.72, $2.72; total, $13.66; average cost per foot, $2.73.

A comparison between the cost by the stoper and that by the Leyner shows an advantage in favor of the stoper.

It is apparent that this method of using stopers for driving saves first cost and up-keep.

The advantage of these drills in driving, as compared to the Leyner and similar types, lies in their light weight, ease of handling, saving of labor, cheapness, and ability to perform more work.

[The above description of ways and means employed in the Cripple Creek district are all the more interesting when it is remembered that it was at tunnel-driving in homogeneous granite in Colorado several years ago that the remarkable efficiency of the new-style drills and drilling methods first attracted attention. It was in the West that most of the modern drills and sharpeners were devised, not in some factory or experiment-station near New York, in spite of the fact that high-priced drill-experts ruminate over their little inventions there. The low costs of driving tabulated above indicate what men working for lessees can do, and are an agreeable revelation of the adaptability of the stoper-drill. The use of stoper-drills is somewhat of a local question; for instance, there are few of them in the Lake Superior copper region and their introduction in the Alabama iron-ore mines has been slow. On the other hand, in Colorado, on the Marquette iron range, and in many other districts, a tremendous number of stopers are in use.—Editor.]

Public Mineral Land. In the Report of the Commission on Industrial Relations, the Director of Research and Investigation, Basil M. Manley, suggests that the Commission recommend:

1. The enactment of appropriate State legislation providing that where communities develop, even upon privately owned land, the powers of the civil Government shall not be interfered with, nor shall the rights of access to the residence of any person be restricted, nor shall the rights of persons to come and go unmolested, to speak freely and to assemble peacefully, be interfered with or considered to stand upon a different basis from the rights of persons in other communities.

2. In the case of public lands containing timber or minerals, which are now or may hereafter come into the possession of the Federal government, it should be provided by statute that neither the lands nor the mineral rights should under any circumstances be sold, but should be used only upon lease for a limited term, such lease to contain as a part of the contract the conditions with regard to the rights of inhabitants as recited above and such lease to be forfeitable without recourse in case of the infraction of said conditions.

Platinum producers in the Urals, Russia, are now obliged to mortgage their product to the Ekaterinburg banks, because the French company that had a practical monopoly of platinum-buying and which was itself a large producer, was unable to continue its purchases. Moreover, the demand for platinum is slack. The Ekaterinburg price for small quantities of platinum was $28 to $29 per ounce. The amount of platinum mortgaged to the Ekaterinburg banks is estimated at 40,000 ounces. The output for 1915 will be much less than in former years.

The average death-rate of employees in the gold mines of the Rand for the last year was 3.22 per 1000. There were 564 persons killed underground, of which number 145 met death through explosives, and 110 through misfires.

HAMMER-DRILLING IN COLORADO.

The Natural Taxation of Mineral Land

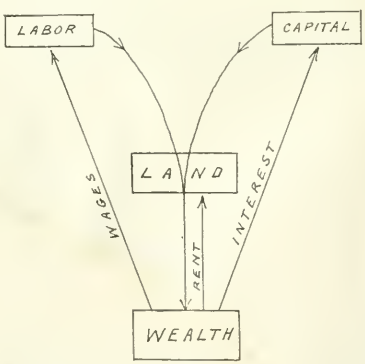
By R. B. BRINSMADE*

Introductory. Since my letter to the Press on mining law[1] was published in 1911, the ideas then expressed have begun to be embodied in American legislation. The enactment of the Alaska Coal-land Leasing Act and the passage of the Oil-land Leasing Bill in the Lower House, by the 63rd Congress, are encouraging signs of a national awakening as regards the legal needs of the mineral industry.

The continuance of the leasing system for mineral school-lands, as on the iron ranges of Minnesota and in the coalfields of several Western states, are signs that the individual States, too, are beginning to consider the interests of society as well as of first-comers, in their administration of natural resources.

By the adoption of the leasing system of Spanish America for all the remaining Federal mineral lands, the public interest can be henceforth conserved, but even this reform would not affect the vast area of mineral land already acquired by Federal patent or by the freehold surface titles of the Eastern states. The evils of land speculation and monopoly, which are now so prevalent in many mineral regions as to bar the independent prospector from making explorations and the small capitalist from entering mining, are not incurable but can easily and legally be remedied. A beginning was recently made by the adoption in Michigan of a new system of mining assessment[2]; but to be completely effective this reform must be supplemented by a more rational theory of taxation than the prevailing one.

Before presenting my practical proposals, I beg leave to explain some of the principles of political economy upon which they are based:



In the accompanying diagram, Labor, with the assistance of Capital, works on Land to produce Wealth, which is then distributed: Wages goes to Labor, Interest to Capital, and Rent to Land. This simple diagram can be fitted to any productive industry, no matter how complicated, care always being taken to use its seven terms in their exact economic technical sense, as follows:

Land signifies the earth and its attributes, or natural resources; and it includes all such material gifts of Nature as can be monopolized. The value of Land is calculated after deducting all improvements due to Labor and it includes five main classes: Agricultural, Forest, Townsite, Mineral, and Public-utility franchise. In the technical sense, Land is not Wealth but merely one of the essential factors in production.

Wealth signifies any labor-product or handiwork of man; it includes buildings, tools, machinery, improvements, commodities, etc.

Capital, when used popularly, often includes both Land and Wealth, but technically it is restricted to the latter when used productively.

Labor signifies any mental or manual effort of mankind that aids in producing wealth.

Wages, Interest, and Rent are the rewards allotted to Labor, Capital, and Land, respectively, from the Wealth output. In popular language, the total income of a business man is often called 'profit,' but a little consideration will suffice to separate it into its three economic portions: wages, interest, and rent. Popularly also Rent may include the hire of both buildings and land (technically called 'real estate') but true rent means the income from land alone.

Dual Nature of Property. Given the same quantity and quality of labor and capital, the wealth output will vary with the productivity of the land utilized. This difference in the productivity may be due to geologic causes, which influence the fertility of the soil or form ore deposits, or to location, as in the case of townsites or public-utility franchises. As the benefits arising from either geology or location are not due to the individual landlord, he should not be allowed to monopolize them except on condition that he return to society an adequate compensation. Modern legislators, however, have hardly begun to recognize this self-evident principle and the indiscriminate confusion of property in land with property in true wealth, which prevails in existing laws, is the cause of most industrial evils.

In each industry there exists 'marginal' land, that is, land whose product leaves no residuum or rent after wages and interest have been paid. This marginal land varies in quality with commercial activity, but it may be described as the leanest land that has to be worked to

*Consulting engineer, Puebla, Mexico.

1'Texas Mining Laws,' Mining and Scientific Press, April 15, 1911.

2'Appraisal of Mining Properties.' Report of Michigan Tax Board for 1911.

satisfy the current requirements of the market. I can now state Ricardo's Law of Rent: "The normal rent of any land is got by deducting the produce of marginal land from the produce of the land in question, the same labor and capital being applied in each case."

In popular speech, 'speculation' means taking a risk of gain or failure, even in ordinary trade, but in this article it signifies the holding of property out of use for the purpose of obtaining an enhanced price. It is evident that land lends itself easier to speculation than wealth because it is imperishable and, being fixed in quantity, tends to advance in price as population and business increase. Speculation in wealth, on the contrary, is only profitable where the whole floating supply can be cornered for the purpose of obtaining, temporarily, that unearned profit which uncontrolled private land-ownership, in growing countries, tends to give naturally and continually.

The term 'promoter' is not synonymous with 'speculator;' the former is a necessary factor in starting all new enterprises for the development of land; while the latter is purely an industrial parasite, the modern robber-baron, who with paper titles blocks every road to production.

With a given quantity of labor and capital in a country, it follows that the greatest output of wealth will be obtained by applying them to the most productive lands. If a part of the better lands are held idle by speculators, the forced resort of the corresponding labor and capital to inferior lands will result in a lessened output.

Holding superior land idle tends to decrease the productivity of labor by causing it to be applied to a poorer quality of marginal land than would be necessary were the whole area of superior land in production before recourse was had to an inferior quality. Therefore speculation in land will always reduce wages; and, if carried on extensively, will artificially reduce wages in a new and thinly-settled country to the level that they would only have reached, normally, after a dense population had arrived for settlement.

The rate of interest (independent of cost for insurance of capital) is fixed by the *extra* output obtained by applying capital to marginal land. Hence every decrease in the quality of marginal land, produced by the holding idle of superior land, means a decreased advantage from the use of machinery, and consequently a less hire or interest for it.

Although speculation decreases the output of a country, the net yield or rent from any given tract of superior land is increased, since there are less wages and interest to be deducted from the gross product. The market-value of all superior land (which is simply the capitalization of its net yield, if developed) is correspondingly increased by the rise in rent caused by speculation.

Though supply and demand may name the temporary price of a commodity, its average price is fixed by the cost of reproduction on marginal land[3]. Speculation, therefore, by artificially lowering the quality of available marginal land will increase prices and the cost of living.

Land Monopoly. Capital and labor are movable, capable of being reproduced and therefore essentially competitive in nature. Land is immovable, fixed in quantity; therefore its control implies exclusiveness and monopoly. Thus the land-owner has the ultimate control of production and is also the residual legatee of the wealth-output, after the claims of labor and capital have been paid.

As competition tends to cut both wages and interest down to the lowest living rate, the residual and monopolistic factor, or rent, tends to absorb the whole gain proceeding from improved methods of production.

From this fact, that landlords are able to demand the cream of the wealth-output, arises the condition that most of the world's capital gravitates to the possession of the great landlords. As these latter prefer to be called 'capitalists' rather than 'landlords,' many reformers have mistaken capital instead of land for the controlling factor in production. This mistake was promulgated by Carl Marx in 1873 in his first volume of 'Kapital' dealing only with manufacturing; but when it was corrected in 1893 by the publication of the posthumous third volume of 'Kapital' dealing with land, it was then too late to alter the economic program of European political socialism, which had then used Vol. I of 'Kapital' as a Bible for 20 years.

It is the popular impression that a large corporation or union of such, called a Trust, is necessarily a monopoly and therefore an industrial danger. This erroneous conception arises from the confusion of monopoly with bigness; the distinguishing feature of monopoly is not bigness but absolute control of the object. Land, as now owned in modern nations, is a monopoly only because the holder can keep it idle or abuse it, at the risk of little or no penalty; the exclusive individual possession of land is not a social damage if its proper use is assured.

In normal competitive conditions, rent is not a factor in fixing prices, since marginal land is rentless. But for certain commodities, such as diamonds and anthracite[4], where the fund from which they can be produced is so limited in quantity as to be easily cornered by one company, there ceases to be any rentless land at all. For with all diamantiferous land in control of the diamond monopoly, the price of diamonds is fixed at a point to secure the maximum annual profit; and this artificially fixed price is quite independent of the cost of reproduction in the marginal diamond mine and might often yield a rent for such a mine.

Ethics of Land-Ownership. A modern nation is organized on a purely territorial basis; it depends upon the social grouping or location of its inhabitants. The control of land is thus the foundation of civilized society. Under the feudal system of medieval Europe,

[3] 'Political Economy' by J. E. Symmes.

[4] 'King Coal' by L. L. Redding in *Everybody's Magazine*, 1912.

the proprietors of land and the civil governors were the same persons, and land rents and land taxes were synonomous terms.

In feudal England, the land-owners were the gentry or governing class; they not only gave their own time gratis to the State but supported from their rents the public services of defense and justice, while charity and education were sustained by the church estates. The introduction of freehold tenure and indirect taxation enabled the gentry gradually to shift the fiscal burden of government onto the unprivileged producing classes; but even now in England the landlords recognize some obligation to the State, for they fill with zeal many unpaid or underpaid public offices. The adoption, however in the United States of the English aristocratic system of private land-ownership along with political democracy (and officials paid from the taxation of wages and interest, rather than rent) was an anachronism whose evil effects are every day becoming more apparent.

From my citations of economic principles, it is clear that the existing anachronism can be fully corrected by restoring the original obligation of private landholding, that is, the payment of the whole cost of government from the only legal unearned incomes, those from rent. Not only would this change decrease the public burdens of both low-grade mines and working miners but it would paralyze land speculation and monopoly, which are more injurious to society than even the inequitable distribution of rent.

Practical Proposals. I now beg leave to offer a plan for the application to mineral land of the only equitable tax system, that on land-values, which is called the 'natural' system because of the curious fact that rent, and consequently a percentage tax on it, rises and falls with the necessary expenses of government, which vary directly with population and business activity. As rent is a residual factor, it has normally no effect on prices; and a tax on it can thus neither raise prices nor be shifted to the ultimate consumer.

As the plan involves direct taxation, it would be applied by State law except in the Territories. Its ideal is twofold: first, to tax the mineral industry only on its land-values; second, to encourage the largest development consistent with human safety and the full utilization of mineral deposits. The application of the plan will be discussed in four proposals:

I. Separation of surface from mineral rights.

II. Mineral areal tax.

III. Mineral output tax.

IV. Abolition of taxation of capital and labor.

Proposal I. Separation of Surface from Mineral Rights. This proposal requires a new statute for the separate classification of surface and mineral property in the official tax-lists. It would involve no change in ownership and would simply separate all present land-titles into two portions: one to all surface rights, and the other to all rights over the minerals specified in Proposal II. There would be no need for separating land-rights in existing deeds or records; and such separation would only be required for all sales post-dating the new statute.

A portion of the separation statute should follow Australian practice, by declaring mining a public use, and arrange a cheap, quick, and simple procedure for the acquirement, at its appraised value, of such surface areas as would be necessary for the extraction of minerals lying under separate surface ownership[5].

This proposal involves an areal tax on all the underground rights in the State, whether any mineral is supposed to exist under any given area or not. The areal-tax should be high enough to stimulate the development of minerals and to discourage speculation of either the hold-up or monopolistic type. But it should be low enough to allow active operators to profitably carry a reasonable mineral reserve for the future and to have no compulsion to exhaust their ground by wasteful methods.

The exact rate per acre to achieve these ideals would naturally vary with every individual deposit, but such refinement would be needless, and in practice it would suffice to classify all mineral deposits into two groups: the first would include all deposits in place, of gold, silver, lead, copper, zinc, tin, iron, and other metals; and the second would comprise the surface placers of gold, tin, and other metallic minerals, and the deposits in place of combustibles (coal, petroleum, gas, etc.) refractory clays, tripolite, marble, sulphur, phosphates, and salines.

As a general annual rate for the areal tax, I suggest $4 per acre for Group I and $2 per acre for Group II. These rates are slightly lower than the labor tax of $5 per acre now exacted from holders of Federal metallic claims, and slightly higher than those of Peru, which are $3 per acre for Group I and half as much for Group II.

These rates should be increased for specially rich lands, like the Mesabi iron range or the Scranton anthracite field, and decreased for unusually lean lands, as the Southern clay-ironstones and the Texas lignite districts.

In order to give present land-holders sufficient time for the exploration or sale of their mineral rights, the full areal rates should be reached only after a transition period of 10 years, increasing the tax meanwhile annually 10% of the final rate. The payment of Group I would conserve all rights to both groups, but the payment of Group II tax would protect the rights to that group alone.

The inauguration of the areal tax would result in a scramble among land-owners to either develop their own minerals or sell them. This scramble would not only speedily reduce the price of minerals in the ground but also for the consumers, since it would raise the quality of available marginal land and thus decrease the cost of production.

For mineral rights of no present commercial value,

[5]'Mining Laws of Australia and New Zealand,' by A. C. Veatch, U. S. G. S. Bulletin No. 505.

the land-owners would usually refuse to pay the areal tax and such rights, if no purchaser were found at the annual tax-sales, could be resumed by the State without expense. Such valueless rights would include both land of no geological probability and land of a sub-marginal quality. The resumed land of the latter class would be available for future development by the public-leasing system; and even now would act as a check on private land monopoly by being freely open to prospectors for leasing.

Not only could the Federal government resume large areas of commercially valueless mineral rights in the Territories by the areal tax, but it could at once recover vast areas of valuable underground rights in both States and Territories by adopting the suggestion of A. C. Veatch:

"If Congress should enact at this time that in every case, both in the past and future, where the purchaser of land from the Government made a non-mineral affidavit, that all minerals belong to the Government, it would leave each man with exactly what he swore he was getting and exactly what he paid for. Such an act would be eminently just. In individual cases it would be less severe than the attempt that is now being made in the Western states to recover to the Government, by lawsuits, mineral land acquired under the agricultural-land laws. In these cases the Government seeks not only the mineral values but the surface values as well. It endeavors to take from the patentee everything; it asserts that the patentee has been a perjurer and has defrauded the Government.

"Under the plan here suggested all such points of difference and all such charges vanish. The oath is regarded not as a perjured statement, but as an honest indication of intent and desire. The claimant's statement that he was acquiring land only for agricultural purposes is made binding on him. The charge of fraud likewise falls; the Government has under this solution not been defrauded; it has sold the agricultural values and received the usual price therefor. The patentee retains what he has bought; the Government what it did not sell. This is a solution of the matter of Western 'mineral-land frauds' which can but appeal to all men as entirely fair."

As the selling-value of agricultural and townsite lands can easily be ascertained, the American custom of assessing this value (or the capitalized rent) for taxation is preferable to the European method of assessing rent itself; because by the latter scheme any land held idle for speculation, and therefore yielding no rent, would pay no taxes.

But in the case of mineral lands no accurate valuation can be made except in the two special cases of surface deposits, and of coal, iron, and other bedded deposits, which can be economically explored by boring. For the sake therefore of uniformity and simplicity, I deem it advisable to assess mineral lands on their rents, rather than on their selling-values, and to offset the consequent encouragement of speculation by the areal tax.

The proposed output-tax, being a tax on rent alone, will not be levied on the gross but on the net output of mineral; and it will therefore correspond to the royalty now collected by private landlords from those mining operators who furnish everything for production except the land itself, as in many cases on the iron ranges of Lake Superior or in the zinc districts of Missouri and Wisconsin. The output-tax would be the same fraction of the 'true' royalty and the surface-land tax would be of the true rent of agricultural land. The tax would be paid entirely by the land-owner, except in those leased mines where the landlord's royalty is less than the true royalty; in which cases the benefited lessees would pay their proportionate share too.

The true royalty of any mineral deposit is the net profit remaining after interest and sinking fund on the cost of betterments (as well as operating and maintenance expenses) have been deducted from the gross earnings. It does not include any deductions for 'interest' or amortization on any sums that might have been paid to former owners for the minerals themselves. In other words, the true royalty is the unearned income (or land-rent of the Trinitarian diagram) and in order to make its calculation accurate it would be necessary for all mineral producers of any size or permanence to keep their accounts by a uniform system, prescribed by, and open to the inspection of, the State tax-commission.

Proposal IV. The Abolition of Taxation of Capital and Labor. As Fillebrown estimates that only 40% of the present total revenue (Federal, State, and local) is collected from land-values, it is evident that the first three proposals would not inaugurate the natural tax for mineral land unless accompanied by a shifting of the incidence of taxation. If all public revenue were raised from land-values, it would imply an increase in the existing direct-tax rates of 150%, and an absorption by the Government of 40 to 50% of the land-rent now going to private parties; but, as an offset, the latter would pay no more direct or indirect taxes on their capital or labor.

If the Federal tax system were left intact, the necessary increase in the direct-tax rate, to raise all State and local revenue from land alone, would be about 100%. But these increases would not affect all property uniformly, since land has been valued separately from improvements in only a few localities; and these re-valuations have shown that usually rich land is under-valued and lean land is over-valued under the old combination method.

A State's first step toward the natural system would be the exemption of chattels and real-estate improvements from taxation. The process of exemption should be distributed over several years (as is now being done at Pittsburg and at Scranton, Pennsylvania) so as not to disturb unnecessarily mortgage and other contracts based on speculative land-values.

The application of the natural system to Federal taxation would merely involve a return to the taxing scheme of the Confederation Articles of 1781, which required the collection of all Federal revenue from the State treasuries, each State paying a quota in proportion to its assessed land values.

General Effect. If the plan were immediately inaugurated the mineral producers would pay the Government no more taxes than at present and they would be relieved, both as producers and consumers, of the vast tribute now wrung from them by land speculators and

monopolists. Except for the nominal areal tax, there would be no further taxing of mines in the development stage or of producing mines that actually yield no net profit above operating costs and interest and amortization of betterments.

The plan thus would indirectly subsidize prospectors to perform the needed service of opening new mines, and public revenue would not suffer, for it would dip deeply into the huge net incomes of the bonanza mines, which are now greatly under-taxed.

The resumption by the State of low-grade mineral rights, through the areal tax, would throw a vast area open to prospectors. This resumption and the royalty-tax would also make more ethical the work of the State geologists, whose efforts now, though mostly paid for by taxes on capital and labor, conduce only to the financial benefit of private land-owners. Under the plan, State-aid might be rationally and justly offered to prospectors, as in Australasia, where rewards are paid for the discovery of new districts and public drilling-plants and testing-mills are maintained.

The general effect on mining of a movement toward the natural-tax system would be to increase both wages and interest; not only by throwing all taxes onto rent but by increasing the gross output, owing to the higher grade of marginal land available, due to the release of big speculative holdings now idle. The only class that would feel the change would be hold-up speculators, whether poor or rich; the poor gamblers would have to go back to honest work while their rich counterparts would be henceforth forced to employ their talents and money in production, as their tribute-levying on the activity of others would be no longer profitable.

Answers to Objections. To forestall any objections to the plan on the grounds of radicalism, injustice, or impracticability, I beg leave to remark as follows:

While pleading guilty to radicalism, I wish to inquire if scientific reform can have other than a radical (root) foundation? It is just here that lawyers and engineers differ in method of thought; most of the former look only at the past, and, being afraid of first principles, they can only construct patchworks, while the latter must either understand the laws of Nature or ingloriously fail.

Our existing land and taxation laws have descended to us from an aristocratic past, but this fact is disregarded by most of our legislators, either from selfishness, venality, or from an ignorance of history and political economy. Scientific economic reforms must be preceded by an improvement in the legislative personnel and this can best be attained by adopting small unicameral legislatures and proportional representation; the former will enable the payment of attractive salaries and the latter will permit both intellectual independence and a public career, now almost incompatible[6]. The change from traditional to scientific methods in many law-schools is a hopeful sign for future legislative progress. The plan may interfere with vested wrongs, but will it insure any vested rights? Conservatives have opposed, on ethical grounds, every previous attempt of mankind to free itself from venerable, but unjust and oppressive, institutions. If any reform be founded on natural law and social justice it should be adopted as an ideal, and put in practice as soon as expedient, irrespective of existing institutions, however hoary. Has ethics any higher ideal than "Industrial rewards should be proportional to services rendered to society," and can this ideal be attained otherwise than by the natural tax?

By private-land privilege and monopoly the producers can be as completely enslaved, economically, to the idlers as by chattel slavery[7]; and even engineers not infrequently are made to feel the power of vested wrong-owners over their freedom as citizens. Should not miners, the most potent of wealth producers, begin to devote more attention to the consideration of wealth distribution, which is chiefly a political problem?

Vested wrong can be justly abolished without direct compensation to present beneficiaries, but the change should be gradual enough not to unduly cause hardship to innocent persons. Thus chattel slavery was abolished in Brazil by gradual uncompensated emancipation; a juster method for taxpayers than the purchase scheme of the British colonies, and a fairer plan for slaveholders than the war-measure emancipation of the United States.

The plan involves little not already in successful use elsewhere. In most countries under the Napoleonic code (Latin Europe and America[8]) and in much of Australasia, underground rights are separated from surface rights and are assessed an areal tax and an output-tax. Both Canada and the Transvaal share in the net profits of many private mines; while the resumption of Proposal II is less drastic than the existing laws of Tasmania and New South Wales, which permit the State to resume any undeveloped mineral land by compensating its owner for surface values alone.

[6]'Proportional Representation' by J. H. Humphreys.

Gold Output of Australia

For the first eight months of the current year the yield was as follows, in fine ounces:

State.	1915.	1914.	1913.
New South Wales	90,833	82,852	96,576
Queensland	171,467	157,280	178,167
*South Australia	4,000	4,000	5,500
*Tasmania	11,360	17,500	22,266
Victoria	215,763	285,069	290,576
Western Australia	804,256	813,221	857,335
Commonwealth total	1,297,679	1,359,922	1,450,420

*Approximate.

Gold output of the Rand in September was 776,000 oz. For the nine months of 1915 a large increase was made, and the current year should be equal to 1913, the largest on record.

[7]'The Menace of Privilege' by H. George, Jr.

[8]'Mexican Mining Laws,' Trans. A. I. M. E., Vol. 32; 'Colombia Mining Laws,' Trans. A. I. M. E., Vol. 28; also publications of Pan-American Bureau, Washington, D. C.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Over 10% of the coal production of the United States is used for domestic purposes.

Owing to the curvature of the earth, a mountain 5717 ft. in height would be invisible at the distance of 100 miles viewed from the sea-shore.

Gasoline engines cannot safely be employed underground in mines, unless the exhaust gases can be conducted by pipes out of the mine.

Mirages are due to refraction and reflection from layers of air of different density, such as are often formed above a wide expanse of level country in warm weather.

A carelessly used ladder is a dangerous thing; it is stated that slipping ladders cause the death of 6000 and injury to 200,000 persons every year in the United States.

Fossils are considered an aid to coal prospectors. Certain fossils indicate the presence of high or low-grade coals. This is especially true in the Grand Mesa coal-bearing region of Colorado.

An ordinary gauge-glass, nearly filled with water, and plugged at each end with putty or some cementing material, will serve as a level when none other is available. The bubble can be made any length desired.

The stamp-sand or tailing from Michigan copper-mills of which there is such a tremendous amount in Torch and Portage lakes is utilized to advantage in the manufacture of concrete, asphalt, and roof-shingles. Steamers have been taking large cargoes of this sand to ports on the lower lakes.

Mass copper occurs in six levels in the Trimountain mine in Michigan, its thickness varying from paper to several feet. Extraction by chisels and other tools is slow and expensive, so cutting the copper by means of an acetylene torch is to be tried. The mass copper is sent direct to the smelter.

Slime settlement and filtration at the Leonesa mine, Nicaragua, was hindered by the clayey matter in the decomposed walls of the vein, but mechanical thickeners greatly helped the problem. The capacity of the stamps was increased by making the depth of the discharge of the mortar-boxes greater.

The Sons of Gwalia stamp-mill and cyanide-plant in Western Australia was recently altered at a cost of $154,000. It was estimated that the cost of $1.80 per ton and residue of 90c. per ton would be reduced to $1.56 and 66c. respectively. Actual results are $1.44 and 60c. per ton, equivalent, on an output of 13,500 tons of ore per month, to a saving of $106,400 per annum, which redeems the outlay in a trifle over 18 months.

Re-soiling dredged ground made good progress in Victoria, Australia, last year, according to the report of the Sludge Abatement Board just received. By means of advance stripping of soil, silt distributers depositing soil on dredge tailing, and a little leveling, considerable areas of land that grow fruit trees and grain are being reclaimed.

To determine whether wrought iron or steel pipe has been supplied to a mine the sulphuric acid test is reliable. Take a short piece of the pipe, and immerse it in one part H_2SO_4 and three of H_2O for six to eight hours; if the pitting shows a granular structure the material is steel, and if fibrous it is wrought iron. Hammer and chisel, cutting and thread, and emery wheel tests will show which metal the pipe is of in a few minutes.

Strength tests of structural timbers treated by commercial wood-preserving processes, showed the following conclusions, according to H. S. Betts and J. A. Newlin of the Forest Service: (1) Timber may be materially weakened by preservative processes. (2) Creosote in itself does not appear to weaken timber. (3) A preservative process which will seriously injure one timber may have little or no effect on the strength of another. (4) A comparison of the effect of a preservative process on the strength of different species should not be made, unless it is the common or best adapted process for all the species compared. (5) The same treatment given to a timber of a particular species may have a different effect upon different pieces of that species, depending upon the form of the timber used, its size, and its condition when treated.

Radium is extracted only from uranium minerals; it has been obtained from pitch-blende in Austria, Cornwall, and Colorado; from autunite found in Portugal; from carnotite associated with vanadium found in Colorado and Utah, from carnotite associated with ilmenite in South Australia and in Turkestan. The total quantity of radium hitherto produced in the world is about 1½ ounces of a value, at present, of about $5,000,000. The carnotite ores of Colorado yield over 75% of the production since the War; these ores are now marketable only when containing at least 1% of uranium oxide, that is containing one-twentieth of a grain of radium per ton. Carnotite contains both uranium and vanadium, and the Colorado deposits were developed originally for the vanadium content. To test any mineral for radio-activity, wrap a photographic plate in two thicknesses of black paper in the dark, place a key on the paper, and suspend a few ounces of the mineral over the key, the whole being contained in a box that admits no light. Another method of testing is to measure the rate of discharge of a home-made electroscope when the powdered mineral is introduced into it.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

OURAY, COLORADO

Base-Metal Recovery from Ouray Ores.—Camp Bird, Revenue, Mountain Top, Atlas, Wanakah, American Nettie, and National Belle.—Red Mountain District.

Mines like the Camp Bird afford an interesting problem, as regards loss of base-metal contents. In 1913 the concentrate shipped, 525 to 550 tons per month, assayed as follows: Au, 1.91 oz.; Ag, 19 oz.; Pb, 9.9%; Cu, 2.7%; and Zn, 14.5%. There is a custom plant of the Huff electrostatic type at Ouray that could save the zinc. It has never failed to do excellent work on concentrates (there is no mill in Ouray), but it is allowed to lie practically idle. It is stated that Joe Terry at the Sunnyside has been making $1000 per day out of the zinc-content of his ore for the last two to three months. He is putting in more Huff machines, but has made no move in flotation. Mears, Wilfley, and Slattery are doing well with their flotation plant at the Silver Lake mine. Hyde is still at Silverton, and is understood to be looking around for properties where his process might be installed to advantage.

E. H. Platt, formerly at the Revenue mine, and later superintendent of the St. John mine in the Montezuma district, Summit county, whose deal on the Revenue properties with the Tres Forcas Syndicate, London, almost fell through on account of the War, was expected in Ouray last week. It is said that they have made a second payment to A. E. Reynolds, who has agreed to wait till the end of the War for completion of purchase. They may do some work this winter, though rumor again says they contemplate leasing the Camp Bird mill.

There are many reports that the Camp Bird mine is to close this winter, but most of us do not believe it. Some of the men who are working machines underground speak well of the ore they are opening on the lower levels.

The Mountain Top, though in good ore when shut-down in July, had insufficient funds to construct a tram and mill, as well as develop, and G. H. Barnhart thought it best not to work at a high cost during the winter. It is rumored that the Liberty Bell people, who lost the Humboldt to the Smuggler-Union company, have been considering the purchase of the Mountain Top.

The condition of the Atlas is doubtful; but excellent work is being done with flotation there.

The Wanakah company (which has the Bright Diamond, Ironclad, Memphis group just north of Ouray), the American Nettie mill, and the pyrite smelter are in something of a mix-up. The Roberts family of Buffalo are now practically out of it. They had a splendid chance, but no managerial ability, and an excess of nepotism. It was too much of a family affair. They increased the capacity of the smelter at an absurd cost, and without regard to a continuous supply of ore. Barnhart is now general manager. He put through the original deal some six years ago, and then was forced out to make room for John T. Roberts, Jr. Beebe, water commissioner of Syracuse, New York, an engineer who made money at Cobalt, is now president and financier of the company. He is also interested in the Mountain Top. The American Nettie people (Wrisberg and Hartman of St. Louis) are developing their holdings by an adit below the lower quartzite, and are said to be in good ore.

Forester is going to make good on his lease on the National Belle at Red mountain, one of the old properties belonging to George Crawford group, and in the early days a good producer. There is not the slightest doubt that a small syndicate with a capital of $25,000 or $50,000 could go into that district, Red mountain, and make good by taking bonds and leases on half a dozen properties, and putting up a small custom mill with crusher, tube-mill, a couple of tables and flotation, but there was never much home money available for Colorado mines.

TORONTO, ONTARIO

Dome Mine.—Boston Creek Gold Prospects.—Nickel.—Fond du Lac.—Sesikinika.

At the Dome a station has been cut on the 700-ft. level, but little work is being done at this depth until improved haulage equipment has been installed on the 500 and 600-ft. levels. When this is finished, and the tank capacity in the mill increased, it is anticipated that the quantity treated can be increased to 45,000 tons per month. The output in September was 28,500 tons averaging $4.87 per ton.

There is great activity in development in the Boston Creek gold district, about 53 miles north of Cobalt. Prospectors have staked a number of claims there, and in the surrounding country, including most of the townships of Boston, Pacaud, and McElroy.——John Papapassimakes controls a large area, the most important claim being the Kenzie, where a large force has been at work all the season. The vein which has been stripped for 450 ft. has a 12-in. pay-streak, rich in free gold, the value increasing with depth. Two shafts are down 28 and 30 ft.——The Dominion Reduction Co. has optioned adjoining claims, has erected plant, and is sinking to 200 ft. on the ore-body 10 to 15 ft. wide, in some places low-grade.——The Sherwin-Williams Paint Co. owns a property, and is sinking two shafts on a promising 7-ft. vein.——Other mining men interested in the camp are James Hughes of Haileybury, C. Foster of the Tough-Oakes, S. Dobre, and C. S. Gzowski of Toronto, and T. Flynn. New discoveries are reported daily.

The Ontario Nickel Commission has completed its investigations in the Sudbury nickel district, where the companies interested afforded them every facility for familiarizing themselves with the conditions of the industry, including an inspection of their books and records. They will probably visit other mines in the north of Ontario, and will afterwards go to the United States for information concerning the refineries. They may also visit the island of New Caledonia, about four days from Sydney, New South Wales. It will be several months before any report can be made.

The British firm of Vickers & Maxim has sent an expedition into the Fond du Lac country, east of Lake Athabasca in northern Alberta, to investigate the nickel deposits understood to occur in that region. The party, consisting of 25 engineers and a large number of assistants and laborers, is in charge of H. V. Dardier, who went to England some time ago with specimens from Fond du Lac, in order to interest capitalists in the district. The expedition left Edmonton about three weeks ago, and as every effort was made to keep its object a secret, little was known of it until it was well on its way. The explorers will remain in the country for over two years, and took with them $50,000 of machinery and $10,000 of supplies. The total cost will be about $100,000.

The Bilsky syndicate of Montreal and New York capitalists have taken over the Smith-Labine gold claims at Sesikinika lake, comprising 120 acres, on which 18 veins carrying free gold have been discovered. A. M. Bilsky is in charge, and will employ 100 men at trenching.

PETROGRAD, RUSSIA

Final Statistics and Information on Gold and Platinum Dredging in Russia During 1913.—Possibilities of the Amur Gold Region, Siberia.

As usual the Permanent Consulting Board of Gold and Platinum Producers in Russia has collected data obtained in response to question-sheets sent out to the various gold-producing districts of the country, including Siberia, in which dredges are used. The present report, as can easily be understood, has been greatly delayed—it is for 1913—on account of the disturbance to the social organism caused by the War. The number of firms that have responded to the call for details is 16; these among them controlled 55 dredges: thus the report deals with three dredges more than did the report for 1912. But the report, as usual, is not complete. Full details are given for only 48 dredges—an increase of six compared with 1912, showing that the attentions of the Consulting Board are becoming more appreciated.

The companies that have supplied details are: The Bogoslovsk Gold Co., the Borovin Gold Co., the Verch-Isset Mining Co., the Zauralsk Mining Co., the Novo-Udylsk Gold Co., the Olekminsk Gold Co., the Putiloff Factories, A. A. Sovvinik successors, the Teptyarsk Gold Co., the Central Siberian, and Y. K. Yuskoff.

The total gold and platinum in 1913 for 48 dredges of which complete details were received was 110,348 oz. The general efficiency per dredge is expressed in the gold and platinum produced in the different years, 2298 oz. per dredge in the year 1913 against 2096 oz. in 1912; 2021 oz. in 1911; 1792 oz. in 1910; and 1811 oz. in 1909. But an increase per unit of dredge in gold and platinum production does not necessarily mean that the operations have been more efficiently conducted. The increase is largely due to the use of better and larger dredges. Yet the workmen naturally acquire more skill in operating, and probably also a more enthusiastic interest in the work. Thus though the production per dredge in 1913 was well in excess of that of 1912, the number of hours worked was appreciably less, being 3302 in 1913 against 3437 in 1912, which, of course, indicates a more efficient organization.

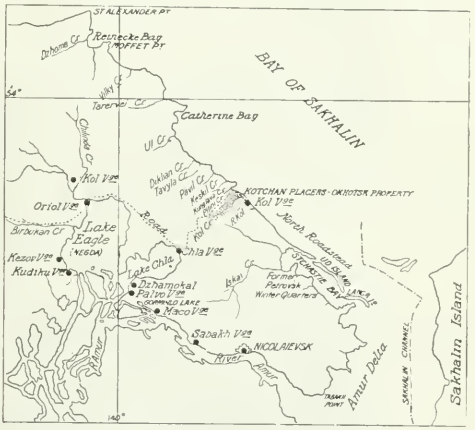
The quantity of gravel raised per dredge in 1913 was 247,687 cubic yards against 213,438 cu. yd. in 1912. The total production of gold and platinum by dredges in 1913 was larger in 1912 by 26,333 oz., an advance of 19.8%. This, in view of the fact that complaints are common respecting stagnation in the gold industry of the country, and the difficulty of stimulating to a larger production, shows that the Russian gold-producer, whether on his own initiative or under the pressure of Western European partners, is tending to employ large-scale methods of production that experience has proved worth-while, particularly as lack of success in the past has been ascribed to the petty methods employed.

Capacity of the dredges: four dredges produced up to 527 oz. of gold and platinum; two from 527 oz. to 790 oz.; three from 790 oz. to 1053 oz.; nine from 1053 oz. to 1317 oz.; six from 1580 oz. to 1843 oz.; seven from 1843 oz. to 2107 oz.; three from 2107 oz. to 2370 oz.; four from 2370 oz. to 2633 oz.; six from 2633 oz. to 2897 oz.; two from 2897 oz. to 3160 oz.; and two from 3160 oz. to 3423 oz. Eight dredges produced respectively quantities exceeding 3423 oz. rising to over 5260 oz. over 8952 oz. and over 1000 oz. for the three last in the series.

One point in which the report fails as compared with previous ones is the absence in the column headed 'Observations' of the names of the various dredge-makers. It is unfortunate that this was omitted, as it furnished a clue to the disposition of the gold-producers and enabled one to estimate the influence of the Russian dredge-makers, such as the Putiloff and the Neviansk companies, the former of which was known to be governed by outside influences, so much so as to discount the claim to Russian nationality.

Gold mining in the central far-eastern area, particularly in the Amur territory, is at present the subject of considerable interest. The old question has been raised of ways of communication in the districts where the gold deposits exist. In the Zei district, including seven mining areas—the Zei, Aldan, Timpton, Unyin, Sugdzhar, Gilyuisk, and Mogotsky—which embrace an area of 200,000 square versts (1 verst = $\frac{2}{3}$ mile) with an annual production of 400 poods (about 210,000 oz.) of gold, transport has always been difficult. Notwithstanding the energetic measures of the regional authorities and of the companies who joined them to have new roads made, and the old ones improved in the Zei district, only two roads are now available; these are only 156 miles long.

On account of the lack of roads in the gold-mining districts, a number of them have not been exploited properly. This refers more to the outlying districts; for example, in the areas of the rivers Aldan, Timpton, and Unyin, and others, there is a large number of properties containing rich gravel that are not being exploited because of the impossibility of delivering supplies, etc. Where there are wagon-roads, such as at Zei and Mogot, etc., it has been found profitable to exploit areas with



PART OF THE AMUR REGION, SIBERIA.

half the content of gold in the above-mentioned areas. Wages are 5 rubles ($2.50) per day with keep, while in the districts away from the roads the wage never exceeds $1.25.

The question of a part permission to engage Koreans and Chinese workmen at the mines, with less formality respecting passports, and their verification, is being discussed. Zeyu-Pristan, the centre of the Amur gold industry, was visited by the Priamur Governor-General Gondatti, and he decided to construct some wheel-roads in the gold-mining regions. For this purpose he was granted a credit of $1,500,000. Besides this, by his instructions, work on the main road between Zei and Tygda has been started, and the cost to be allowed is $132,500. Among other things, the Amur companies called the attention of the Governor-General to the fact that recently there has been observed an export of gold abroad without the certificate of the Russian authorities. On this account a special council of the companies was called and they decided to apply for the publication in legal form of the special prohibitory paragraphs in the mining law, in virtue of which workmen and employees on the mine have no right to keep gold, and are obliged to deliver it to the mine offices where it has to be entered in a special register.

The question has been raised concerning gold dredging along the rivers of the Amur basin. It is considered that dredging in this area has good possibilities. Peasants in the Priamur district have for years made good profits by washing the river sands.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

It is probable that the Kensington mine will be re-opened next spring, and a 500-ton mill erected, according to D. C. Jackling of the Alaska Gastineau company.

At Treadwell the Mexican shaft is to be enlarged and deepened to five compartments and 400 ft. below the present bottom at 1700 ft. Cross-cuts will be driven at 1750 and 2100 ft. to a point under the shaft, connections to be made by raising. A new hoist and head-frame are part of the improvements.

Two miles south of the Treadwell properties is the Nevada Creek mine, in charge of M. S. Hudson. Twelve men are working, but more are to be engaged. A long adit has been driven. A 20-stamp mill is ready for ore. The company has been reorganized.

According to J. H. Mackenzie an 8000-ton mill has been designed for the Alaska-Juneau company. It will consist of four No. 9 gyratory-crushers, two jaw-crushers, twelve 6 by 8-ft. ball-mills twelve 7 by 10-ft. tube-mills, 48 roughing-tables, and 120 finishing tables. The plant will be in four units of 2000 tons each, the first of which is to be at work at the beginning of 1917. In the power-plant, to be on the beach, will be two 5000-kw. turbo-generators. Grading is to be commenced at once.

ARIZONA

COCHISE COUNTY

At the Sacramento shaft of the Copper Queen 30 ft. of concreting has been done, starting below the 1700-ft. level. Work was also commenced at 1200 ft. Hoisting of ore is not hindered.

A considerable amount of construction is under way at the Junction shaft of the Calumet & Arizona. A seventh hole is being drilled on the Washington and Angel claims, near the C. & A. hospital.

The Shattuck-Arizona company is mining 350 tons of 6% copper, 100 tons of gold-silver-copper, and 50 tons of lead ores per day.

The Bisbee Copper Mining & Development Co. is selling shares at Bisbee. Three drill-holes are to be put down in what is considered promising ground.

Developments in the Commonwealth Extension at Pearce are good. Some ore has been shipped.

The Mascot is sending copper ore to El Paso. The mine, in charge of J. W. Prout, is opening splendidly. In the Palace of Mines at the Exposition at San Francisco, is a large piece of ore from this mine.

GILA COUNTY

Asbestos has been found 12 miles from Globe, and claims have been located by Fay and Hubbard.

During September the Iron Cap mine produced 14 cars of ore assaying 12.65% copper and 11.7 oz. silver. The profit was $18,624.

At the Inspiration mill, when four Marcy mills are installed, the crushing departments of nine units will be complete. Three 100-ft. and one 200-ft. diameter Dorr thickeners are to be constructed at the bottom terrace of the mill-site. These are to make a thick residue prior to its going to Ellison canyon, and also to save the clear water for re-use. The mine is worked six days per week. Both main shafts are ready for operation, construction being complete.

GREENLEE COUNTY

The strike situation at Clifton last week was as follows:

A large number of pickets were placed at the mines and works on October 20, the strikers fearing that the companies were trying to bring in strike-breakers during the conferences.

A petition is being circulated for the recall of Governor Hunt.

On October 23 the conferences at El Paso ended without result, and nothing of moment has occurred since.

On the 25th the strikers gave R. S. Trejo, editor of *El Noticioso*, a Mexican paper at Morenci, 10 hours to leave the district, with threats of violence.

MOHAVE COUNTY

Seventy acres of the old Pioneer estate in the Oatman district has been acquired by Allan G. Burris, well known at Cripple Creek, Colorado. The main shaft is 400 ft. deep, and a 10-stamp mill is ready for crushing. Work has been started in charge of G. F. Moser. The company's name is the Oatman Pioneer Mines, Inc.

The United Eastern company is preparing to sink a three-compartment shaft, and grading for a 200-ton mill. An Allis-Chalmers hoist and Ingersoll-Rand compressor, drills, etc., have been ordered. On Silver creek a supply of 60,000 gal. of water per day has been developed. The supply will be augmented when the mine shaft is down 500 ft. At 465 ft. the vein is 350 ft. long, with wide shoots of high value. At 565 ft. the vein is also wide and valuable.

A dispute has arisen between the United Eastern and Tom Reed companies. The former connected its workings with the latter for ventilation and safety; the latter objected, and disobeyed the order of the State mine inspector, hence the trouble.

CALIFORNIA

Oil-production of the Kern River, McKittrick, Midway-Sunset, Lost Hills-Belridge, Coalinga, Lompoc-Santa Maria, Ventura County-Newhall, Los Angeles-Salt Lake, Whittier-Fullerton, and Summerland districts in September totaled 7,330,038 bbl., from 6109 wells. There were 140 wells drilling, and 31 completed during the month. The yield was a decrease of 3409 bbl. per day, compared with that of August. Shipments amounted to 7,778,807 bbl., also a decrease. Stocks decreased about 400,000 bbl. to 59,624,905 bbl.

According to James H. Tibbits, recently with the State Engineering Department, who was in Sacramento during the week on his return from a trip through Eldorado, Amador, and Calaveras counties, there is great activity in mining, and capital is offered freely for good properties.

CALAVERAS COUNTY

An old asbestos mine, six miles from Copperopolis, is being re-opened, and a plant for preparation of the product will be erected.

ELDORADO COUNTY

Gravel areas near Coloma, south fork of the American river, are being prospected with a Keystone drill. J. H. Mulloch of San Francisco is in control.

Around Placerville there is considerable mining activity at present.

NEVADA COUNTY

A 280-hp. water-power plant is being erected by the Artic Mining Co. in the Washington district. It will drive a compressor and other machinery.

The Black Bear company has ordered a duplex compressor of 1000-cu. ft. capacity, pipes, and a pump.

Near Moore's flat the Mohawk antimony mine is being opened by W. McLean of Nevada City and C. Scheunert of Sacramento.

Placer County

Near Colfax the old Big Oak mine is being unwatered by J. Toman, S. R. Break, Hubbel and others. On account of litigation it was idle for 21 years.

San Benito County

(Special Correspondence.)—A promising antimony prospect in the Lone Tree district is being developed by H. V. Underwood and L. H. Day. A good vein has been cut by an adit. Other mines in the same district that have been idle for years are being examined. Visitors are coming into the county to prospect, while capitalists are coming to buy, and it is hoped that many prospects will be developed in the near future. The county is rich in quicksilver, copper, and antimony, as well as many of the industrial materials.

Hollister, October 24.

Shasta County

The Red Top Mining Co. of Redding has bought the Black Cloud and Red Top properties for $13,000. A stamp-mill will be erected later.

deposit of chrome on Elk creek. It is approximately 800 ft. wide, on the surface, and has been traced for a length of 1200 feet.

Several hydraulic mines are being prepared for winter work. Among these are the Dave Huey, Sixes group, Classic, and Crumpton. The last is a practically virgin property containing 300 acres. George H. Crumpton is superintendent.

Happy Camp, October 18.

COLORADO

Clear Creek County

There is a shortage of teams at Georgetown to carry the ore mined by lessees at the Waldorf and other mines. The Terrible Dunderberg and Mendota mills are working full time.

Gilpin County

At Blackhawk a syndicate of local people has secured ground near Glacier lake, and will develop tungsten deposits. Rich shipments of gold-silver-copper ore continue from the Pittsburg mine on Russell gulch.——Lessees at the U. P. R. have cut good ore at 265 ft. depth.

DREDGE ON THE DERRY RANCH, COLORADO.

Sierra County

The Willoughby mine, 10 miles north and west of Sierra City, has been bonded by R. G. Moss of Berkeley. The property is being prepared for winter operations. An electric plant will be installed in the spring, also a compressor and two machine-drills. A steam hoist and pump are being installed at the Monitor mine near Downieville.

Siskiyou County

(Special Correspondence.)—Reeves Davis and associates of San Francisco are preparing for a busy season at the Van Brunt hydraulic mine. Approximately 2000 inches of water is available, and additional flumes are under construction. Henry C. Howard is superintendent.

San Francisco people are developing the Little Oak Hollow quartz mine on Elk creek, six miles from Happy Camp. A two-stamp mill has been erected, and it is proposed to soon have 10 stamps in operation. The ore is a free-milling quartz. M. Anderson is superintendent.

The Siskiyou Mining Co. is extending its 15-mile flume 1½ miles to work the gravel deposits on the Muck-a-Muck flats. The deposits have been thoroughly prospected and show good gold-content.

Schuler and Dolittle are developing a recently discovered

Lake County (Leadville)

(Special Correspondence.)—The new 6-cu. ft. dredge at Derry ranch, mention of which was made in the Press of August 14, is working an average of 21 hours per day, everything going smoothly. The first clean-up, for the week ended October 16, yielded nearly $7000. On account of the high cost of power, (1.65c. per kw.-hour) and labor, expenses are rather high, but the results are good. The boat, which was designed and equipped by the New York Engineering Co. of New York, cost about $125,000.

Leadville, October 19.

A new 300-hp. hoist was started last week at the Garbutt, which is producing 200 tons of ore daily. A mill is contemplated for this mine.

The Fortune mine is to send carbonate ore to the Zinc Oxide plant.

Rich gold ore is again being opened in the Connors lease of the Ibex.

Summit County

Molybdenite has been discovered near Fremont pass. From the Molybdenite mine, which has been leased to Leadville men, 1000 tons was recently treated at the Leadville District

mill, details of which should soon be made public. The ore contains up to 2% molybdenum.

TELLER COUNTY (CRIPPLE CREEK)

From the vein cut at 850 ft. in the Jerry Johnson, the Cripple Creek Deep Leasing Co. is shipping ore, the greatest depth ore has been mined at Ironclad hill. This company leases below a depth of 650 ft.; the ground above is leased by F. Caley, who is operating a 50-ton mill.

The Moose mine, on Raven hill, is being examined by T. Kavanaugh, well known at Cripple Creek. No work has been done since 1904. The property yielded some rich ore and paid dividends. The main shaft is down 1050 ft. on the incline.

Lessees at the C. K. & N. mine on Beacon hill are shipping at the rate of 550 tons per month. Development is encouraging. The output to date is $1,350,000.

IDAHO

BLAINE COUNTY

The Wilbert Mining Co., operating in the Dome district, has declared its first dividend of 1c. per share, equal to $10,000. Assessments amounting to $65,000 have been paid. The new 100-ton mill is producing high-grade lead-silver concentrate.

SHOSHONE COUNTY (COUER D'ALENE)

According to figures prepared by A. W. Belden and G. T. Edmiston of Wallace there are 5000 men working at mines and mills of this region. In the Wallace district the following are employed:

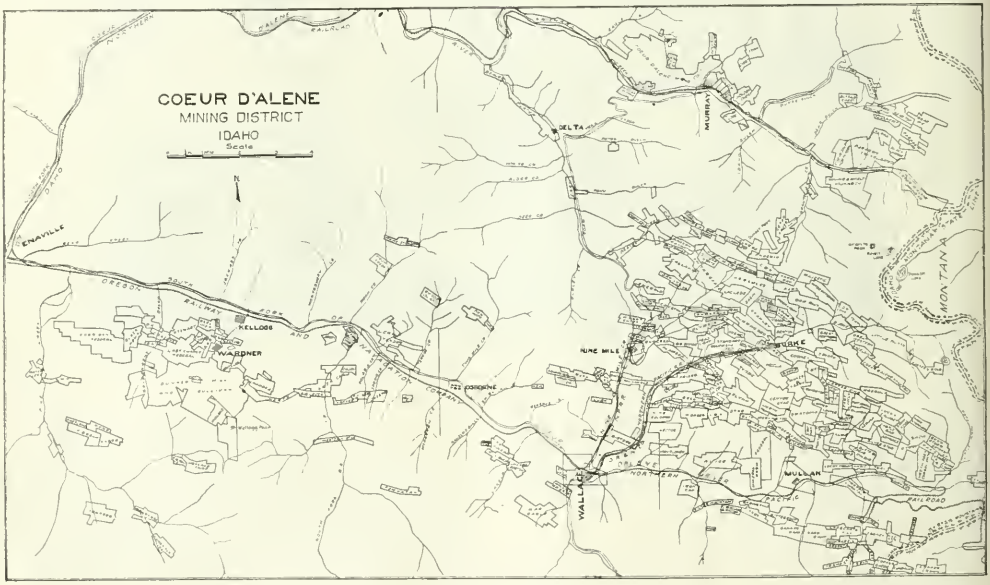
Bunker Hill and Sullivan, Wardner 800; Last Chance, Wardner 200; Caledonia, Wardner 40; Stewart, Wardner 250; Hercules, Burke 400; Standard, Mace 350; Hecla, Burke 250; Morning, Mullan 350; Hunter, Mullan 200; National Copper, Mullan 40; Interstate-Callahan, Nine Mile 200; Tamarack, Nine Mile 200; Success, Nine Mile 200; Marsh, Burke 80; and Frisco, Gem 150. In addition to these there are a large number of mines employing from 5 to 20 men each in the following districts: Pine Creek, Hypotheek, Highland Surprise, Little Pittsburg, Nabob, and Antimony. At Murray, 20 miles from Wallace, are the Paragon, Terrible Edith, Jack Waite, and Crystal. At Sunset the Silver Moon and the Tuscumbia. Big Creek, five miles from Wallace, has the Yankee Boy, G. Scott Anderson lease, Polaris, and Nellie. Placer Creek includes the Livingston Bros. holdings. Tributary to Burke, among the mines employing small crews and with ore opened are the Sonora, Oom Paul, Aetna, Imperial, and Veteran. In the vicinity of the Idaho-Montana summit, east of Mullan are the Silver Cable, Carbonate Hill, Reindeer Queen, and Snowshoe. The Saltese copper belt has the Richmond, St. Lawrence, Monitor, and Copper Age.

At the present rate of production the Interstate-Callahan mine has four years' supply of ore for the mill and shipments. The monthly output of concentrate is 6000 tons. In the suit of the company and the Callahan Mining Co., Judge Deitrich decided that further proceedings in the State courts be stopped.

September profits of the Stewart were between $65,000 and $70,000.

The Keystone Mines Corporation, operating on Blacktail mountain, in the Pend Orielle Lake region has 30 men on development, erected modern machinery, and blocked out a large quantity of copper-gold-silver and lead-silver ores, and is soon commencing shipments of these ores to Tacoma and East Helena respectively. Volney D. Williamson is in charge.

The Riblet Tramway Co. of Spokane has secured the contract to construct an aerial tram from the Hypotheek mine to the mill, which is to be built as soon as development warrants it.



CLAIM MAP OF THE COEUR D'ALENE, IDAHO.

The new aerial tram of the Interstate-Callahan is working well. At the Gertie the cross-cut is in 3720 ft., and the vein should be cut within 100 ft. This distance was driven in exactly a year, at a cost of $67,000.

At the Constitution zinc-lead mine on Pine creek, a compressor and hoist are to be installed; later on a mill of 150-ton capacity. A. G. Kerns of Wallace is president of the company.

The Cooney properties in the Burke district, have been bonded to M. W. Neary of Spokane for $150,000, $25,000 having been paid to Mark Cooney last week. Development will commence at once.

The Federal Mining & Smelting Co. is being sued by N. A. Butler for $10,000, for injuries received in its mine.

MICHIGAN

THE COPPER COUNTRY

The Calumet & Hecla re-grinding plant produced copper in September at the rate of 4,000,000 lb. per year, at a cost of 4c. per pound. The company is erecting a purifying plant adjacent to the electrolytic plant to improve the acid used in the latter.

The Franklin mill is operating four stamps, and the mine is producing from 800 to 1000 tons of ore daily. More machines are to be started on the conglomerate lode, the present quota being 34, and four on the amygdaloid. The cross-cut to the Kearsarge lode is out 3500 ft.; it should reach there at the end of the year.

A turbo-generator is being installed at the Champion mill, a duplicate of that which has been working at the Baltic for two years. Exhaust steam from the stamps is to drive the new engine. Ore containing 50 lb. copper per ton is coming from one of the Champion shafts.

At the South Lake mine a new steel rock-house is being erected.

The drilling scheme at the White Pine Extension consisted of holes, spaced 1000 ft. apart, so situated as to cut the copper material at a depth of approximately 400 ft. from the surface on their inclination; a second line of holes, spaced 1000 ft. apart, to cut the ore at 800 ft., and a third and final line of holes, 1000 ft. apart, to cut the ore at 1200 ft. The second line was placed half way between the holes of the first and third lines and were 250 ft. from the second line, according to Homer A. Guck.

So far, the line of 400 and 800-ft. deep holes has been completed for a distance of 15,000 ft. along the strike. In all of these none failed to find commercial ore. The first hole on the 1200-ft. deep line is completed. This shows similar formation and value, but is ⅓ wider. Drilling will be completed when the remaining 1200 ft. holes are finished. At present there are four drills working two shifts each on these deep holes. There are six drills altogether working on the property. Including the time lost in moving, the drills made about 50 ft. each per day of 24 hours. Drilling has shown the copper to be largely confined to two shale-beds that are separated by a six-foot stratum of sandstone, which is copper-bearing, but not so rich as the adjoining shale. The lower shale is the richer of the two. Drill samples of both the sludge and core show this vein to contain from 30 to 70 lb. of copper per ton. The width varies from 5 to 7 ft. The upper shale is not so uniform as the lower either in width or copper content. It varies in width from 7 to 15 ft., and in copper from 17 to 30 lb. A probable average mining width of the combined veins, which can be extracted from one drift not removing the included sandstone, will be 13 ft., and the average refined recovery based on an 80% mineral, will be 24 lb. The dip of the shale beds at the east end of the property is 85° to the vertical, flattening to a dip of 83° at a depth of 1200 ft. as shown in the first deep hole. At the west end of the property the dip at the surface is 78°, flattening slightly in depth as shown in the 800-ft. drill holes. Within 60 days drilling will be completed. Active mining operations will then start with the sinking of a large four-compartment shaft, the situation of which has already been decided on.

MISSOURI

JASPER COUNTY

Prices for concentrates were a little lower during the week ended October 16. The output of the Missouri-Kansas-Oklahoma region was 6229 tons blende, 282 tons calamine, and 827 tons lead, averaging $80.04, $50.16, and $49.16 per ton respectively. The total value was $554,117, and for 42 weeks, $18,927,053.

On account of the value of the sludge made in the mills, all of the new plants are being provided with extensive sludge departments.

A new 300-ton mill at Belville has started on tailing from the old Standard Hill mine. The plant can treat either tailing or run-of-mine ore.

MONTANA

FERGUS COUNTY

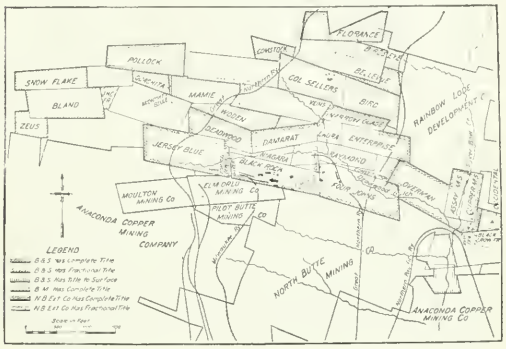
Litigation between the Barnes-King and Kendall companies has been settled by the former purchasing the latter's property for $100,000, $40,000 cash, and $10,000 per month for six months. A 400-hp. water power-plant is included, the Barnes-King for years paying $7200 per year for power supplied. The output of the Barnes-King properties will now increase.

MADISON COUNTY

A fair amount of development is under way in the Twin Bridges district, and a feeling of optimism prevails. Butte people are said to be investigating some properties.

SILVERBOW COUNTY

The Clark-Montana Realty Co.-Elm Orlu Mining Co. *v.* Butte & Superior Copper Co. suit commenced at Butte on October



PART OF BUTTE, SHOWING ELM ORLU AND BUTTE & SUPERIOR CLAIMS.

18, before Judge G. M. Bourquoin of the Federal court. It is a very important case, and a large number of famous mining men are retained by both sides. A large map of the properties is part of the evidence. The plaintiff alleges that the apex of the Rainbow lode is within its Elm Orlu claim, and that the lode passes through the Black Rock claim of the Butte & Superior. Damages are asked.

The accident at the North Butte mine last week, whereby 16 men were killed and six injured, by an explosion of powder at the surface, will not interfere with ore production, which is 1400 tons per day. The company, under a clause of the Montana compensation law, insures its own employees, and will pay the dependents of the men killed and injured as soon as possible. The cause of the explosion will remain a mystery.

NEVADA

ESMERALDA COUNTY

At 930 ft. in the Jumbo Extension the east drift shows 6 ft. of $100 ore, which is being extracted. Two new stopes have been started on the contact segment of the Jumbo Extension orebody at 918 ft. depth. Seven feet of $20 to $25 ore is being broken.

In a raise above the 100-ft. level, the New Goldfield Simmerone company has opened 4 ft. of ore assaying $525 per ton. Lessees extracted some rich ore from above this point two years ago.

At 600 ft. in the Silver Pick the east cross-cut has passed through 18 ft. of formation of low value.

At the Spearhead property two shifts are employed in unwatering the old Shale shaft, 250 ft. deep. It is to be sunk to 950 ft. to the latite-shale contact. An air-compressor and drills are to be used.

At Pioneer, the Pioneer Consolidated is employing 16 men, with more to be added. Development is satisfactory, and the mill is working well.

Humboldt County

Copper deposits are said to be numerous in this county, but undeveloped. Salt Lake people have acquired 10 claims in the Red Butte district, 15 miles north of Antelope on the Western Pacific line. Prospects are considered good.

The results of reconnaissance work in Nevada by F. L. Ransome have been published by the U. S. Geological Survey as Bulletin 414, 'Notes on Some Mining Districts in Humboldt County, Nevada.' The bulletin embodies the results of an examination of some 7000 sq. miles, including the Seven Troughs, Rosebud, Star, Unionville, Humboldt, Fitting, Chafey, Kennedy, Adelaide, Red Butte, and Coppereid districts. Some of the districts examined, such as Seven Troughs, Rosebud, and Red Butte, have been prospected only within the last decade; others, like Star City and Unionville, reached their height of productiveness in the sixties, and have not yet participated in the recent general revival of mining activity in Nevada; one or two, like Chafey, have received new names and have been exploited in various ways; still others, like Adelaide, have been intermittently active for over 35 years, oscillating between prosperity and decay. Mr. Ransome discusses the mineralogy, geology, and mining operations of the region. His conclusion is that the southern portion of Humboldt county is part of a metallogenetic province, characterized chiefly by the prevalence of antimonial ores of silver with numerous and widely scattered deposits of stibnite and cinnabar. There are in addition some deposits of gold-silver, copper, and nickel-cobalt ores. Ore deposition probably began immediately after the intrusion of the Triassic and Jurassic sediments in late Mesozoic time, by a granitic igneous rock of the same kind as that which invaded the sedimentary rocks of the Sierra Nevada at the same period and continued into the Tertiary. The known Tertiary deposits are essentially gold-silver ores and copper ores, but it is possible that some of the other types are also Tertiary.

Lyon County

Between the 100 and 200-ft. levels of the Ludwig mine of the Nevada-Douglas company, a shoot of oxide ore containing 23% copper, 7% iron, and 4.5% lime, has been cut in the limestone foot-wall. It is probably an extension of the orebody opened at 40 ft. depth.

Mineral County

(Special Correspondence.)—Copper men are sure that the present situation of the metal will mean the making of the Santa Fe district. Developments during the past few months have resulted in great optimism.

The Calavada Mining Co. has completed the cutting of a station at 1000 ft. and is now cross-cutting to the vein. This property is controlled by the Giroux interests, who will sink to water, which is expected at about 1200 feet.

Arrangements are completed for the financing of the Luning-Idaho Mining Co., and work will be started on a large scale early in November. This property lies in the belt containing the Fermina holdings, now being extensively leased; the Calavada or Giroux property, and the Duffy mines recently purchased from J. N. Bealer and associates.

Lessees in the New York Canyon area are shipping over 40 tons daily. All of this ore is considered high grade, as it must assay over 6% to pay the hauling to railroad, freight, and smelting charges, and it fairly illustrates the great possibilities of this district, when the large tonnage of low-grade ore that is left on these dumps for future times is considered.

The Nevada Gold Mines Co., Ltd., which is operating on an extensive plan, south-west of town, is opening high grade gold-silver ore. Steady production will be made this fall.

R. B. Todd has arranged with eastern people for the formation of a company to take over the Luning Gold Mines Co., and work will commence in the near future. This property has been a good producer, and has a large tonnage of milling ore blocked out.

Development at the Alameda Mines Co.'s ground is going on steadily. It is rumored that a leaching-plant will be erected there before long.

There are 20 sets of lessees working copper properties at a profit here, shipping, in most instances, ore around 5 to 10%. This ore will eventually be shipped to the leaching plant at the Nevada-Douglas at Ludwig.

Luning, October 14.

Nye County

The plan for consolidation of the principal producing properties on Litigation hill, with the Manhattan Milling & Ore Co.'s plant to be included in the merger, so that as soon as operation is started the new company will be able to treat ores in its own mill, and thus do away with the high custom mill rates, is well under way. A meeting of the owners in the mining companies interested, with Mushett and Wittenberg, who own an interest in the mill, was recently held at Tonopah, and a tentative agreement was reached between those concerned.

Kane and Whitman, lessees at the Union No. 4 claim of the Dexter-Union company, are developing a large quartz body at 150 ft. depth.

The Big Pine mill continues to treat 150 tons of ore per day, with 40c. residue. The crusher-plant receives 450 tons, but rejects 300 tons, leaving 150 tons for the tube-mill and amalgamating plant.

The Sunset Mining & Development Co. at Rhyolite is adding a Hardinge ball-mill, Dorr duplex classifier, and other equipment to its plant. The present daily capacity of 50 tons is to be doubled. From $4 to $10 ore the recovery is 90%. Developments are encouraging. The main adit is in 2200 ft., but has 800 ft. to go to reach the Denver vein.

Tonopah mines last week produced 9704 tons of ore worth $200,632. Bullion shipments were 98,112 oz. from the Belmont, 97,055 oz. from the Extension, and $56,350 from the Tonopah Mining.

The West End mill treated 1035 tons, 275 tons of which was from lessees, etc.

Since May 21 lessees at the Montana and Midway mines have produced a total of 3615 tons of ore, the week ended October 14 totaling 440 tons. This was treated at the West End mill. Two 50-ton cars were also sent to the Belmont mill at Millers. Average royalty is 22.5%. After deducting treatment the yield is $23 per ton, equal to a total of $89,000, of which the tributers received $67,300.

OKLAHOMA

Ottawa County

North of Commerce the Cornfield Lead & Zinc Co. has been drilling, and the holes have shown the richest ore in the region. Assays were as follows:

Depth, feet.	Zinc content, per cent.
210 to 213	19.33
213 to 215	15.83
215 to 217	24.65
217 to 219	22.00
219 to 221	38.33
221 to 223	61.66
223 to 225	38.37
225 to 228	7.80

UTAH

Emery County

Salt Lake City people have contracted to purchase not less than 100 carloads of manganese ore from deposits near Greenriver.

Beaver County

Little has been heard of the Fortuna district lately, but high-grade gold ore is being extracted from the Davis lease of the

Lumley and Moore ground, which is reported to have been sold to the U. S. S. R. & M. Co. There is a good road into the district.

Juab County

Ore shipments from Tintic last week totaled 121 cars from 13 properties. According to H. Wisener Hammond, who recently inspected the district, the future of the place depends on deep development, from which a number of the smaller companies should be consolidated. To supply the new motors at the Chief Consolidated and Eagle and Blue Bell mines the Utah Power & Light Co. is erecting a sub-station.

Piute County

On October 19 the Mineral Products Co.'s potash plant commenced work at Marysvale. The first shipment will be 93% concentrated sulphate of potash, packed in cotton bags. The daily output of the unit will be up to 30 tons. Higher-grade material is expected later on.

Summit County

Ore shipments from Park City last week totaled 1920 tons, as follows: Daly-Judge, 652; Daly West, 221; Silver King Coalition, 740; and Silver King Consolidated, 307 tons.

According to the *Deseret Evening News*, the treatment capacity of the State has been increased by 3000 tons per day since the beginning of the year. The new mills, their location, and daily capacity in tons, are as follows:

Broadwater, Park City	500
Big Four, Atkinson	300
Tintic, Silver City	300
Utah Leasing, Newhouse	300
Caldo Mining, Frisco	200
Park City mills, Park City	200

The following increases to capacity have been made:

Silver King Coalition, Park City	100
Utah Apex, Bingham	225
Daly Judge, Park City	50
United States, Midvale	290

WASHINGTON

Ferry County

(Special Correspondence.)—The West Virginia Mining Co., having purchased the property of the Republic Consolidated Mines (the Lone Pine, Pearl, and Surprise claims), after paying down several thousand dollars, has failed to make one installment, has forfeited its rights to the latter company, and has gone out of business. One or two of the shareholders, however, are interested in the Republic Consolidated. With this deal some machinery that was purchased by the West Virginia company has been taken over by the Republic company and removed to the Surprise mine, where it is now being erected. A. B. Willard, who is largely interested in the last-named company, has become the head of the concern, and promises prompt payment for labor and supplies. He was a fortunate investor in the Interstate-Callahan company, of Idaho. The Lone Pine-Pearl-Surprise group has proved to be a meritorious property, and, if it is well managed, should be profitable.

Z. E. Merrill & Co., lessees of the Tom Thumb group, have been shipping ore from that property, and met its first pay-day from the returns.

The foregoing is all the news from Republic, excepting operations at the Ben Hur mine, now controlled by the British Columbia Copper Co., and the Knob Hill, from which nothing authentic can be learned at present.

The 150-ton smelter formerly owned by the Keller and Indiana Consolidated Co., at Keller, is reported as sold to the Spokane Metals Co. for $50,000, to be operated as soon as repairs can be made on a water-flume which supplies the power. The Keller smelter is fully equipped with a mill, two furnaces, and modern electric machinery. The plant was built several years ago by the K. & I. C. Co., at a cost of over $100,000, but has been idle nearly ever since for want of transportation.

A rich antimony prospect at Whitestone, discovered seven years ago by W. H. Ingham and a Mr. Whitcher, is reported to have been sold for a large sum to Eastern people.

Republic, October 15.

WISCONSIN

Iowa County

(Special Correspondence.)—At Highland the Saxe-Pollard company, of Milwaukee has purchased the complete surface equipment of the Milwaukee-Highland Mining Co., valued at $20,000. An option has been taken on the Lampe-Imhoff estate, and mining operations have been started.——W. B. Seaver of Chicago is negotiating for the purchase of the holdings of the St. Anthony Mining Co., including its plant, 400 acres of land valuable for farming as well as for mining. ——Large shoots of zinc carbonate ore have been cut in drilling by the New Jersey Zinc Co., over a distance of ¾ mile. This concern has been buying extensive areas of land.

At Linden two new power and concentrating plants are being erected, one for the Saxe company, the other at the Gilman mine; a third will be built for the Optimo Mining Co. of Indianapolis.——Drills at the Gilman mine have passed through solid sheet-formations 16 to 18 in. thick. On the Rolling lease the Optimo company's drills cut 12 ft. of milling ore. A score of new producers have been developed in this district during the year.

At Mineral Point the acid department of the New Jersey Zinc Co. is being overhauled after a 4 years' shut-down, caused by damage suits. The re-constructed unit will be ready for work on November 15, and will need 150 men. The output will be one 25-ton tank-car of commercial sulphuric acid daily. Large shipments of low-grade blende and carbonate ores are arriving from western states to be converted into zinc oxide.

Eight active producers are operating steadily in the Mifflin district.——The two Coker mines, owned by the New Jersey Zinc Co., equipped with twin separating plants, are producing from 6 to 10 cars of 45% zinc concentrate per week. The ore is delivered to the separating hearths of the company at Mineral Point, the residue going to the smelter at DePue, Illinois.

Milwaukee people purpose to establish an independent smelter somewhere near St. Louis, the ore supply to come from the Wisconsin region. Already 10 zinc mines have been purchased, and deals are on for several more.

Highland, October 20.

Lafayette County

(Special Correspondence.)—At Benton the largest producing district of the Wisconsin region, the regular weekly shipments amount to 40 cars of zinc concentrate of all grades. The leading producing mines are the Frontier, Calvert, Bull Moose, and Hird of the Frontier Mining Co.; Fox and Penna-Benton, of the New Jersey Zinc Co.; Crawhall and Thompson of the Field's Mining & Milling Co.; Kittoe, Wilkinson, Martin of the Vinegar Hill Zinc Co.; and Champion of the Wisconsin Zinc Co., and Indian Mound mine. A dozen new producers will commence before the end of the year, the Wisconsin Zinc Co. controlling three of them.

The Benton Roaster Co. (Utt-Thorne Mining Co.), completed a new ore separating-plant on the first of October, costing $20,000. Besides working on ore from affiliated mines, an outlet is offered to low-grade, independent producers.

The Field's Mining and Milling Co. started a new calcining and separating-plant on the Crawhall mine.

Four miles of hard macadam road is being built by the operating concerns at New Diggings to connect with the railroad, at this station, affording an outlet at all times of the year. At New Diggings the Wisconsin Zinc Co. will have in commission on November 20 the finest type of separating-plant ever erected here, costing $75,000. Ten Dings and Cleveland-Knowles separators will be employed. The plant will handle 150 tons of raw ore every 24 hours, and will be able to make 500 tons of top-grade zinc concentrate. Thirty drill-holes on the Blackstone lease held by the Vinegar Hill Co. have cut

zinc ore. A new shaft is being sunk and a plant is contemplated.

At Shullsburg the ore from the Winskill and East End mines goes to the new Wisconsin Zinc Co.'s roasters just started at Galena, Illinois. More attention is being given to the recovery of slime, the Overstrom, Wilfley, and Deister tables being preferred.——The Milwaukee-Shullsburg mine is treating tailing.

Benton, October 20.

WYOMING

BIGHORN COUNTY

The Ohio Oil Co., a subsidiary of the Standard Oil Co., has brought in a great well at Byron, producing 140,000,000 cu. ft. of gas per day. This concern has been drilling on some land of the Utah-Wyoming Consolidated Co., and has two wells down to 1500 and 1715 ft. depth.

CANADA

BRITISH COLUMBIA

According to A. W. McCune of Salt Lake City, the lack of a market for the zinc output of the properties now operating in this province has done more to retard the industry than anything else, and it has prevented development of a number of promising prospects. The improvement in methods of treating zinc ores, together with the financial aid the Canadian government is rendering in establishing zinc smelters, promises to result in great activity.

MEXICO

CHIHUAHUA

According to C. L. Baker, legal representative of the American Smelting & Refining Co., at El Paso, Texas, the Chihuahua smelter has been confiscated by Villa, who is about to operate it. There are 2000 tons of fuel at the plant.

SINALOA

On October 26 the steamer *Grace Dollar* arrived at San Francisco, California, with Frank Perry, manager of the Lluiva de Oro Mining Co., and bullion worth $100,000. Bandits attacked a mule-train carrying the metal on September 20, but were routed by the advance guard.

SONORA

Unless the Naco or Nogales branch of the Southern Pacific railway is soon opened Cananea will be closed down again.

MAP OF MEXICO PREPARED BY THE NEW YORK WORLD, SHOWING THE AREAS CLAIMED BY THE SEVERAL FACTIONS.

There is under 15 days' supply of fuel and food in the place. Villa's men hold Cananea, Carranza's hold Naco, therefore communication is interrupted. The Nogales line is badly in need of repairs. There are no disorders at Cananea. Colonel Beltram being firm. The Greene-Cananea property was closed again on October 26.

PERSONAL

DAVID H. LADD is at Milford, Michigan.

HOWLAND BANCROFT writes from La Paz, Bolivia.

B. V. BARTON has gone from Australia to Korea.

R. A. KINZIE has been in Amador county this week.

J. H. MACKENZIE is due from Juneau on November 10.

C. B. KINGSTON has returned to London from Rhodesia.

LLEWELLYN HUMPHREYS is here on his return from Arizona.

T. C. NOBLE is returning to Butte from southern California.

H. WISENER HAMMOND visited the Tintic district, Utah, recently.

ROY H. ELLIOTT has returned from Siskiyou county to San Francisco.

ROY J. KING returned to Tonopah from Alaska, and is now in Oregon.

FRANK PERRY, manager of the Lluvia de Oro Mining Co., is here from Mexico.

DOWNIE D. MUIR, JR., on his return from Alaska, has gone to Salt Lake City.

CHARLES FARISH, on the staff of the Arizona Copper Co., is visiting San Francisco.

J. H. HEDGES, chief engineer to the Moctezuma Copper Co., is at Long Beach, California.

C. B. LAKENAN, manager of the Nevada Consolidated Copper Co., is here for a few days.

FARIS V. BUSH, of Lordsburg, New Mexico, editor of the *Lordsburg Leader*, is in San Francisco.

W. R. COX has been appointed Professor of Mining and Metallurgy in the Oregon School of Mines.

KEIJITO NISHIO, engineer of the Japanese Bureau of Mines, sailed from San Francisco for Yokohama on October 23.

L. F. S. HOLLAND has returned to Los Angeles after making examinations in Nevada, and in San Bernardino county, California.

H. C. HOOVER arrived in New York on October 24 on a brief visit in connection with the business of the Belgian Relief Commission.

FRANK H. SISTERMANS, DUNCAN M. MUNRO, and ALBERT C. SAVAGE have gone into partnership, with an office in the Mills building, at El Paso.

E. M. HAMILTON, F. A. BEAUCHAMP, and S. E. WOODWORTH have formed a partnership as metallurgists with offices at 419 Embarcadero, San Francisco.

Obituary

HOWARD E. BURTON, president of the Western Zinc Oxide Co. and a prominent and respected assayer since 1890 at Leadville, Colorado, died on October 16 at Glenwood Springs, following five days' illness with pneumonia. Mr. Burton went to Leadville in 1890 as assayer for the Elgin smelter.

Schools and Societies

The FRANKLIN INSTITUTE OF PENNSYLVANIA held a meeting on October 20, at which Heinrich O. Hofman delivered a lecture on 'Recent Progress in the Metallurgy of Copper.'

The California Section of the AMERICAN CHEMICAL SOCIETY held its 86th meeting on October 23, at the Jules restaurant, Market street, San Francisco, at 8 p.m. 'Cast Iron as Applied to Chemical Industry,' is the title of a paper by Edward J. Fowler.

The Columbia section of the A. I. M. E., which includes Idaho, eastern Oregon, eastern Washington, and part of British Columbia, with a membership of 100, is to visit Wallace, Idaho, on November 19 and 20. Interesting papers will be read, followed by excursions.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, October 28.

Antimony	37
Electrolytic copper	19
Pig lead	5.00—5.95
Quicksilver (per flask)	$93
Spelter	16
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	26

ORE PRICES

Antimony: market weaker, 50% product, free from deleterious impurities, per unit.....$1.40
Tungsten: depending on quality, subject to negotiation, minimum 65% WO_3, per unit for spot.....30.00

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, October 28.—The demand for copper is irregular; lead is firm owing to export buying; zinc is active and very strong.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

The silver market continues steady, but the weakness of exchange with England may affect it slightly. Export of silver from London to India up to October 6 totaled £3,380,250, a decrease of about 12,500,000 oz. compared with this period of 1914. India and China show no interest of late. Stocks at Bombay have increased. The stock at Shanghai on September 9 was valued at about $54,000,000, say 110,000,000 oz. Since the War began, £6,000,000 of new British coin has been put into circulation, double the normal annual addition to the currency. This used silver worth £2,150,000, say 22,000,000 ounces.

COPPER

Prices of electrolytic in New York, in cents per pound.

Exports during the week ended October 19 totaled 4,335,622 lb., worth $776,437. England secured 2,543,102 lb. of this and Italy 1,412,234 lb. Imports amounted to 4,634,815 lb., valued at $601,764. Peru sent 2,888,372 lb., and Canada 510,449 pounds.

It is estimated that Michigan will produce 240,000,000 lb. this year, against 230,437,992 lb. in 1905, the greatest year. The present rate is nearly 300,000,000 pounds.

Cerro de Pasco, Peru, has been re-organized by New York capital, by issuing $10,000,000 6% bonds. The present output is about 4,000,000 lb. per month. By the end of 1915 the Chile Copper Co. will be producing 7,500,000 lb. per month. By spring it will be 10,000,000 lb., at a cost of 6c. per pound. On the latter yield the monthly profit will be $1,250,000.

Braden is to issue stock to pay its debt.

Cananea is closed again by the Villa activity in Sonora.

The Calumet & Hecla-Tamarack consolidation scheme has not been agreed upon. The former offers $50 per share, but the latter's engineer estimates its value at $100 per share.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

At Joplin the zinc-ore market was firm last week; production increases. The output of the Missouri-Kansas-Oklahoma region was 5277 tons blende, 240 tons calamine, and 772 tons lead, average $78.68, $51.87, and $50.90 per ton, respectively. The total value was $466,963, and for 43 weeks, $19,394,016.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

ANTIMONY

In the past week there has been an active demand for antimony, and prices have advanced sharply, Chinese and Japanese now being quoted at 33 to 35c., duty paid, with the domestic product at about the same figures. Not only has buying given strength to the market, but the blocking of the Panama Canal has been a potent influence in sending prices up. The 'Kroonland,' which was among the vessels delayed, had 60,000 lb. of antimony aboard. The selling trade professes to know little about domestic antimony, except that it is refined in California, although they admit that it is as acceptable as Chinese and Japanese so far as munitions are concerned.

Eastern Metal Market

New York, October 22.

Copper producers have reduced their prices, though not unanimously. Practically all of the present demand is coming from war contractors. Lake is competing with electrolytic. England has been buying in Spain to evade the unfavorable exchange rate. New mills are being equipped for the manufacture of cartridge metal, and the manufacture of extruded metal is growing in this country. The scarcity of spot and near-by deliveries of zinc continues to give strength to that metal. Lead has been sold heavily for export; some producers are well sold up, and prices have been advanced $5 per ton. Tin prices have taken a turn upward; there is no business of importance in futures, while holders of spot are not willing to sell. Antimony has been active and prices have advanced. Aluminum is scarce at 52 to 56 cents.

Large orders continue to be placed for munitions of war, and the subsequent demand for metal-working machinery is great, in fact, no diminution is shown in the volume of business. The principal orders are for rifles and cartridges, though some big shell contracts also figure. Strikes in machine-tool plants have hampered deliveries considerably, many of which cannot be made in less than nine to ten months, or even one year ahead. In Cincinnati, 26 tool builders were affected, but the trouble appears to be passing, there and elsewhere.

Steel prices are moving upward and 1.45c., Pittsburg, is the common minimum for plates, shapes, and bars, but all the mills are obtaining premiums over this price. Miscellaneous steel products are up from $1 to $3 per ton also. The problem with the steel mills is not that of getting business, but in making deliveries. All are sold up to the end of the year. The export demand is extremely heavy, especially for semi-finished steel and large bars which are used in making shells.

The movement of freight on railroad lines running into New York is the heaviest since 1907. Ocean shipments are equally as heavy.

COPPER

Producers who had been holding their copper at 18c., full terms, for many days, lowered their quotations for electrolytic on October 18 to 17.87½c., 30 days, delivered, or 17.75c. cash, New York; sales were made at the lower price. Lake has been peculiar in that it has competed with electrolytic and at times has been lower by ¼c. At present the two grades are on the same level. Even the best brands of Lake command no premium over electrolytic. Despite the decline of October 18, some of the producers continued to hold at 18.25c., 30 days, delivered, which they have quoted for many days. The continued dullness of the market has apparently given them no cause to reduce their prices, and their attitude is bolstered up to some extent by the fact that European statistics show that French and English stocks decreased 8335 tons from September 15 to October 15. The stock of fine copper in France on October 15 was 1925 tons, against 5177 tons a month previous. This showing caused Standard copper to advance in London, but electrolytic remained at the pegged price of £88. The New York market has not been without business, although the lots taken were of moderate size, and almost entirely to meet the needs of ammunition makers at home or abroad. The failure of foreign exchange to make a better response to the success of the Anglo-French war loan has been a continued cause of disappointment. Demand sterling sold on October 21 at $4.67¼. Because of the high rate of exchange England found that it could buy more advantageously in Spain, and has been doing so. The purely domestic demand is poor, and the entire consumption is not sufficient to take care of production, a condition which, in the opinion of some of the trade, is likely to result in still lower prices.

An interesting recent development is the greatly increased production of cartridge metal. This was to be expected, of course, but the growth in output is greater than was anticipated. Not only have the established mills added to their equipment, but new rolling-mills are being installed. The Western Cartridge Company at Alton, Illinois, and J. B. Wise, of Watertown, New York, are erecting new plants. The latter has a big contract with the Allies. Another development of interest is the growing use of metal-extruding presses in this country, by means of which brass and kindred metals are forced through dies by hydraulic pressure, thereby creating rods and shapes of all kinds in any length desired. The presses used formerly were made in England, but since the War started many have been made in this country, and orders for others are steadily appearing. The process is said to have many advantages over rolling.

Exports of copper October 1 to 22 totaled 13,420 tons.

ZINC

It has been a difficult matter to interest consumers in future deliveries of spelter. Up to three or four days ago they showed but little interest in any delivery, and the market was dull and easy, gathering what little strength it had from the scarcity of spot and near-by metal. In the last three or four days, however, the makers of war materials have entered the market and caused it to take on a decidedly better tone. Prices advanced ½c. between October 18 and 20. The situation was made still better by inquiry from galvanizers for first-quarter and first-half deliveries. The New York quotation for prompt shipment on October 20 was 13.75c., with the St. Louis price at 13.50c. November is quoted at about 13c., St. Louis, December at 12.50c., and first quarter at 10.50 to 11c. Brass-mill special is quoted at 15 to 15.50c. Exports from October 1 to 22 total 4203 tons.

The base price of sheet zinc continues at 16c. f.o.b. mill, 8% discount allowed for cash and carload lots.

LEAD

Heavy buying on behalf of Canadian and Russian ammunition makers, with more interest shown by war contracts in this country also, has imparted no little strength to the lead market, and it surprised none when the A. S. & R. Co., October 21, advanced its price $5 per ton, or to 4.75c., New York. Independent sellers had been asking 4.55c., New York, although the A. S. & R. Co. had quoted 4.50c., New York, and 4.42½c., St. Louis. Some of the export buying was on a basis that netted the sellers 4.75c. f.o.b., New York. Export sales would unquestionably be larger were it not for recent sharp advances in ocean freight rates. Freight room is costly and extremely scarce. The metal is bringing about 5c. per pound in London, and present conditions would indicate higher prices. Some producers are well sold up for the next two or three months. Exports from October 1 to 22 totaled 2221 tons.

TIN

The expectation that Great Britain will impose an export tax on tin continues to restrict trading in futures. Business has been fair in the past few days, and inquiries are larger, but consumers are slow in taking hold. On Monday last about 200 tons changed hands, not much to mention in ordinary times, but attractive just now. Holders of spot have changed their attitude in the last week, and are unwilling to sell, and this stand, with the steady, though small, volume of business has caused spot prices to advance. The quotation October 19 was 33.25c., and on October 20 was 33.50c. The quantity afloat October 20 was 4175 tons, and there had arrived up to that date, 1750 tons. The imports of tin at Pacific ports in August, according to a statement of the U. S. Department of Commerce, totaled 480,908 lb. at San Francisco, valued at $166,606, and 1,940,100 lb. at Washington, valued at $523,782.

BOOK REVIEWS

Directions for Designing, Making, and Operating High-Pressure Transformers. By F. E. Austin. P. 46. Illustrated. For sale by the Mining and Scientific Press. Price, 65 cents.

The author of this work is head of the department of electrical engineering at the Thayer School of Engineering, Dartmouth College, Hanover, New Hampshire, also the author of three books on kindred subjects. In these days of the generation and transmission of high-voltage alternating current some means of reducing the pressure to one suitable for driving motors is of importance, hence the many designs of transformers. The theory, details of construction, cost, etc., are explained. The book is somewhat technical for the beginner, although amateurs should be able to follow instructions given.

Examples in Alternating-Currents. Vol. I. For students and engineers. By F. E. Austin. P. 223. Ill., index. For sale by the Mining and Scientific Press. Price, $2.40.

This work has been carefully prepared, and is published in pocket size. It contains examples dealing with wave-length, frequency, sine and nonsine alternating-currents and pressures, generators, power, power-factor, capacity, inductance, and resonance, showing the process of solution, step by step, together with the fundamental equations applying, and the necessary data properly arranged. The diagrams are very clear, greatly assisting in an understanding of the fundamental principles. Electrical engineers will find the trigonometric formulæ of value, and tables of variable quantities for frequencies from 1 to 150,000 cycles.

Mining and Mine Ventilation. By Joseph J. Walsh. P. 180. Ill., index. D. Van Nostrand Co., New York. For sale by Mining and Scientific Press. Price, $3.

The author is mine-inspector at Wilkes-Barre, Pennsylvania. He has aimed to present a graphic form of studying mine-ventilation, based more clearly on the fundamental laws of physics and chemistry. The first half of the book is taken up largely by explanations of the physics relating to gases, pressures, heat, etc. The theorems and principles of ventilation, methods of determining the proper size for a fan, are stated fully, together with formulas and examples. Although the subject of mine-ventilation has received more attention at coal-mines that at metal mines, there is an increasing tendency to provide for it at large up-to-date metal mines, particularly where heat is a factor. Thus the Copper Queen mine recently put in a system of mechanical ventilation, using the pressure system rather than the exhaust system.

Test Methods for Steam Power-Plants. By Edward H. Tenney. P. 224. Ill., index. D. Van Nostrand Co., New York. For sale by the Mining and Scientific Press. Price, $2.50.

A working exhibit at the U. S. Bureau of Mines' exhibit at the Palace of Mines, Exposition, San Francisco, shows the efficiency of power-plants, using coal, in an impressive manner. In his introduction to this book, which has been prepared as a reference for power-station engineers, superintendents, and chemists, the author says, "Highest economy in the modern steam power-plant is to be gained only through an accurate knowledge of all conditions as they exist throughout the station, both in regard to the materials used in the production of power, and in regard to the equipment itself." Thereupon he discusses the purchase and testing of coal, economy of combustion, boiler water, evaporative tests, testing prime movers, and testing lubricants, all vital subjects for the power engineer. Coal is no longer bought as it was years ago, and power companies demand high-grade fuel. Proper combustion is necessary if efficient results are expected from coal. Boiler water is more or less always a worry to steam users, and the tests and treatment given will be found of value. Evaporative tests should be part of the work of a steam-plant, so here they are discussed; likewise testing turbines. Good oils and greases are indispensable for smooth running of machinery, and their qualities are herein described. The appendix contains the usual tables. Altogether a handy book to have around a plant.

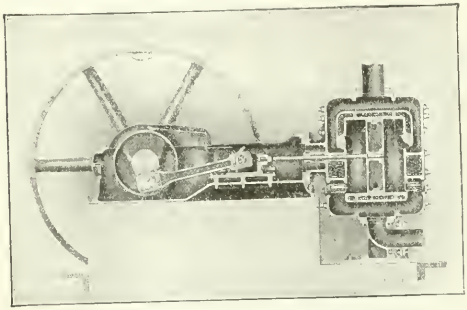
New Machines and Devices

Information based on letters and catalogues from manufacturers.

A New Vacuum-Pump

Vacuum-pumps are generally necessary in power-plants and metallurgical plants, in the latter where filtration is in vogue. For maintaining a vacuum, and for general service in other lines where a high degree of vacuum is desired, the Ingersoll-Rand Co., 11 Broadway, New York, has recently introduced a complete line of steam and power driven, duplex type, Imperial vacuum-pumps.

In general design these machines follow that of the Imperial air-compressors, a type with which engineers and power-plant operators are long familiar. The vacuum cylinders, as will be seen from the sectional illustration, are somewhat different from these ordinary ones. The intake valves are of the Corliss type, so placed in the cylinder head that the clearance is very low. This is a desirable feature, as the air trapped in the clearance spaces at discharge pressure will not reach such a volume, upon being expanded to intake pressure, as to greatly



THE NEW VACUUM-PUMP.

limit the pressure reduction that may be obtained. The action of the valve is positive and quick, and its action being independent of the cylinder and intake pressures, the pressures within and without the cylinder are as nearly equal as possible. The intake ports are large and direct, which, together with the water-jacketing of the valve, tends to cool the intake gases.

The discharge valves, which are of the direct-lift poppet type, are placed in the bottom of the cylinder heads, so that any entrained moisture or water is immediately discharged, a safety feature. Clearance at the point of discharge has been reduced by making the valve partly fill the port in the cylinder head. The discharge passages are also water-jacketed.

The cylinders are said by the manufacturer to meet fully the requirements of satisfactory and efficient operation. The air passages are unobstructed. Tie-bolts pass from head to head, and hold cylinder and heads tightly assembled. Both cylinder and heads are completely water-jacketed, which is said to be an essential feature in the design of vacuum-pumps, as the high ratios of compression tend to create high discharge pressures unless the heat is removed as generated.

Owing to the features described, the manufacturer guarantees the easy maintenance of a vacuum of within a half inch of barometer.

The running gear, that is, the main frame with its enclosed reciprocating parts, the crank-shaft, connecting-rod, cross-head, valve gear and wheel on both belt and steam-driven machines are of the same design as the Imperial air-compressor. Lubrication is by the bath system, providing automatic flood lubrication, yet retaining by the removal of covers from the casing, all the points of accessibility of the open type of machine. When operating, the fly-wheel is practically the only visible moving part, yet the entire mechanism is readily accessible while in motion.

The Imperial pump occupies less floor space than similar capacity machines of the straight-line type, due to its duplex construction, and to the fact that its speed of operation is higher.

These machines are built in capacities from 798 to 7048 cu. ft. per minute, both for atmospheric and low-pressure (5 lb.) discharge.

Commercial Paragraphs

Expansion-joints, tubular-heaters, and cloth-filters are the subjects of Bulletins 11, 13-A, and 14, respectively, of C. F. Braun & Co., San Francisco.

The American Cyanamid Co. announces the opening of its general offices at 200 Fifth avenue, New York City. The Nashville and Buffalo offices are closed.

The Oliver Continuous Filter Co. reports that it has sold two 12 by 12 ft. machines to the Anaconda Copper Mining Co., and one 10 by 12-ft. to the Dietsgen Copper Co., Alaska.

Hamilton, Beauchamp, Woodworth, Inc., metallurgical engineers for flotation and cyaniding, mill design and construction, have a test plant at 419 The Embarcadero, San Francisco.

The adaptation of Parral tanks for oil flotation is the subject of a 10-page pamphlet by Bernard MacDonald of Los Angeles. It includes two pages on the Parral tank system of agitation.

In Bulletin 1432-A, of 52 pages, the Allis-Chalmers Manufacturing Co. of Milwaukee, Wisconsin, has published an interesting lot of matter about its stamp-mills and accessory machinery for free-milling gold ores. Needless to say that the latest is given, including cams and cam-shafts, wood and iron guides for stems, screens, feeders, shaking copper tables, amalgam squeezers, California batea, clean-up pans, retorts, molds, and pebble granulators for re-grinding middling for concentration. Complete specifications give the necessary equipment for a 10-stamp mill.

The Westinghouse Electric & Mfg. Co. announces the following more important among the large number of awards received at the Panama-Pacific Exposition: The grand prize, the highest possible award, on the 4000-hp., 650-volt, direct-current, double-unit Pennsylvania electric locomotive mounted on a turntable under the dome of the Palace of Transportation; the medal of honor on alternating-current and direct-current industrial motors and control apparatus, on precision instruments, on Le Blanc condensers, on motor-generator sets for moving-picture machines, and on high-voltage oil-switches; the gold medal on a number of different classes of apparatus among which are steam turbines, alternating and direct-current generators, alternating and direct-current railway motors, transformers, rectifiers, starting, lighting, and ignition systems, switchboards and accessories, and mining locomotives; a number of silver medals and bronze medals were also received; and the Company was also awarded the gold medal for the most complete and attractive installation in the Palace of Transportation.

EDITORIAL

T. A. RICKARD, Editor

WAR ORDERS are helping 'preparedness,' by causing munition plants to be brought to a high pitch of efficiency.

COPPER EXPORTS of 25,359,000 pounds during the week ending October 16 constitute a record. Of this export France took 11,603,000, England 6,460,000, and Russia 4,625,000 pounds. In March 1914 the export of copper reached 96,519,947 pounds.

ACTIVE demand for all the metals characterizes the New York market, as will be seen from the interesting letter by our regular correspondent on Manhattan island. We believe his quotations of metal-prices to be more reliable than any others accessible to the public.

THE kind of oil to be used in flotation has been determined largely by the local supply; thus eucalyptus oil is employed in Australia, camphor oil in Korea, and pine oil in Utah. The testing of oils will become a part of the duty of the flotation chemist, for the adulteration of oils is common.

SUBSCRIPTIONS received by us in aid of Russian refugees at Moscow, in response to the telegraphic appeal of Mr. E. T. McCarthy, published in our issue of September 18, amount to $1000. We have remitted $700 to Mr. H. C. Woolmer at Moscow, and hope to be able to send as much more.

HEAVY consumption of steel presages a larger demand for copper. It is estimated that the orders for munitions of war already placed in the United States will consume an amount equivalent to 10% of the copper production, 7% of the spelter output, and 20% of the lead production in this country in 1914.

SEVERAL readers have written to correct the error made in the article on 'Soroche and Verrugas,' in our issue of October 2, wherein a railway "from Valparaiso to Oroya" was mentioned. Valparaiso should be Callao. We cannot pretend that it was a typographical error; both the author and the editor knew better, but overlooked the blunder. We thank those who were kind enough to take the trouble to write on the matter.

CYPRUS, which has been offered to Greece by England in exchange for active military support, is interesting to the miner as one of the ancient sources of copper; in fact, the word 'copper' is derived from the Greek equivalent for Cyprus, namely, *kupros*. And it produces copper still. A recent consular report, from Alexandria, states that an American syndicate is operating at Skouriotissa, in Cyprus, by permission of the Government, and expects to build a railway from the mines to the port of Karavostassi. It will interest our readers to know that the syndicate consists of two American engineers.

MEXICAN affairs have made no progress worthy of mention during the past week, but the fighting in progress at Aqua Prieta, just across the border from Douglas, Arizona, promises to end the career of Villa. Should he be defeated and his forces dispersed, we may hope for a rapid improvement in political conditions throughout Northern Mexico.

WE extend our compliments to Mr. Charles McC. Anderson, who is keeping his flag flying over the office of the *Mexican Mining Journal* even in days so catastrophic, especially in Mexico, Poland, and Servia. In the last issue of his journal we note sundry interesting ruminations by Colonel Tepetate. The last one recorded strikes a responsive chord: "I wish I could hibernate, like a woodchuck or a bear, for a couple of years. This [world] is no place for a man of sense."

DURING recent weeks our outer office has received an extraordinary number of new subscriptions, eclipsing all previous records. Undoubtedly some of them were due to the resumption of prosperity in mining; but we also like to think of them as partly the result of a wider appreciation of the efforts of our contributors, correspondents, and editors to make the PRESS interesting and helpful to the men who have to do with mines, mills, and smelters. We extend a hearty welcome to the new readers.

ACCIDENTS in metallurgical works is the title of a report just issued by the United States Bureau of Mines. It covers the years 1913 and 1914. During that period 119 men were killed and 2285 seriously injured in smelters and mills, representing rates of fatality equivalent to 1.55 and 29.67, respectively, per 1000 men employed. The report does not include returns from all the plants in operation; notably it excludes iron blast-furnaces; but the statistics show a progressive gain in their approach to completeness and afford another evidence of the good work being done by the Bureau.

PATENTS are numerous in these days. We give notes concerning the most recent issued to metallurgical inventors. Among them are several kinds of flotation apparatus, one patented by Messrs. A. H. Higgins and W. W. Stenning, of Minerals Separation, Ltd., another by Mr. Robert S. Towne, and a third by Mr. Thomas M. Owen, who has applied his inventive ability to preferential flotation. Among the crushing devices is a modifica-

tion in his ball-mill by Mr. Frank E. Marcy, and among dewatering machines is one by Mr. Wilton E. Darrow, both names familiar to mill-men. Indeed the list we publish in this issue is particularly interesting.

OUR London contemporary, *The Mining Magazine,* has come into conflict with the Institution of Mining and Metallurgy over the project to start a register of reports and other information on mines. Whether engineers have a right to dispose of a report, other than to the client for whom it was made, is a moot question, concerning which we are asking for an expression of opinion. It may be that the starting of 'The Mining Register' was not timely; it may be that it transgressed sundry British notions of propriety; but it did receive considerable support from both sides of the Atlantic and it was meant to be of service to the profession. However, the Institution saw fit to interfere in the matter. This is interesting as indicating the recognized authority of the Institution in professional affairs. No technical society in America could expect successfully to call the publisher of a technical periodical to order under like conditions, and while the Institution has made good its objection, may we not assume that this result was due largely to the good sense and professional spirit of those controlling the *Magazine?* We do assume it, confidently. The episode does credit to both.

THE discussion columns are enlivened this week by a letter from Mr. H. Stadler replying to sundry comments and criticisms on his paper explaining the mechanical efficiency of crushing. Certainly he makes a crushing rejoinder, illustrating an extreme phase of the law of Kick, of which it may be said that it is more truly "Stadler's theory" than what is commonly known as Kick's law. Whether Rittinger's theory, on the other hand, is "the law of cracks, or cranks" we leave Mr. Stadler's opponents to decide, but it is quite evident that either form of statement is beyond the reach of apparent typographical error. We submit that Kick's law, or the law of Kick, is being stretched to "the elastic limit" and that it may lead not only to the fracture of prisms but to the cracking of the cocoa-nut that crowns *homo sapiens.* However, we are grateful to Mr. Stadler for giving a touch of real life to our pages. We undertake to respond for Messrs. Kenney and Del Mar so far as to say that both of them, of course, would have been highly offended if Mr. Stadler had "completely ignored" them; indeed, the measure of their gratification will now overflow, seeing how thoroughly he has attended to them. Yet we hasten to say that Mr. Stadler is personally known to the present writer as a diffident and amiable investigator who always leaves his gun at home on the piano when he attends a scientific meeting. He is the quietest mannered man that ever sunk a submarine or exploded a mine under a hostile batallion. And what is much more to the point he understands his subject and is as keen in the search after truth as a golfer after a lost ball. Therefore, gentlemen, Messrs. Kenney and Del Mar, count twenty before you reply; please make your counter-attack without the use of chlorine gas, hand-grenades, bombs, or any weapons not recognized by Hoyle, Cavendish, or the other authorities on the game.

PUBLICITY AGENTS have proved such a useful adjunct to theatrical companies and other enterprises that depend on public support that the idea involved has been adopted by a surprising variety of organizations. The Standard Oil Company, for example, employs an agent whose duty it is to see that such facts regarding that corporation are published as well serve to correct misleading or malicious, or even true, assertions made by the scribes of the daily press. Most of the Government bureaus at Washington retain alert men whose duty it is to employ all available means to acquaint the general public with what is being done by these bureaus, the purpose being twofold: to familiarize the community at large with the knowledge that has been made available, and to create the impression that the country is getting a useful return for the expenditure of national funds, thus paving the way for appropriation for the continuance of the work. Universities, especially those supported by the State, make use of publicity men to the same end. On the whole, a good purpose is served by these activities, and the general idea is commendable. Its practicable application, however, has introduced some marked disadvantages. A pocket-knife may be a useful present for a small boy, but when it is first given to him he is likely to try it on the furniture and other objects considered by his parents unsuitable for whittling. The fundamental trouble is the difficulty of securing a man with the right combination of qualities for the work of publicity. Sometimes a member of the organization is detailed for the purpose, with the usual result that, not being a practised writer, he is unable to present the facts in a way sufficiently interesting to warrant publication of them, or to induce the public to read them. In other cases an ex-reporter is employed who is able to make his loose matter readable but objects to being handicapped by facts. The former does not succeed in obtaining publicity; the latter obtains publicity of an undesirable sort, which sometimes serves to make ridiculous, in the eyes of serious men, the organization that he represents.

Kyshtim

Mining in Russia, particularly in the hinterland of Siberia, has not suffered from the consequences of the War as much as regions nearer the scene of hostilities; in fact, some of the consequences of "the pentecost of calamity" have been favorable to those operating in Siberia. A fair example is afforded by the experience of the Kyshtim Corporation, a copper-mining enterprise developed by English and American capital, under the guidance mainly of American engineers. At the beginning of the War a shortage of labor was caused by the mobilization of one-third of the employees; at the same time both railway and ordinary road transport became precarious. The supply of coal, used in smelting and

mining, was commandeered by the Government. This came from a colliery 55 miles from Kyshtim; since then the company has exercised an option on coal-lands only 2½ miles from the main line of railway, and thus has opened up an abundant supply of the requisite fuel. As our readers are aware, the Russian import duty on copper gives the domestic producer a net bonus of £30 or $145.50 per long ton above the London or New York price. Up to July 13, 1915, the Kyshtim Corporation obtained £102 10s. per long ton, or 22 cents per pound, for its copper, this being £10 or $48.50 better than the average for the whole of 1914. In August this year the price obtained was £133 per ton, or 28½ cents per pound, so that in this respect the War has proved a favorable factor. Moreover, the Kyshtim Corporation has been requested by the Russian government to erect works capable of producing 8000 tons of sulphuric acid, the cost of this plant to be advanced by the Government. At the annual meeting of the company in London it was stated that the first two years' output of this acid has been purchased already at a satisfactory price. Large orders for pyrite, as a source of sulphur, have been placed by the Government, hence the production of this mineral has been increased to 1000 tons per week. Finally, the Government is negotiating with the company with a view to the manufacture of munitions, as the Niaspetrovsk iron foundry of the Kyshtim Corporation is well equipped and is famous for its beautiful wrought-iron products. During the last financial year the Kyshtim produced 7588 long tons of copper, which, with the iron and timber output, yielded a gross output of £1,059,523, of which £367,443 was net profit. The consulting engineer, Mr. R. Gilman Brown, estimates 2,031,000 tons in reserve. In 1914 the average yield was 2.87% copper, besides 1.8 dwt. gold and 1.1 oz. silver per long ton. This group of mines is said to be in a position to produce 10,000 long tons of copper per annum. The cost of cathodes in 1914 was £42 1s.10d., against a sale price of £92 10s.10d. per ton of copper, so that the margin of profit was handsome.

The Strike in Arizona

The relations between capital and labor are difficult to discuss, because they involve not only an economic but a political problem. Any frank discussion is bound to give umbrage to one side or the other, usually both. No statement intended to be fair can proceed far before it begins to tread on the intellectual corns of the disputants. Yet we deem it a duty to ventilate the subject, believing that we may be able, from our detached point of view, to contribute to a better understanding, at least among mining engineers, who stand between the upper and the nether millstones of capital and labor.

The strike in Arizona is a good example of such disturbances. It continues without hope of early settlement. The Department of Labor, we are glad to see, has ordered an investigation and a commissioner has been ordered to Clifton, to co-operate with two representatives of the copper companies and two representatives of their employees. While it is difficult to ascertain the facts, it would appear as if the men had some cause of complaint in the low rate of wages. Underground labor, mostly Mexican, was being paid as low as $1.75 per day, on the basis of 13-cent copper. This compares with a minimum of $3 per shift for white miners at Miami or Butte on the same market basis. But the comparison is misleading on account of the cost of living. That is a mistake often made. For instance, a miner in North Carolina may live better and yet save more on $2 per day than one receiving $4 per day in Montana. The cost of living varies enormously between different mining communities. Thus the white miners on the Rand get the equivalent of $6.50 per day, but the purchasing power of money at Johannesburg is so much smaller than it is at Grass Valley, for instance, that the same man in the latter district working at half the Rand rate will have more to show at the end of ten years. The rate of wages is a local question. From the manager's point of view a direct comparison is unfair because of the vast difference in efficiency. The Mexican labor employed in Arizona is not nearly as good as that obtaining in Montana; the white miner is bigger, stronger, and more intelligent than his fellow-human from beyond the Rio Grande.

The rate of wages prevailing at Clifton and Morenci might not have precipitated a strike if the cost of living had not been increased to the Mexicans by the fees exacted for hospital and water service, and by the compulsion to buy their food and clothes at the company store. This is not the first time that the store business of mining companies has proved an irritant; it is apt to be conducted with much of the clumsiness of municipal and governmental efforts to manage public utilities, and its real profit is not usually disclosed with any degree of frankness in annual reports, in which charges for depreciation and other devices of book-keeping tend to obscure the real results. On top of the store nuisance, the Mexicans complain that the wages paid previous to the strike varied under different foremen, leading to discriminations that were frequently irritating and not always just.

There is another phase to be considered: the operations of the three companies are variously remunerative, so that they are not alike able to pay higher wages. Although the Shannon Copper Company made a profit last year, it has operated on a narrow margin for many years previous; the other two are believed to be in a healthy financial position, notably the Arizona Copper Company. Regarding the Detroit not much is known, it being a subsidiary of a much bigger corporation, Phelps, Dodge & Co. Undoubtedly a minimum scale of $3 per shift, for underground work by Mexican labor, would compel the Shannon to cease working. Again, miners usually have exaggerated notions of the profitableness of operations. So has the public. Both overlook the big sums of money spent on development and plant; they hear about dividends, but they fail to recognize that until the capital has been redeemed—and that does not happen soon or often—the dividends represent merely a return of the

original investment, or, more correctly, the primary stake in the speculation. The equipment, which may represent millions of dollars, goes to the scrap-heap when the mine is worked out, usually sooner, for both plant and equipment have to be replaced at relatively short intervals. These factors must be considered by a dispassionate inquirer, but they are, not unnaturally, ignored during the heat of a strike. So also is the fact that the cost of working rises wherever and whenever a spirit of discord and mutual recrimination obtains in any industrial operation. A strike, whether won or lost, is a heavy tax on both sides, like warfare itself. Any adjustment finally effected is usually such as could have been made peaceably without the loss of time and temper.

Law and Patents

Flotation is represented in this issue by a second instalment of the transcript of oral argument presented in the recent trial of Minerals Separation *v.* Miami. Under date of October 16 we gave an excerpt from the speech by Mr. Walter A. Scott, of counsel for the defendant; on this occasion we give excerpts from the speeches of Messrs. Henry D. Williams and W. Houston Kenyon, counsel for the plaintiff. We publish these because they are not accessible to our readers and because they are highly illuminating, not so much as throwing light on the merits of the case under litigation, but as affording a reasoned discussion of the scientific principles involved. The colloquies between counsel and Court are particularly interesting, for they illustrate the effort of clever laymen to understand physical phenomena of an obscure character. The judge, of course, knows nothing about the recent technology of the subject; the lawyers have learned most of what they know from the expert witnesses on their own side; some of the lawyers and some of the witnesses have taken part in previous suits involving the same questions, so that they have become thoroughly informed concerning the main points at issue. A big lawsuit is an education in itself. As for the witnesses, many of them are directly interested in the decision, they are either partners or employees of the litigants, so that their testimony becomes skilful advocacy. Even the outside witnesses, or experts, are retained by one side or the other, and, however scientific in their first attitude, they must become thoroughly partisan as the case proceeds. Thus the entire effort of arriving at the truth is severely handicapped; it is a clumsy method of trial, consisting essentially of the delivery of a large mass of partisan evidence before a judge inexpert in the science of the patents and operations involved. At the same time, we must recognize that all human experience goes to show that one of the best ways of arriving at the truth is for two partisans to argue their case before an impartial third person. But that third person might well be versed in the subject matter of the dispute, so as to understand the evidence, as well as the arguments, of the two disputants.

The metallurgist may be forgiven a feeling of impatience, if not disdain, at the whole performance. Why should not the Court consist of one or of three scientific men of special experience, why should not the witnesses be chosen and retained by the Court, still keeping trained dialecticians, namely lawyers, to argue the case? The answer is that the issue is primarily one of law, not of technical science. Then perhaps a good compromise could be effected by having special judges with scientific and technical knowledge to sit in such patent cases. As to the witnesses, of course, nobody can deny that these should not be in the pay of either litigant but retained by the State. Such a scheme would in time produce men of proved intellectual honesty, keen scientific insight, and judicial temper. Meanwhile we must accept things as they are and acknowledge that these flotation cases have been tried with great skill on the part of all concerned. But does it not seem absurd when the Government gives the inventor a specific privilege, namely, the right to use or lease his invention, that he should be put to such expense and trouble in protecting the right previously accorded to him by law. Manifestly, the Government should not grant the privilege without thorough investigation, without advertising for objections, without the fullest publicity to all concerned, but, having once given the privilege, the Government should stand behind the patentee and protect him fully against infringement. Next, it should assume the duty of specifying the proper royalty to be collected by the patentee, modifying the impost from time to time according to circumstances and preventing an excessive imposition. Perhaps also it might be well if the Government took part of the royalty to meet the expense of the special administration required in such matters. If these things were done, then, of course, any quarrels over patent-rights would come for adjudication before the Patent Office administration, which, by that time, would include a court suitably equipped to try such cases. As it is now, not only do we have scientific problems discussed before non-scientific tribunals and hired witnesses, not only is the patentee helpless to prosecute infringements unless he is also wealthy, but the very act of patenting is a farce. In applying for patent an inventor is supposed to state plainly what his invention really is, and to explain clearly what is the nature of his claim. In fact, many patentees—including some of those privileged to use certain phases of flotation—take care to give as little information as possible and to render their description of the minimum practical value. That is why an infringement may be an innocent infraction of the patent. This failure to give explicit information marks an effort by the patentee to protect himself in default of protection from the Government. In the case of flotation, it is obvious that many of the obscurities of phraseology are due to the obfuscation of the patentee's mind, for most of the supposed inventions have been made not by deduction from scientific principles, but by 'trial and error,' by the 'hit or miss' of laboratory empiricism, yielding results that the patentee is not able to explain and leading to inferences that he is unable to maintain. So, once more, we rise to remark that the patent law is an excavated anachronism.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Mechanical Efficiency of Crushing

The Editor:

Sir—At first I was of opinion that the two articles recently published in your paper by Mr. H. C. Kenney and Mr. Algernon Del Mar were not worthy of a reply. However, having paid so much attention to a paper of Mr. A. O. Gates on the same subject, just now under discussion before the American Institute of Mining Engineers,† they might feel offended if I should completely ignore them.

Mr. H. C. Kenney* was one of those who lectured to Mr. Gates on his failure to realize that in the case of shearing, mentioned by him, a change of configuration would infallibly precede final rupture. Immediately after he plays the same trick in a better disguised form. He cuts the cube by a "sharp and strong theoretical knife (since we are dealing in theories) that would sever the molecular bonds without causing compression or distortion." The theory of the action of the knife is that of the wedge, the effect of which can easily be studied by cutting a piece of cheese. I am quite prepared to see the next expert turning up with a theoretical saw to prove that the work expended is proportional to the area of fracture.
